THE Cambridge School of Veterinary Medicine is derived substantially from ideas and recommendations contained in the two reports of the Loveday Committee on Veterinary Education in Great Britain (1938, 1944). Before this, however, in 1923, a chair of animal pathology had been established, and Prof. J. B. Buxton appointed as the first professor and director of the Institute of Animal Pathology. Later, in 1935, the University, in consultation with the Royal College of Veterinary Surgeons, proposed a scheme for courses in the pre-clinical subjects which would lead to certain exemptions from the examinations for membership of the Royal College and to a postgraduate diploma, after qualification and registration had taken place, the final two years being spent at one of the existing veterinary schools. The first report of the Loveday Committee approved the 1935 scheme; but in 1944 the same committee decided to go further and recommended that all veterinary schools in Britain should become integral parts of universities. It also proposed that a School of Veterinary Medicine should be located at Cambridge which would provide both pre-clinical and clinical training, and would lead to a degree in veterinary medicine. These recommendations were accepted by the Ministry of Agriculture and by the University.

In 1947, the chair of animal pathology which Prof. T. Dalling had vacated during the War was filled by the appointment of Prof. W. I. B. Beveridge, and he became the director of the Institute of Animal Pathology. This Institute continued actively to pursue research into the diseases of animals. In 1949 the Institute became a departmen within the Faculty of Biology 'B' of the University

In 1950, the present writer was appointed at the first professor of veterinary clinical studies, to organize a new Department within the Faculty of Medicine. These studies were to comprise all those subjects usually included under the broad headings

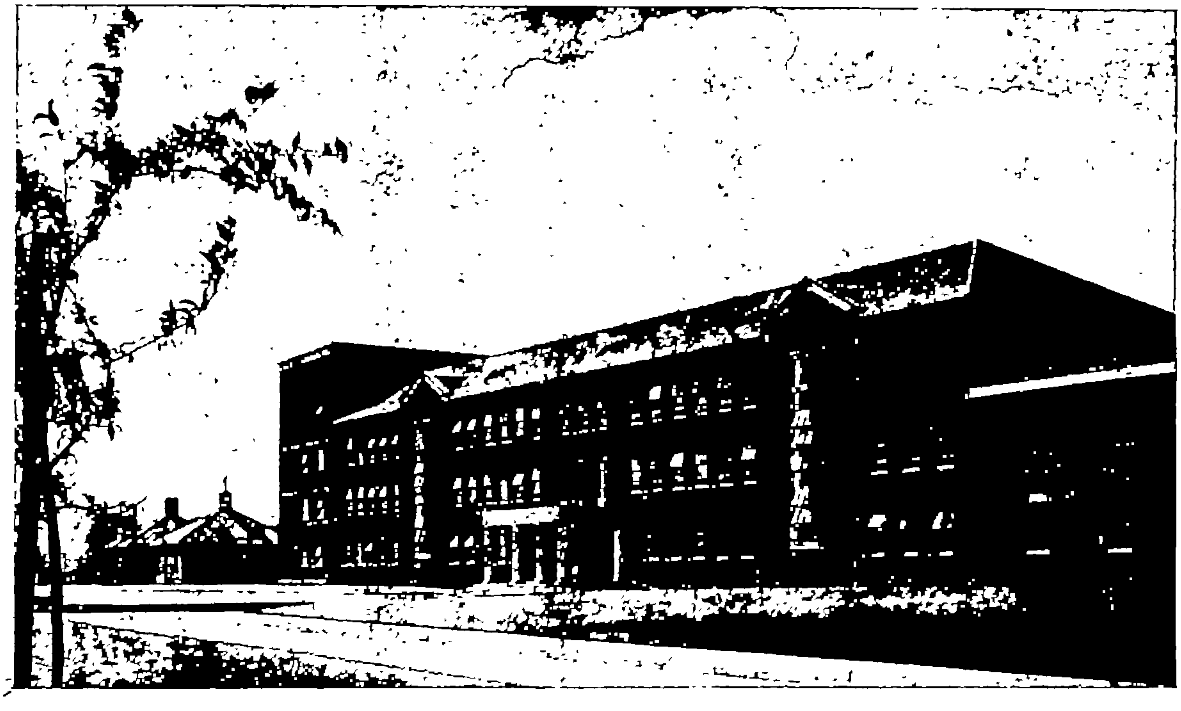

Fig. 1. The Veterinary School, Cambridge. Main teaching and research block, with the end of the hospital on the left.

Fig. 2 Unposed photograph of an operation on a dog in progress

of animal health, animal surgery and veterinary medicine.

The buildings of the new Veterinary School, which were opened by H.M. The Queen on October 20, are located within two miles of the city centre on about ne hundred and twenty acres of farm land. Here e Departments of Animal Pathology and Veterinary nical Studies are ideally situated both for teaching d research into the diseases of livestock and, at e same time, are able to maintain a close association with the other cognate sciences.

There are obviously two pre-requisites for teaching and research into veterinary problems: (1) an adequate supply of normal animals, for the study of the maintenance of health; and (2) an ample supply of clinically affected animals. The first requirement was met by getting together a dairy herd, sheep, pigs, ponies, and poultry in suitable numbers. These farm animals provide material for studies of the normal which, for the student, must precede an introduction to the sick. The techniques of the physical handling of animals, their management singly or in groups, nutrition with all its variations, breeding, pregnancy and parturition, observations of behaviour and the functioning of the healthy body, production of milk, and so on, are exercises conducted for purposes of training. The second requirement, clinical material, has been met largely by providing a veterinary hospital service to the practitioners in the surrounding counties. Operating theatres, rooms for radiology and other specialized types of examination of patients have been set up and are now in full use on a consultative basis. A large clinical-pathology section has been formed in the Department of Veterinary Clinical Studies which will act as the natural liaison between that Department and the Institute of Animal Pathology.

Team research into the disease problems of farm livestock will constitute an important part of the programme of the School. Already research into such varied subjects as virus pneumonia of pigs, hæmolytic disease of the new-born, parasitic diseases of cattle and sheep, respiratory and other diseases of birds, are all being actively studied.

The establishment of a veterinary school, fully functioning in all its varied interests, must certainly take time. Building delays have unfortunately resulted in the first graduates of the Cambridge School obtaining their degrees before the completion of the teaching block. Those that follow them will reap the benefit of being able to work in the finished buildings in which all the interests of the Departments have been congregated.

---

Prof. Pugh has set forth his aims and ideals in his inaugural lecture given in Cambridge on March 8*. He traces the inception of the idea of a school for clinical veterinary studies to Sir Clifford Allbutt, regius professor of physic in the University of Cambridge for thirty-three years until his death in 1925. Allbutt constantly advocated a *rapprochement* of studies relating to the diseases of man and animal. In Oxford there was a similar movement due to Sir Henry Acland, regius professor of medicine there. The first step towards this end was the establishment of a chair of animal pathology in Cambridge; but there the matter rested until shortly before the Second World War, when a scheme for veterinary education similar to that followed by medical students was prepared. This opened the way to fulfilment of the recommendations of the Loveday Committee.

Clinical studies, broadly speaking, comprise preventive and curative medicine. Preventive medicine has arisen largely from a knowledge of causal agencies, and it has led to an appreciation of the social significance of human medicine and the economic significance of veterinary medicine. With the decline in economic importance of the horse, the interest of the veterinarian has turned towards farm animals and their place in agriculture. In curative medicine similar methods have been applied in both human and veterinary medicine. But the practical side of veterinary medicine must depend more on economics than sentiment, and will increasingly lean towards the maintenance rather than the restoration of health—that is, preventive medicine.

The knowledge of the clinician is based on the advances made by workers in many branches of natural science, mainly in university institutes; and his tendency to become an empiricist must be resisted. The exact observation and measurement of disease and the experimental study of its processes must not be separate disciplines. Here the veterinarian has an advantage, in that experimental conditions can be maintained. Nevertheless, the veterinary hospital functions as any other teaching hospital, and the ethical obligations and limitations are comparable to those accepted in human medicine and surgery.

The common ground existing in the study of disease processes in man and animals is the attempt to interpret disease in terms of function and func-

tional co-ordination. To place the Department of Veterinary Clinical Studies in the Faculty of Medicine of the University of Cambridge is thus a step towards the comparative approach to medicine. The clinician has already learned to go to the pathologist and biochemist for aid, and it is regrettable that he has not turned more often to the physiologist. The latter works particularly with the dog and the cat—two animals with which the veterinarian is concerned—and it is time that many of the findings with laboratory animals should be extended to the farm animals.

Prof. Pugh concludes as follows: "Basically there are two problems. Is there a place in the intellectual structure of this University for a clinical department, and is there a place for a veterinary school? I hope that the opinion advanced may at least 'provoke those it cannot convert'.

"I have tried to express the aim that veterinary medicine must develop its own science of experimental medicine; I have suggested an approach to this problem in the hope that not only will it enlarge our understanding of disease, but will make for a closer relationship with the other scientific disciplines and create a logical sequence of ideas in teaching. In pursuing this object, the veterinarian's interest in different animals suggests that it is ultimately by a comparative approach that a clinical department can best play its part in the furtherance of knowledge and that, by this approach, the fundamental similarities and dissimilarities between species, in which I include man, may be profitably exploited".

# CAVITATION IN HYDRODYNAMICS

Cavitation is a subject of growing scientific and technical interest, and the first international symposium to be devoted entirely to it was organized by, and held at, the National Physical Laboratory, Teddington, during September 14–16. The word itself was coined sixty years ago by R. E. Froude to describe the process which he visualized as responsible for the unexpectedly poor performance of high-speed propellers fitted to a naval vessel just then completed; his imaginative speculation that the very low pressures existing in some regions of the flow through the propeller caused the formation of cavities in the water was soon shown to be correct by Parsons, and since then naval architects have frequently been concerned to detect and overcome the harmful effects of this breakdown in homogeneous flow. The same problems were later found to occur in hydraulic machines, and more recently cavitation phenomena have become important in such different fields as ultrasonics and underwater projectiles and explosions. This has naturally led to more detailed study of the basic mechanism of cavitation, and during the past few years much has been learned about the behaviour of individual cavities and the factors which control their inception, while considerable progress has also been made in understanding the nature of erosion damage due to cavitation.

It was because of this recent increase in research on cavitation problems that it was considered appropriate to hold a symposium at Teddington to discuss the progress made; because of the special interests of the Ship Division of the National Physical Laboratory, the problems of cavitation in hydrodynamics were selected for special examination, and the programme of the meetings was designed to proceed from discussion of the fundamental physics of the phenomena to consideration of the hydrodynamic effects of cavitation on performance and damage, and to methods recently developed for their study. The symposium was divided into six half-day sessions, at the first of which an opening address of a general nature was presented, while the other five sessions, at which a total of twenty papers was given, were each devoted to a different aspect of hydrodynamic cavitation. In addition to these formal meetings, a further informal session was arranged during the symposium to meet the wishes of those particularly interested in ultrasonic cavitation for a discussion of their problems. A total of about a hundred and thirty delegates from fourteen countries attended the meetings, of whom more than half took an active part as authors of papers or as contributors to the discussions. Special care was taken to give adequate time during the sessions for discussion by firmly limiting each author to fifteen minutes when presenting his paper, and several of the ensuing discussions were extremely lively and instructive. The symposium proceedings, including summaries of these discussions, will be published by H.M. Stationery Office in about six months.

The opening address, given by Mr. P. Eisenber (United States Office of Naval Research), was critical review of recent progress in cavitat research, and discussed the origin and stability entrained gas nuclei and their effects on incepti the influences of turbulence and boundary-layer flo conditions, the present knowledge of the dynamics of transient and steady-state cavities, and the status of research on theories of cavitation damage. He concluded that during the past few years there have been two main accomplishments: the basic problems have been more sharply defined, and the physical phenomena that must be considered in their investigation have been more clearly identified. Mr. Eisenberg emphasized that the questions awaiting answer for immediate engineering application are the very ones which require an understanding of some of the most complex and least understood phenomena in hydromechanics. The chairman, Dr. J. F. Allan (superintendent of the Ship Division of the National Physical Laboratory), commended this conclusion, and forecast that developments in ship propulsion would bring cavitation into more prominence and accentuate the need for practical solutions to its difficulties.

The second session, with Dr. R. W. L. Gawn (superintendent of the Admiralty Experiment Works) as chairman, was concerned with the factors governing inception of cavitation. The effects of dissolved and entrained gas content, the ability of water to sustain considerable tensions under dynamic conditions, and the growth of gas nuclei, particularly those in boundary-layer flows, were the main topics of discussion. It was clear that a means of determining the spectrum of entrained bubble size in flowing water was much needed, and that acoustic methods, often used as criteria of cavitation inception, offer possibilities in this direction. This discussion led naturally to the consideration of experiment techniques, the subject of the next session, at which Prof.

W. P. A. van Lammeren (Netherlands Ship Model Basin) was in the chair. Instruments for measuring fluctuating forces, pressures and velocities and others specially developed for new Admiralty large-scale test facilities were described, while one paper gave details of high-speed photographic methods (with pictures taken at rates of up to 1 million per second) designed for studies of individual bubbles in ultrasonic cavitation, which have a life-cycle, during which intense collapse pressures are generated, encompassed in 1 μsec. A paper outlining the performance characteristics of a small experimental water tunnel led to a vigorous discussion of the virtues of re-absorption devices (inelegantly but widely known as resorbers) in large-scale cavitation testing rigs. Many new water tunnels, including a large new propeller tunnel to be built for the National Physical Laboratory, incorporate expensive resorbers, and the general consensus of opinion seemed to be that these are desirable provided sufficient money is available.

Even large test facilities for ship propellers and water turbines can only handle models which are small compared with their prototypes, and thus scale-effect factors are of great importance in cavitation studies. The papers at the fourth session of the symposium, under Prof. J. W. Daily (Massachusetts Institute of Technology), dealt with this thorny problem, and the relative importance of the significant parameters, particularly the Froude, Reynolds and Weber numbers, was discussed. One paper gave some disturbing preliminary results from a series of geometrically similar model propellers, and another showed remarkable Admiralty photographs of propeller cavitation patterns taken during ship trials of a destroyer and other naval vessels. The following session, with Mr. F. S. Burt (Admiralty Research Laboratory) as chairman, was concerned with a related problem—the effects of cavitation on the hydrodynamic performance of foils. Valuable data on the properties of hydrofoils under super-cavitating conditions (when fully developed, steady-state cavities spring from the leading edge) were given in a group of papers and supplemented in the discussion. A pleasant, and valuable, interlude here was an excellently produced film, with full colour and sound, showing some of the pioneering work being done at the California Institute of Technology. Finally, the delegates turned their attention to the vexed question of cavitation damage, and the papers delivered at this session presented very different views on the mechanism of damage erosion, the upholders of the two schools of impingement attack and corrosion fatigue being in evidence. The qualities of cathodic protection as a damage inhibitor, and the role of gas in water as a damage 'cushion', were also argued. The damage potential of cavities of fixed type, shown to have a fiercely periodic nature with violent downstream collapse conditions, was also brought out; and if this session cannot claim to have resolved the opposed views, it certainly did much to clarify them. Mr. Eisenberg, chairman at this session, persuaded Prof. J. Ackeret (Zurich), a pioneer in this field, to remind the delegates of some highly pertinent effects of shock waves in causing damage, and in his own closing remarks commented that the programme of the symposium had clearly brought out the central problems for discussion. Dr. Allan, responding for the National Physical Laboratory, regretted that the delegates had had to remain almost silent on the problems of cavitation noise; but hoped that in spite of this the meetings would encourage further research which would extend our knowledge and control of cavitation phenomena. Dr. Allan felt that this research should not be organized on an internationally agreed programme, perhaps not even on a national basis, but that individual workers should pursue their own interests and meet at intervals to exchange views. This suggests that the first conference on cavitation problems will be followed by others.

A. Silverleaf

# DEATH AND THE AFTER-LIFE

The general theme, "Disposal of the Dead, and Beliefs in an After-Life", was selected as the main part of the programme of Section H (Anthropology and Archæology) at the recent Bristol meeting of the British Association, because experience had shown the need for a common topic about which anthropologists and archæologists desired each to hear what the others had to say, and the theme chosen provided scope for participation by nearly all elements in the section. With one or two exceptions, the papers were grouped in the sessions as indicated by the headings.

## From the Origin of Man to the Mesolithic Period

The evidence from pre-Neolithic peoples was discussed in the opening session by Dr. Kenneth Oakley, Mr. Miles Burkitt and Dr. L. H. Wells. In his paper on "Earliest Evidence of Disposal of the Dead", Dr. Oakley remarked on the tendency, among gregarious non-human primates, for the dying animal to leave the sleeping-place of the troop. He then dealt with cannibalism, which was widespread before disposal of the dead by ceremonial or careful burial became regular. All the remains of Pekin man in the Choukoutien cave deposits are judged to be the debris of cannibal feasts. The bones of Neanderthalers in the Krapina cave appear to have been deliberately broken, and many were charred; the female skull from Ehringsdorf shows evidence of mortal blows; the breaking of the Steinheim skull was evidently deliberate, and all the eleven Solo (Ngandong, Java) skulls have their bases and facial bones missing as if broken for extraction of their brains. The base of the Neanderthal skull found within a ring of stones on the floor of the Goat's Cave in Monte Circeo has clearly had the foramen magnum enlarged for this purpose. Therefore, it appears that head-hunting and brain-eating were characteristic of these early periods.

Mr. Miles Burkitt then dealt with "Middle and Upper Palæolithic Burials". It was not only the 'old man' of the family, but also women and children who were carefully buried. At La Chapelle aux Saints, it is true, there was only one burial of a man in a sepulchral cave, with evidence that the interment had taken place with care and ceremony; but at La Ferrassie the whole family were buried in what presumably had been their home, with care and possibly some sort of ritual, as the body of one of the children was covered by an artificially cup-marked stone. Other Mousterian burials are known. Whether the reason for this care for some of the dead was fear or love, or a belief in some sort of after-life, we can never know. The burying of implements and bones of animals with the dead would seem to suggest that the mourners thought the dead might need these at some time.

In Upper Palæolithic times we also have plenty of evidence for careful burial; and here, too, discoveries suggest that some sort of ceremony occurred at the interments. Cro-Magnon and Chancelade are sites to mention, as well as some burials at Mentone where the body of the male occurs laid out with his head on a stone pillow, and partly covered with pierced shells. The female was entirely covered with unpierced shells. In most cases ochre was sprinkled over the bodies—possibly imitating life-blood.

The practice of careful burial continued into Mesolithic times. Apart from elaborate burials, such as Ofnet (where, as Dr. Wells later mentioned, severed heads probably imply ritual head-hunting), there is plenty of evidence of simpler procedure but yet indicating careful burial—as at Hoëdic, Téviec, Nugem and Arpea.

Dr. L. H. Wells concluded the first session with a review of the pre-Neolithic evidence from Britain, and in the course of his paper described the Cheddar skeleton as the finest Upper Palæolithic cave-burial in Britain, and expressed the view that some of the skeletons from Aveline's Hole (Mendip) were definite burials. The Mesolithic population of Britain may well have been derived from Upper Palæolithic groups.

## Evidence from Living Primitive Peoples

The funerary customs of living primitive races were discussed by Dr. R. M. Berndt, Dr. Jack Goody, Mr. G. W. B. Huntingford and Mr. Hitoshi Watanabe. Dr. Berndt being abroad, his paper on "Cannibalism in the Eastern Central Highlands of New Guinea" was read by Dr. Goody. Cannibalism was described as "a most nourishing and hygienic means of disposing of the dead", the practice of which is common and not abnormal in the area described. The Eastern Highlanders of New Guinea put much emphasis on warfare, and are somewhat careless of death. Behind this attitude, however, is a belief in an after-life, in reunion with the original creative beings, and eternal residence in some kind of spirit world, or alternatively in rebirth. The newly dead are considered to have much the same needs as the living, and when they appear to their kin in dreams, it is often to ask for food, warmth or fire.

Eating human flesh is not confined to members of one sex, nor is it restricted to eating one's own kin, or members of the same district or village. Men do not hesitate to eat the flesh of a female, or women that of a male, while an enemy is eaten just as readily as a member of one's own kin. People avoided eating victims of the dysentery epidemic which followed the Second World War. Human meat is regarded primarily as food, and not eaten to absorb the power or strength of the deceased.

Dr. Goody's paper was on "Death and Social Control among the Lo Dagaa of the Gold Coast". He expressed the belief that "the conflict between the mortality of the human body and the immortality of the body politic is resolved by the belief in a future life". Only situations of rapid social change can admit scepticism in this field. Lo Dagaa beliefs include punishments meted out by the Ferryman at the River of Death to debtors, witches, thieves, and to those who have refused legitimate requests. There are also the punishments inflicted in the Land of the Dead by the high god himself. The Lo Dagaa funerals are dual, consisting of: (i) the mortuary ceremony (disposal of the body), and (ii) subsequent ceremonies (connected with eschatological beliefs). Orientation of the body differs for men and women, and childless adults have a form of burial different from those who have had children. The temporary deposit of grave-goods is known among this tribe.

Mr. G. W. B. Huntingford spoke on "Nandi Beliefs in a Future Life". In common with many other East African tribes, the Nandi of Kenya rely on the hyæna to dispose of their dead. A hyæna must not be looked in the eyes in the daytime (according to the Nandi), because the spirit of a dead person may be looking through them. Every person is believed to have a shadow-soul which dies with him, and a heart-soul which passes with the body into a hyæna and finally enters the spirit-land underground. This spirit-land is considered to contain trees, grass, hills, water, sun and moon, as in this world. The spirits are believed to have cattle and grow wheat: yet there is the incompatible belief that they live on the goods provided by the living. Grave-goods placed with the dead are removed from the tomb after one day, to be re-used by the living.

The final paper on living peoples was given b Mr. Watanabe on "Disposal of the Dead by the Ai of Japan". According to the Ainu, the dead are m in the underworld by a watch-dog; from the unde world the fire-god sends the good dead to the (upstream) village of deities, and the bad dead to the (downstream) wet underworld. The welfare of the dead depends partly on correct observance of rituals and taboos by the living, who practise them carefully, since good spirits can confer punishments and blessings on the living. The corpse is dressed in clothes which are worn inside-out (an excellent example of reversal of procedure for the dead, met with also in parts of Oceania). Food is offered first to the fire-god, then to the dead, and finally it is eaten by the mourners. After the funeral feast, the corpse is extended with head upstream. All the grave-goo are ceremonially broken to release their spirits to accompany the dead to the after-life. Both tomb and grave-goods are covered with magical twigs and plants to keep away evil spirits. Post-funerary rites are performed after the dead are considered to have reached their destination. (It is hoped that Mr. Watanabe's paper will be published in full in *The Advancement of Science*.)

## Evidence from American Archæology

Evidence from South and Central American archæology was outlined in papers by Dr. G. H. S. Bushnell and Mr. Adrian Digby. Dr. Bushnell, dealing with ancient Peru, referred to the two main traditions of burial, both dating back at least to the formative period in the first millennium B.C. The first (north coast) was of recumbent burials, at first generally flexed but sometimes extended, and later almost without exception extended. A gold plaque in the mouth is frequent, and bamboo tubes for food offerings, extending to the surface of the ground, occur but are rare. The second tradition (south coast and southern highlands) had bodies seated in a crouched posture and generally wrapped in textiles to form a bundle, which may have a false face. The richer burials in both areas were elaborate, the southern mummies being wrapped in many layers of textiles, some richly decorated. The Tiahuanaco expansion spread the southern tradition over the whole coast and it prevailed everywhere until the Spanish conquest.

There seems to have been at all times a belief in the continued being of the body or at least of the bones. In Inca times it was believed that nobles and good commoners went to a happier life with the sun, and bad commoners went to hunger and misery within the earth; but the mummies were treated with the consideration appropriate to a living person. This points to a belief in a soul apart from the mummy.

Burial and the after-life among the Maya of south-east Mexico and adjoining areas between about 100 B.C. and A.D. 900 were considered by Mr. Adrian Digby. He referred to their elaborate ceremonial centres embodying temples, courts and pyramids, in some of which burials have been found. For example, at the bottom of the pyramid below the Temple of Inscriptions at Palenque in Mexico, there was a sarcophagus decorated with the design of a tree symbolizing life and rebirth, resembling that shown springing from a wounded victim on a pre-Columbian Maya manuscript. Belief in immortality is suggested by certain practices, such as modelling the features of the dead in bitumen on the skull; deposit of red ochre with some important burials; deposit of jadeite beads, perhaps to serve as money in the after-life; and occasional ceremonial killing of vessels placed with the dead.

## Evidence from Egyptian Archæology

Dr. Margaret Murray, doyen of Egyptologists, in an address memorable for its clarity of exposition, confined her review of Egyptian funerary evidence to the prehistoric and predynastic material. The Badarian burials were single, flexed as in sleep, facing the west—the Land of the Dead. The Amratian burials were communal, contracted, and again faced the west. A few exceptions may have belonged to a special cult or been foreigners. The body was sometimes dismembered, and in certain instances the head was removed and either a pot or an ostrich egg substituted. In other instances the head was preserved on its own. Gerzean burials tended to be single, contracted, and in deep graves. Lastly, those of the Semainean culture were usually single and contracted, often in wooden coffins. The bones were sometimes disarranged and piled in square heaps. A skull cult, perhaps involving scooping out the brain, was not unknown in predynastic Egypt and continued in later times.

## Evidence from British Archæology

The remaining sessions were devoted to a consideration of the British evidence from the Neolithic period almost to the present day. Dr. H. N. Savory drew upon some recent excavations in his paper on "Communal and Separate Burial in Neolithic Britain"—a paper which covered two distinct though partly overlapping cultures between 2000 and 1500 B.C. Dealing mainly with the evidence from the south-west, he stressed the rarity of articulated corpses in long barrows, caused probably by transfer from a temporary deposit elsewhere. Deliberate breaking and rearrangement of bones suggested that fear of haunting played a part in the cult. In separate burials, solicitude for the after-life is more clearly indicated by richer grave-goods, food offerings and occasional ritual breaking of the objects rather than the bodies. The encircling wall or ditch of the round barrow defined the ceremonial precinct and may be related to 'henge' monuments, although the latter were not primarily sepulchral.

"Inhumation and Cremation in the British Bronze Age, and Related Beliefs" were handled by Mr. L. V. Grinsell against the background of the less fragmentary evidence from the Ægean, Scandinavia, Brittany and elsewhere. He gave instances of occasional substitution for grave-gifts of representations of them, and of ceremonial funerary breakings. The grave-goods we find when barrows are opened are only the more durable of those originally placed with the dead, and it is only in accidental circumstances that the perishable objects are preserved—as in the tombs of the Altai region in western Siberia, where preservation was due to freezing.

In describing "Beliefs in the After-Life in Iron Age and Roman Britain", Prof. I. A. Richmond explained how "the classical world impinged upon the prehistoric, and studied the barbarian world for its own sake while tolerating native custom within its own wide borders". This renders a separation between Iron Age and Romano-British beliefs almost unreal. Wine-filled tombs of Iron Age chieftains in East Anglia match the beliefs of Trimalchio ("Let me enjoy [the funeral wine] now!"), while Mommsen's Lingonian chief, cremated with his hunting gear, would have understood the hunting scenes on tombstones of later Pictland. Higher beliefs are reflected in Plutarch's traditions from the Western Isles or by St. Cuthbert's vision of Aidan's soul. In Roman Britain, tombstones portraying daily life reflect belief in survival of a personality thus recorded, as does the "Agricola". Cavalry tombstones of victory over barbarians have more in common with Rhineland monuments commemorating victory over death. The funeral banquet refers both to after-life and ancestor-worship. As subsidiary decoration, sphinxes and lions typify death, pine-cones immortality, vines and *amorini* the Dionysiac mysteries. The soul's journey to the Blessed Isles is suggested by Tritons or dolphins.

Disposal changed from almost universal cremation to burial, less for economic reasons than because of growing belief in individual survival. Special care for the corpse is represented by the gypsum-filled coffins at York, while the Dionysiac idea of death as sleep is evoked at Chester by the figure of a sleeping child.

Dr. H. R. E. Davidson followed with an account of the funeral customs of the Anglo-Saxons, "the first people in the British Isles whose funeral practices can be studied in the light of their literature". Archæologically, nearly all the earlier practices recur in this period: cremation, partial cremation, ritual fires, food offerings, funeral feasts, mutilation of the body, real and symbolic grave-goods, animal sacrifice, ship-funerals, etc. According to Snorre Sturlason, the higher the smoke from the pyre, the more lofty the position of the dead in heaven. There is evidence for ritual fires with inhumations as well as cremations. The body was often beheaded and may have been mutilated in other ways. Broken grave-goods occasionally occur.

The period from Anglo-Saxon times to the present day was covered by Miss Violet Alford and Mr. Grinsell. In her paper on "Dance and Song in connection with Funerary Rites", Miss Alford mentioned the continuance of *pleureuses* in the Pyrenees, Mexico, Co. Kerry and elsewhere, and referred to the 'wakes' at funerals in the British Isles. Funeral dances were usually the current regional dances—jigs and reels in Ireland, reels and country dances in Scotland. Folk memories of barrow-burials live in folk-song and ballad. Denmark shows examples of a son obtaining a magic sword from his father's barrow, and the visit of 'royal maidens' to dead men in their 'earth-house'. "The Unquiet Grave", a well-known English folk-song, recounts the visit of the dead man to his sweetheart, who is disturbing his rest by her excessive grief.

"The Survival and Recurrence of Primitive Funerary Beliefs and Customs in Recent Times" was the title of the concluding paper given by Mr. Grinsell, who directed attention to the occasional recurrence of ceremonial breaking of grave-objects at funerals in the Ægean and even in Britain; the placing of coins in the mouth or hand of the dead; and the placing of white (generally quartz) pebbles on graves. Shakespeare's reference ("Hamlet", Act V, Sc. i) to the placing of "shards, flints, and pebbles" on the grave of a suicide suggests the survival of pre-Christian practices in such instances.

---

In an earlier paper which was not actually part of the general theme, Mr. L. Biek, of the Ministry of Works Archæological Laboratory, described the development of scientific techniques for obtaining evidence from burials, including the X-ray examination of a cinerary urn and its contents; examination of bronze implements to decide whether they had passed the funeral pyre; and study of 'silhouettes' of inhumations which have otherwise vanished.

A special exhibit to illustrate some main aspects of the theme was arranged at the Bristol City Museum, the aspects chosen being the ceremonial breaking of grave-goods at funerals; food offerings to the dead; the journey to the after-life (including the part played by the Ferryman of the Dead); the location and nature of the after-life; and the various methods adopted for the treatment of the dead.

The programme was concluded by Prof. E. O. James, who in his summing up indicated the change in emphasis from 'disposal of the dead' to 'beliefs in an after-life' from Upper Palæolithic times onwards. There is much archæological and anthropological evidence for belief in human survival; but the belief in immortality tends to involve more advanced philosophical concepts.

The results of the programme were felt to be eminently satisfactory. A full or large attendance was maintained throughout, and the percentage of younger people at the sessions was larger than for some years. Of the fifteen speakers present, eight attended all the sessions, three about half, and the remaining four came mainly to deliver their own papers, either breaking their holidays or in the midst of heavy commitments. Not a few of the audience came from other sections; but the most noteworthy result was the large number of archæologists and anthropologists whose minds became enriched by hearing the papers, and this applied both to the lecturers and to members of the audience.

I am grateful to all the speakers who kindly provided summaries of their papers, which have been used (together with my own notes) in preparing this account. L. V. Grinsell

# MANCHESTER COLLEGE OF TECHNOLOGY

## GRANT OF A CHARTER

By Dr. B. V. BOWDEN

Principal

THE recent grant of a Charter to the Manchester College of Technology marks another important stage in the development of the College, which traces its history back to a Mechanics Institute founded in 1824 by eleven far-sighted Manchester business men, who each contributed £634 for the purpose. By 1905 it had acquired such a reputation at home and abroad that the University of Manchester created a Faculty of Technology which was incorporated in the College.

Thus for the past fifty years the College has discharged two quite separate and vitally important functions. It has trained full-time university students for university degrees, and it has also trained large numbers of full-time and part-time students in a variety of subjects which lead to qualifications other than degrees. This interesting association of university and non-university work will continue under the new constitution. The College will still be part of the University of Manchester, from which it derives so much of its academic strength. The standard of non-university work will be constantly raised by the elimination of the more elementary studies. Courses for Higher National Certificates will still be provided; but the most important progress in this section will be in the provision of part-time or short full-time courses of postgraduate or refresher type. By this means the developments which take place so rapidly in technology will be brought to the notice of engineers and scientists engaged in industry.

No other institution in Britain has quite the same association of university and non-university work, an association of the greatest importance in meeting the needs of industry for technologists of varied training and background.

The College has always been fortunate in the support which it has received from industry, and there are already signs that such support will be forthcoming on an even greater scale under the new regime. In return, the College will strive to serve industry by making available specialized equipment, by consultation with members of the staff on scientific and technical problems as well as by training personnel.

Situated in the heart of the most intensely industrialized area in the world, the College must play an important part in providing the increased number of highly qualified scientists and technologists essential for the national welfare. To achieve this purpose, further expansion will be necessary—expansion in enrolments, in staff and in accommodation and equipment. A start has already been made; for the session 1953–54, 670 students were following full-time university courses in the Faculty of Technology. It was then planned to double this number by 1962 and a most encouraging start was made last October, when the number of new enrolments increased by 45 per cent; there is a further increase in the present session.

New chairs in municipal engineering, applied physics, industrial administration, textile chemistry and chemical engineering have been created, and more are envisaged.

Building extensions approved in 1928 are now coming into use; these extensions were, however, planned to relieve congestion existing thirty years ago, and further space is now essential. Preliminary steps have already been taken to provide a campus for the College and to meet future needs.

From small beginnings more than a hundred and thirty years ago the College has developed to its present stature, and it is confidently expected that, with the additional prestige bestowed by the Charter, its progress in the future will be no less remarkable.

# OBITUARIES

## Dr. R. C. L. Perkins, F.R.S.

Dr. R. C. L. Perkins, the distinguished entomologist, best known for his work on the fauna of the Hawaiian Islands, died on September 29 at Bovey Tracy, Devon, at the age of eighty-eight.

Robert Cyril Layton Perkins was born on November 15, 1866, at Badminton, Gloucestershire, the second son of the Rev. Charles Mathew Perkins. He was educated at the Merchant Taylors School in London. In 1885 he won an open classical scholarship to Jesus College, Oxford; but after two years at Oxford he changed to science.

In 1891 Dr. Perkins was chosen by a committee appointed by the Royal Society and the British Association to undertake an investigation of the land fauna of the Hawaiian Islands. For nearly ten years he worked strenuously for this committee, collecting material in all parts of the Islands. In 1899 his comprehensive volumes on the insect groups and birds began to appear in the "Fauna Hawaiiensis", and continued until 1913, when he completed the general introduction to the whole series. By this time he had already received the Linnean Society's Gold Medal for 1912.

During 1902–4 he worked for the Agricultural Department of the Territory in various capacities. But in 1904 the Hawaiian Sugar Planters' Association put him in charge of the new insect department of its experimental station. His work here with O. H. Swezey and F. Muir was mainly concerned with studying and controlling the pests of sugar cane, by introducing their natural parasites from their countries of origin.

Dr. Perkins was forced to retire in 1912 through ill-health acquired in the strenuous field-work under the exacting climatic conditions of Hawaii. He settled at Newton Abbot in Devon, but continued to work on his accumulated Hawaiian collections and to write about them for more than twenty years. He also continued his studies of British insects and made outstanding contributions to our knowledge of Strepsiptera, bees, crabronid wasps and sawflies. He was elected a Fellow of the Royal Society in 1920 and in 1951 an honorary Fellow of the Royal Entomological Society of London, of which he had been an ordinary Fellow for more than fifty years.

In 1901 he married Zoe, daughter of A. T. Atkinson, superintendent of public instruction, Honolulu, Hawaiian Islands; she died in 1940, and there are three surviving sons of this marriage. In 1942 he married Mrs. Clara Senior, of Highweek, Newton Abbot, and she died in 1949. His last days were sad ones, with blindness and failing strength. His loss will be regretted by the many who felt the inspiration of his genius and who experienced the encouragement he showed to those younger and less talented than he was.

Robert B. Benson

## Mr. H. L. Kirke, C.B.E.

Mr. Harold Lister Kirke, formerly head of the Research Department and assistant chief engineer of the British Broadcasting Corporation, died in London on August 25 at the age of sixty. He served in the First World War as an officer in the Royal Fusiliers, the Signals Branch of the Royal Engineers and the Royal Corps of Signals. Later he joined the Marconi Company and was concerned with the early development of radio telephone transmitters. He was one of the small band of enthusiastic engineers who established the Writtle experimental broadcasting station in 1922, and two years later he joined the staff of the B.B.C. In 1925 he became head of the development section, which later became the Research Department of the Corporation; and in this capacity he was responsible for many of the technical advances made by the B.B.C. over the ensuing twenty-five years.

Important contributions were made by Kirke to the development of high-quality sound broadcasting at various stages from the studio through the transmitters and aerial systems to the technique of reception. Latterly, his study of the problems associated with sound broadcasting at very high frequencies was particularly valuable, and the decision of the B.B.C. to adopt the V.H.F. frequency-modulation system was based to a great extent on his research work.

Kirke was an active member of the Institution of Electrical Engineers; he was chairman of the Radio Section during 1944–45, and a member of Council from 1947 until 1950. He was also a Fellow of the Institute of Radio Engineers of New York, and was vice-president in 1952. He played a leading part in forming the Acoustics Group of the Physical Society, and was chairman of the Group in 1947. He was appointed C.B.E. in 1947.

Many of those engaged in radio research over the past quarter of a century will remember Kirke as an enthusiastic and pleasant companion at technical visits and demonstrations, and as a wise counsellor at meetings of boards and committees. It was with great sorrow that all his colleagues and associates learnt of his retirement through illness in 1952, two years after his appointment as assistant chief engineer of the B.B.C.

R. L. Smith-Rose

## Lieut.-Colonel W. French, C.B.E.

Lieut.-Colonel William French, a member of the Council of the City and Guilds of London Institute, who was superintendent of the Institute's Department of Technology during 1934–49, died on September 18. Colonel French had had a varied career in the law, in the army during the First

World War, in the civil administration in Iraq, and in the iron and steel industry, before going to technical education. He joined the "City and Guilds" in 1929 at a time when the Institute was slowly recovering from the First World War. The subsequent remarkable expansion of its work until 1939 and the resumption of expansion from 1942 were largely due to his wise guidance. His major contribution was the building up of the Institute's system of advisory committees, where representatives of industry and education together plan and keep up to date the schemes of syllabuses and examinations upon which technical education, particularly at craft level, is based both in Britain and overseas. This advisory committee system transformed a rather rigid external examining body into an instrument sufficiently flexible to meet the developing needs of industry, yet sufficiently stable to maintain the high standards for which the "City and Guilds" has always stood.

Colonel French was especially successful in his personal relationships with the officers of the Board of Education and local education authorities, technical college staffs and those in industry (then fewer in number) who saw the need for better technical education. With his love of craftsmanship, his passionate concern for the well-being of young people, his transparent honesty and his pungent humour, he unobtrusively did much between the Wars in the technical education field to dispel misunderstanding and to promote that co-operation among technical examining bodies, teachers' organizations and professional and industrial bodies which nowadays is taken for granted. During the Second World War, though hampered by ill-health, he played a useful part in discussions preceding the drafting of the 1944 Education Act and, after the War, in the negotiations that ultimately led to the formation of the Associated Examining Board.

CYRIL LLOYD

# NEWS and VIEWS

## Atoms for Peace Awards

DR. JAMES R. KILLIAN, jun., president of the Massachusetts Institute of Technology, is to be chairman of the Organization and Planning Committee of Atoms for Peace Awards. In addition to Dr. Killian, the Committee will include Dr. Detlev W. Bronk, president of the Rockefeller Institute for Medical Research and president of the National Academy of Sciences; Dr. Ralph J. Bunche, Under-Secretary General of the United Nations; Dr. Arthur H. Compton, formerly chancellor of Washington University; Mrs. Douglas Horton, formerly president of Wellesley College; Dr. Mervin J. Kelly, president of the Bell Telephone Laboratories; and Dr. Alan Waterman, director of the National Science Foundation. The Atoms for Peace Awards, it will be recalled, were established last summer as a memorial to Henry Ford and Edsel B. Ford by a Ford Motor Company Fund appropriation of 1,000,000 dollars. It will provide 100,000 dollars annually for ten years to be spent in helping to provide incentives for the world's scientists, inventors and engineers—without regard for nationality or political belief—towards finding new ways in which atomic energy can be used for the welfare of mankind. It is now announced that the Executive Committee of the Massachusetts Institute of Technology has agreed that the headquarters of the new institution be located at the Institute. In inviting Dr. Killian and the Committee to undertake the planning and organization of the Awards, Mr. Henry Ford II expressed the hope that the Committee "would set up the organization of the Awards so that the organization would be an independent corporate entity, entirely separate and divorced from Ford Motor Company".

In informing Mr. Lewis Strauss, chairman of the Atomic Energy Commission, of the establishment of the new institution on July 25, Mr. Ford described it as a response to the hope expressed by President Eisenhower at the July meeting of the "Big-Four" in Geneva that "private business and professional men throughout the world will . . . provide an incentive in finding new ways that this science can be used . . . for the benefit of mankind and not for destruction". Mr. Ford said at that time, "We would propose that when the organization of this new memorial fund is completed, the Board of Trustees of Atoms for Peace Awards appoint each year a competent International Jury of Awards for the purpose of selecting from among the world's scientists, inventors and engineers—without regard for nationality or political belief—the individual or group of individuals who, in the Jury's judgment, has made the greatest contribution during the year to peaceful uses of atomic energy; that the individual or group so selected be granted with appropriate ceremony the Atoms for Peace Award for that year; that the annual Award carry, in addition to a suitable medal to be designed and cast for the purpose, an honorarium of 75,000 dollars; that, if during any year the International Jury of Awards or the Board of Trustees finds no candidates pre-eminently meriting the Atoms for Peace Award, the sum at the disposal of the memorial fund be used that year for scholarships and fellowships most likely to contribute to the advancement of the new science of peaceful application of atomic energy".

## Massachusetts Institute of Technology: Prof. F. O. Schmitt

PROF. FRANCIS O. SCHMITT, at present head of the Department of Biology of the Massachusetts Institute of Technology, is relinquishing his post to take up the special appointment of Institute professor, and will be succeeded in the Department by Prof. Irwin W. Sizer, at present associate professor of biochemistry. The post of Institute professor is a special one designed to recognize outstanding achievement and to give its holder freedom to concentrate on research and advanced teaching; the only other person at the Massachusetts Institute of Technology who holds this rank at present is Prof. John C. Slater, the distinguished solid-state physicist. Prof. Schmitt's special field of study is in the use of the electron microscope for biological research, a field in which he became interested through his early work in X-ray diffraction and polarization optics for the study of the molecular organization of biological cells. After graduating from Washington University, St. Louis, in 1924, he did research work there, and also in Berkeley (California), London and Berlin. He became head of the Department of Zoology in Washington University and then in 1941 he went to the Massachusetts Institute of Technology, the year in which the first electron microscope for use in an academic biological laboratory was installed (now there are six such instruments in operation there). During recent years Prof. Schmitt has been working on the isolation of various protein molecules, using especially the giant nerve fibre of the squid. He is at present making studies of collagen in connexion with rheumatoid arthritis and the tanning of leather.

### Physics at Newcastle: Prof. W. E. Curtis, F.R.S.

The recent retirement of Prof. W. E. Curtis from the chair of physics at King's College (University of Durham), Newcastle upon Tyne, marks the end of a thirty-year period of considerable expansion in the Department of Physics of which he has been director. After holding the posts of lecturer in the University of Sheffield and reader in King's College, London, he went to Newcastle, to what was then Armstrong College, in 1926, as successor to Prof. Henry Stroud. He at once set himself to organize research in the Department and soon had a school of students working in his own subject of spectroscopy, to which later other branches of research were added. The teaching staff on his arrival consisted of four lecturers, a number which has been more than doubled in the ensuing years, while a reader and a professor of theoretical physics have been added to the staff. Beside directing the Department, Prof. Curtis has taken an important part in the administration of the College, being for several years sub-rector. Throughout the First World War he served in the Royal Navy, and during the Second he was in the Ministry of Home Security and then in the Armament Research Department, being superintendent of applied explosives during 1943–45. His work in spectroscopy was recognized by his election to the Royal Society in 1934, and during 1950–52 he was president of the Institute of Physics. Though he has now retired from his chair, Prof. Curtis still has a number of scientific activities, and he is at present remaining in Newcastle.

### Royal Society Antarctic Expedition

The advance party of the Royal Society International Geophysical Year Antarctic Expedition will leave Southampton on November 22 in the M.V. *Tottan* (540 tons) and will prepare the installation of a scientific research station on the Antarctic mainland, on the shores of the Weddell Sea, south of the Falkland Islands. Conditions permitting, it is hoped to set up the station in the Vahsel Bay region (78° S., 35° W.), which is one of great scientific interest for geophysical studies, and, if successful, a further party, eighteen strong, consisting mainly of scientific research workers, will sail in a year's time to relieve the advance party and complete the Royal Society's Antarctic station for the International Geophysical Year (July 1957–December 1958). The station will be one of twenty-two international geophysical stations being set up on the Antarctic mainland by British Commonwealth countries, the United States, the U.S.S.R. and other countries. The advance party will be under the command of Surgeon Lieut.-Commander D. Dalgliesh and will consist of three scientific workers—an electronic engineer from the Army, a radio-astronomer from Jodrell Bank (University of Manchester) and a meteorologist from the Meteorological Office—and six others. The pilot programme of scientific observations includes surface meteorological measurements, ionospheric research, auroral studies, measurements of atmospheric ozone and glaciological observations; among the scientific instruments will be an all-sky camera which will photograph the aurora australis. The chartering of the ship and the provision of all supplies has been done by the Falkland Islands Dependencies Survey acting through the Crown Agents, on behalf of the Royal Society. The Royal Society has been associated with Arctic and Antarctic expeditions for nearly two centuries: in 1772, in association with the Admiralty, it instructed Captain Cook to "explore the high southern latitudes with a view to determining the existence of a great antarctic continent".

### B.B.C. Colour Television Experiments

For some time past, the B.B.C. Research Department has been studying the technique of colour television, and recently a programme of experimental transmissions was started outside normal broadcasting hours. On October 20, Sir Harold Bishop, director of technical services, presented a special demonstration for the Press. This comprised the transmission over a closed circuit at the Alexandra Palace station, of still pictures, a short travel film and a number of 'live' camera shots, all of which were reproduced at the receiving end as attractive colour pictures. The technique used in this work is based on the American N.T.S.C. (National Television System Committee) adapted to the British 405-line definition and the normal bandwidth of black-and-white television in Britain. In this system, the red, green and blue components of a coloured picture are 'combined' into a pair of 'chrominance' signals, and a brightness or 'luminance' signal. The latter (luminance) signal can be made to give a compatible picture to a viewer possessing a black-and-white receiver; and the most important purpose of the present series of experimental transmissions is to determine whether this compatible reception—of a black-and-white picture from colour transmissions—is satisfactory. Viewers participating in these experiments are asked to report on any differences experienced in the sound and vision reproduction as compared with the normal reception of the regular black-and-white programmes. Sir Harold Bishop said that the results of these tests would be reported to the Postmaster General's Television Advisory Committee; but he thought it unlikely that a colour television service for Britain would be ready for at least three years.

### British Museum (Natural History)

The British Museum (Natural History) has purchased a new specimen of *Scelidosaurus*, a genus which is geologically the oldest armoured dinosaur. Up till now it has been known by one almost complete but somewhat distorted skeleton, already in the Museum, collected and prepared by James Harrison a century ago, and by a few isolated bones of a young *Scelidosaurus* more recently preserved in the Lyme Regis Museum. The latest acquisition was found about a year ago by Mr. J. F. Jackson, of Charmouth, a well-known collector of fossils. He discovered a large slab of Lower Liassic limestone which, on splitting, showed the bones of the hind leg, the hip girdle, and some of the backbone; there are also indications of the young stages of the bony plates of the back.

During the past few months the Department of Entomology of the Museum has been searching along the south coast of England from Kent to the Isle of Wight for two moths, *Hydraecia hucherardi* and *Lithophane lapidea*. Apart from their rarity, the interest of these two species, which are inhabitants of central and southern Europe, is in the further evidence their occurrence in southern England provides of the gradual change of the climate of the British Isles, a change which is already well supported by botanical evidence. Many specimens of *H. hucherardi*, the larva of which burrows in the roots of the marsh mallow, have been obtained, and the principal features of its life history have been ascertained; very few *L. lapidea* have so far been collected. Other recent work of the Museum includes a collecting trip to Yugoslavia by Mr. R. L. Coe, in order to obtain Diptera, more than nine thousand specimens being collected, during which contacts were made with the staffs of various scientific institutions. Another member of the staff, Mr. P. N. Lawrence, visited the south of France, where he collected more than four thousand specimens of Collembola in the neighbourhood of the Eastern Pyrenees. A very fine series of hydroid medusae from Plymouth and elsewhere, numbering about fifteen hundred specimens, has been presented to the Museum by Mr. F. S. Russell, director of the Marine Biological Association of the United Kingdom, Plymouth, and a collection of approximately a thousand slides of foraminifera from various horizons from the Cretaceous to Recent has been presented by Miss M. A. Waller.

## The Ishihara Test and Defects in Colour Vision

An interesting article by Mr. Peter Cavanagh on "The Ishihara Test and Defects in Colour Vision" has been published in *Occupational Psychology* (29, 1; 1955). The investigation was originally undertaken for the guidance of psychologists working in the Industrial Rehabilitation Units of the Ministry of Labour and National Service during the Second World War, and the Ministry has suggested that it should be given wider circulation. It is true that many people with defective colour vision are unaware of their condition, since they see all the things that other people see and they know what colours these things are said to have. This may be fairly adequate for ordinary life; but in certain critical situations they can run into difficulties and even danger, so that it is important that people should be tested for the accuracy of their colour vision. As with all tests concerning human beings, infallibility cannot be claimed; but, used with adequate controls, the test has proved to be of great value. Mr. Cavanagh discusses the incidence and types of defective colour vision, its congenital nature, as well as its occupational implications, with a detailed study of the test, its limitations and value and the technique for reducing error.

## Council for the Preservation of Rural England: Report for 1954–55

The twenty-ninth annual report, for 1954–55, of the Council for the Preservation of Rural England (pp. 30; London, 1955) is again a fully documented account of the action taken during the year to safeguard the amenities of rural England. On town and country planning, the Council welcomed the statement of the Minister of Housing and Local Government expressing determination to stop further unrestricted sprawl of the great cities, but regrets the fact that, apart from London, no other great city has defined a formal 'Green Belt' around it. Among other matters to which the Council has given its attention are the control of unsightly advertisements, the location of a number of mineral-working sites, the position of television stations and the distribution of electricity undertakings, the conservation of Nature, the landscape treatment of roads and bridges, pollution of the air, sea and rivers, and the preservation of buildings. In a separate report published by the Sheffield and Peak District Branch of the Council (pp. 30; Sheffield, 1955), an account is given of the vigorous opposition being made to the proposed road-racing circuit in the Peak National Park. Such a circuit was approved in principle by Derbyshire County Council on May 4 without consulting the Peak Park Planning Board; this one-sided action is possible because highway authorities are not subject to planning control.

## Association of Applied Biologists: Jubilee Volume

In September last year the Association of Applied Biologists celebrated its fiftieth anniversary by a five-day session in which many distinguished biologists took part and many interesting papers were communicated. The proceedings of the jubilee meeting have now been published as Vol. 42 of the *Annals of Applied Biology* (pp. 414+8 plates. Cambridge: University Press, 1955; 25s. net). In all, some thirty-nine speeches and papers are recorded. Some of these deal with general topics such as the changing problems of applied biology, contributed by Sir John Russell, progress in plant pathology by E. C. Stakman, and the contribution of pure science to applied biology by V. B. Wigglesworth. The others relate to a variety of special topics, including the pests of crop plants and of stored products, nematodes, virus and other diseases, the use of growth-regulating substances, education and extension services, crop protection, and the forecasting and assessment of plant diseases. Detailed references to individual papers cannot be made here, but the jubilee volume may unreservedly be recommended to readers in this field as one of exceptional interest and importance.

## Sheffield Interchange Organization: Work during 1954–55

At the twenty-second annual general meeting of the Sheffield Interchange Organization, held at the Central Library, Sheffield, another firm was admitted to the Organization, bringing the total membership to forty-one, including the University, the City Library, and industrial and government research institutions. 2,649 books, periodicals and other scientific and technical papers were exchanged during 1954–55. Among the matters under consideration were the difficulties experienced by members in obtaining United States government research reports within a reasonable time, and problems encountered in tracing and consulting university dissertations which might be of interest to industrial research workers. The City Librarian was asked to approach the appropriate authorities regarding the quicker supply of American reports, and he reported correspondence with the Standing Conference of National and University Libraries, which is attempting to standardize practice and remove some of the restrictions on the freer use of theses. It was agreed that all applications for this material should be made through the City Libraries in future. It was reported that the use made of the deposit collections of British, Canadian and American atomic energy reports in the Sheffield City Science and Commerce Library is increasing. These may be borrowed by any research worker or organization in the United Kingdom, and many have been lent in this way; but an increased number have been asked for by firms in the South Yorkshire industrial area served by the City Science and Commerce Library.

## Photometric Studies of a Lunar Eclipse

A PAPER in *Publications de L'Observatoire de Genève* (Sér. *A*, Fasc. 51; 1955) on "Observation of the Total Eclipse of the Moon on January 18–19, 1954", by M. Golay, deals with the results, obtained at the Observatory of Geneva, of the lunar eclipse of January 1954. The observations were carried out with the Schaer refractor, 20 cm. aperture, and were specially directed to a photometric study around 5750 A. This region was selected because Barbier and his collaborators had suggested many years ago that the region 5750–6000 A. should be specially studied, and four photographs were taken in the band 5600–6100 A., each with an exposure of 4 min. From the results a few deductions are made, some of which will be published later. It seems that certain rays may have travelled through a considerable depth of ozone; in addition, certain discontinuities referred to are in accordance with Danjon's law on solar cycles, and it is very probable that 1954 will prove to be the minimum of solar activity.

## Welsh Folk Museum, St. Fagans: New Handbook

SUCH is the speed of development of the Welsh Folk Museum at St. Fagans that a new edition of the handbook is welcome (pp. 29. Cardiff: National Museum of Wales, 1955; 1*s*.). The attractive format is similar to that in previous issues, though visitors and others will appreciate descriptions of the recently re-erected Stryt Lydan barn, the Esgair Moel woollen factory, the Abernodwydd and Kennixton farmhouses. It is interesting to note that three other buildings, including a Unitarian chapel dated 1777, have been accepted for re-erection. A part of the much-needed Museum block is now under construction.

## Washing of Treated Bronzes

IN the August issue of the *Museums Journal*, Mr. R. M. Organ, of the Research Laboratory of the British Museum, discusses the difficulties encountered in washing treated bronzes. These are shown to be due to the presence of corrosive agents in the untreated objects and to the effects of the reagents usually employed. Practical methods of washing and for controlling the process by measuring electrical conductivity are described.

## The Night Sky in November

NEW moon occurs on Nov. 14d. 12h. 01m., U.T., and full moon on Nov. 29d. 16h. 50m. The following conjunctions with the Moon take place: Nov. 8d. 05h., Jupiter 6° N.; Nov. 12d. 01h., Mars 6° N.; Nov. 16d. 07h., Venus 0·2° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Spica on Nov. 2d. 11h., Mercury 4·5° N.; Jupiter with Regulus on Nov. 8d. 13h., Jupiter 0·3° N.; Venus with Antares on Nov. 12d. 22h., Venus 4·1° N.; and Mars with Spica on Nov. 16d. 18h., Mars 3·2° S. Mercury rises at 5h. 10m. on November 1, which is nearly 1¾ hr. before sunrise, and may be seen for a short time in the eastern sky, stellar magnitude 0·7. Its proximity to Spica on November 2 has already been referred to. About the middle of the month, it rises an hour before sunrise and will not be easily observed; after this it draws closer to the sun, reaching superior conjunction early in December. Venus sets at about 17h. 10m. during November; its stellar magnitude remains −3·3, and the visible portion of its illuminated disk varies from 0·963 to 0·924. This decrease is just balanced by its decreased distance from the earth—from 152 to 142 million miles—in consequence of which its stellar magnitude remains unaltered. Mars rises about 4h. 20m. throughout the month. About November 9 it is a little south of θ Virginis, and its easterly movement takes it near κ Virginis at the end of the month. Its stellar magnitude varies from 2 to 1·9 owing to its distance from the earth decreasing from 232 to 216 million miles. Jupiter rises at 0h. 15m., 23h. 30m. and 22h. 40m. on November 1, 15 and 30, respectively. Its close approach on November 8 to α Leonis, which is about two magnitudes fainter than Jupiter, has been pointed out. Saturn, in conjunction on November 16, is too close to the Sun for favourable observation during the month. The Andromedid meteors appear towards the end of November, but this shower is much less prolific than it was in previous years; owing to strong moonlight, they will not be visible this year. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 9d. 03h. 23·5m., 55 Leo (*R*); Nov. 24d. 22h. 23·3m., 19 Psc. (*D*); *R* and *D* referring to reappearance and disappearance, respectively.

## Announcements

DR. J. S. CARTER, deputy chief inspector of alkali, etc., works, has been appointed chief inspector in succession to Mr. W. A. Damon, who is retiring; Mr. Damon will continue with the Ministry in an advisory capacity.

THE second World Congress on Fertility and Sterility, sponsored by the International Fertility Association, will be held in Naples during May 18–26, 1956 and will consist of twelve separate sections dealing with various topics, one of which will be on veterinary problems in animal reproduction. A general lecture will be given at the Congress by Prof. Nils Lagerlöf, of the Royal Veterinary School, Stockholm, on "Biological Aspects of Male Infertility". Those wishing to read papers must send in typed summaries by November 30 and full copies by January 31. All correspondence should be addressed to Prof. Edmundo G. Murray, Ayacucho 1375, Buenos Ayres, Argentina.

MESSRS. EDWARDS HIGH VACUUM (London), Ltd., have recently re-designed their model of the cold-cathode type of electron diffraction camera based on Prof. G. I. Finch's original design. Leaflet *E*.156/1 gives full details of the new model, which incorporates the latest vacuum valves, unions and fittings and pumping equipment, together with information concerning the electron diffraction technique and its applications.

# MARINE ORGANISMS AND BIOGEOCHEMISTRY

At the Bristol meeting of the British Association, a joint session between Sections D (Zoology), B (Chemistry) and C (Geology) was devoted to papers on the topic of "Marine Organisms and Biogeochemistry". Dr. C. F. A. Pantin, who was in the chair, stressed the value of joint meetings. It is in these borderline fields, he said, that many complex and interesting problems are found, which for a variety of reasons are generally more difficult to solve than those of the traditional scientific disciplines.

The first paper, by Dr. J. D. H. Wiseman, of the British Museum (Natural History), was on the rates of accumulation of nitrogen and calcium carbonate on the equatorial Atlantic floor. The rate of accumulation of nitrogen is, under ideal conditions, a measure of biological activity, and similarly the rate of accumulation of calcium carbonate is a measure of the productivity of those organisms which secrete calcium carbonate, provided there has been no solution subsequent to deposition. Dr. Wiseman said that geochemically it is significant to determine these rates, and to discover whether a change can be correlated with an alteration in some fundamental property in the upper layer of the sea. The investigation has been carried out on sixty sections each approximately ½ cm. thick. These were taken continuously down an equatorial Atlantic core, collected by the Swedish Deep-sea Expedition of 1947–48. Sedimentation in this core had apparently been continuous, and there was no evidence of disturbance by benthonic organisms, or through other causes.

In order to compute, from the percentages of nitrogen and calcium carbonate, rates of accumulation, it was necessary to determine the weight of dried salt-free sediment in a column of unit area through each section in its original moist condition (hereafter called weight of sediment in the section), as well as the number of years (the age) required to deposit each section. The weight of sediment in a section of known thickness can be computed from its chlorinity. The reason for this is because in highly calcareous deep-sea sediments, composed for the most part of planktonic foraminifera and a clay component, there is a relation between the weight of salt-free sediment in 1 c.c. of the moist sediment and its salt content. Age computations are, therefore, made from the weight in each section of selected elements, the rates of sedimentation of which have been shown to remain constant with time. Dr. Wiseman said that to understand the method it is necessary to appreciate the origin of the non-biological components of deep-sea sediments. The components may be divided into two classes: the hydrogenous components, and the unweathered high-temperature minerals derived from the lithosphere. Included in the hydrogenous components are the secondary minerals formed by ionic reactions in the continental hydrosphere. There are also substances precipitated in the marine hydrosphere—for example, as hydroxides—and some probably in the form of alumino-silicate sols. In addition, there are elements chemically scavenged from sea water. The high-temperature lithogenous minerals are derived from the land, as well as from submarine rocks and volcanoes. Minerals from this source are fortunately very rare in this core.

If the rate of sedimentation of any one of the components of either class changed, this would in general be reflected in a change of chemical composition. For example, if there were a sudden addition of the lithogenous mineral ilmenite, this would be shown by a change in the titanium percentage when expressed on a carbonate-free basis, as well as in the iron/titanium ratio. Dr. Wiseman then gave the theoretical reasons for constancy in the rate of sedimentation of the hydrogenous components in those areas of the deep-sea floor where there had been no superimposed complications. Changes in the rate of sedimentation of the non-biological components were found in terrigenous sediments (derived largely from the land), and in some deep-sea sediments, especially those from volcanic regions, or where there had been sediment transportation by turbidity currents. It was therefore essential, before computing age, to check from the chemical composition of each section that the rates of accumulation of the selected elements had remained constant with time, and that there had been no post-depositional chemical movement.

The percentages of iron and titanium, expressed on a carbonate-free basis, as well as the iron/titanium ratios, showed in this core no appreciable variations. From this it was concluded that there were no significant changes in the rates of accumulation or post-depositional movement of these two elements. The age of each section was computed from the iron and titanium percentages, and where there were notable percentage differences between the two results (the greatest was 12 per cent), it was possible to make an objective choice.

A graph of the rates of accumulation of calcium carbonate for each section shows that the annual rate varies between 0·9 and 1·1 mgm./cm.$^2$ during the past 7,000 years; then there is a rapid fall, and at approximately 15000 B.C. the rate is 0·28 mgm./cm.$^2$. Similarly, the annual rate of accumulation of nitrogen varies between 2·4 and 3·6 × 10$^{-4}$ mgm./cm.$^2$ during the past 7,000 years, followed by a rapid fall to 1·1 × 10$^{-4}$ mgm./cm.$^2$ at approximately 16000 B.C.

Biological examination has demonstrated that when the foraminiferal assemblage was of a warmer type, the rates of accumulation of both calcium carbonate and nitrogen were higher. This conclusion is strongly supported by the temperatures (Table 1) at which the shells of planktonic foraminifera were deposited. These temperatures are based on oxygen-18 measurements, carried out by Dr. C. Emiliani.

Dr. Wiseman concluded that, in the equatorial Atlantic Ocean about 15000 B.C., when the upper layer of the sea was about 5 deg. C. cooler, the rates of accumulation of both nitrogen and calcium carbonate were approximately a third of their present-day values.

The second paper, by Mr. M. V. Strong, of the British Petroleum Research Station, was on iron bacteria as rock-forming organisms. Mr. Strong said

Table 1

| Section No. | *P3* | *P46* | *P48* |
|---|---|---|---|
| *Globigerinoides sacculifera* | 24·3° C. | 21·2° C. | 20·1° C. |
| *Pulleniatina obliquiloculata* | 21·0 | 17·9 | 17·1 |
| *Globigerina dubia* | 19·7 | 15·0 | 13·6 |
| *Globorotalia menardii* | 18·7 | 16·8 | — |
| *Globorotalia tumida* | 15·3 | 13·6 | 13·8 |
| Annual rate of accumulation of calcium carbonate | 1·00 mgm./cm.$^2$ | 0·46 mgm./cm.$^2$ | 0·34 mgm./cm.$^2$ |
| Date of mid-point of section | A.D. 1200 | 11750 B.C. | 12800 B.C. |

that the object of his paper was to bring to the attention of microbiologists organic remains, apparently bacterial, preserved in Permian rock salts. Most of the material investigated is from a deep bore-hole at Eskdale. Some of the forms described by Mr. Strong are identical with those in lower Palæozoic rock salts of Saskatchewan. It is of considerable interest that this organic material has so far been found only in red rock salts, in which the iron is present in minute hæmatite crystals, or possibly goethite.

The organisms occur as bright red discrete aggregates, which float upwards on dissolving the salt; the most common forms being needles up to ½ mm. in length. They may be sinuous or straight, and are apparently without branches; the threads may form a network, or may be set in a fine membrane of yellowish material. Rarely the threads show a swollen termination, either cylindrical or spindle-shaped with a grooved point. They are highly resistant to heat and acids, and no internal structure has been seen.

Another common form includes fragments of membranous tissue, sometimes apparently structureless, and at other times enclosing a close mesh of threads. A third form is a cyst-like, lozenge-shaped sac of permeable membrane, enclosing liquid. The length is ½–1 mm. and the width slightly smaller. Twisted threads recalling *Gallionella* occur in the form of ribbons. Mr. Strong suggested that the deposits of hæmatite found on certain islands in the Persian Gulf may be due to the solution of salt plugs in sea water.

The third paper, on the biogeochemistry of strontium, was by Dr. H. J. H. Bowen, of the Atomic Energy Research Establishment, Harwell. Since the advent of nuclear fission, there has been considerable interest in the biological fate of strontium, as two of its isotopes are among the longer-lived fission products of uranium-235. In particular, strontium-90 constitutes the major hazard, since its half-life is approximately twenty years. The element is readily taken up by plants, and in consequence may be concentrated in the bones of animals feeding on contaminated fodder. Although strontium is widely distributed in Nature, little is known about its behaviour in living organisms, apart from the fact that it tends to follow calcium. Limited knowledge about the biological behaviour of strontium is due in part to the lack of sufficiently sensitive analytical techniques for determining small amounts of the element, as well as to chemical interference of calcium, which in biological material is always present in large amounts. Spectrometric determinations are never very precise, and can seldom determine less than $10^{-8}$ gm./ml. of the element. The method of activation analysis, developed at Harwell, is sufficiently precise to determine $10^{-7}$ gm./ml. of strontium and is a major advance in the study of the inactive element. The method is used for investigating the occurrence of strontium in rocks, plants, marine organisms and sea water.

In view of the similarity of strontium to calcium, the calcium/strontium ratio is a better index of concentration by an organism than its absolute content. For example, the ratio is 50/1 in sea water, whereas in marine algae (*Laminaria*) it is about 10/1, and in molluscan shells about 200/1. Dr. Bowen concluded from these figures that *Laminaria* prefer strontium to calcium by a factor of five, whereas molluscs reject strontium from their shells by a factor of four. The calcium/strontium ratio in sea water is remarkably small compared with the ratio in most igneous and sedimentary rocks, where it ranges from 100/1 to 1,000/1. Strontium is, therefore, an element which accumulates in the sea, whereas calcium is removed by marine organisms and, to a small extent, by chemical precipitation.

In contrast to its behaviour in marine algae, strontium is neither rejected nor accumulated by the majority of land plants. The calcium/strontium ratio in the plant is generally similar to the available ratio in the soil on which the plant grows. However, in the Bristol district, where there are deposits of celestine, the strontium content of the soil is very high, and plants from this soil reject strontium in favour of calcium. In the Avon Gorge, a locality rich in strontium, one of the rare plants, the Bristol rock cress (*Arabis stricta*), may accumulate strontium. Further work is, however, required, because the low calcium/strontium ratio may in part be due to strontium contamination on its leaves.

J. D. H. WISEMAN

# SURFACE RHEOLOGY

## ANNUAL CONFERENCE OF THE BRITISH SOCIETY OF RHEOLOGY

THE annual conference of the British Society of Rheology was held in the Washington Singer Laboratories of the University College of the South West, Exeter, during September 22–24. Dr. S. Gregg (University College, Exeter) opened the conference with a paper on the effect of adsorption on the strength of brittle solids. After summarizing the general theory of the subject, he described his recent experimental work, assisted by Dr. D. Dollimore and Dr. A. Desai, on the strength of compacted disks of compressed powders, broken *in vacuo* and in controlled atmospheres. Adsorption isotherms were prepared. The density of elastic energy located between two planes at distance $a$ apart is $\frac{1}{2} \cdot \frac{\sigma^2}{E} \cdot a$, where $\sigma$ is the stress and $E$ Young's modulus. Although, in the case of glass at the rupture point the value of $\sigma_{\max.}$ is calculated to be $10^{11}$ dyne cm.$^{-2}$, the experimentally measured value is about one-hundredth of this amount. The discrepancy is attributable to the weakening effect of the adsorption of water molecules on the surfaces of incipient cracks. The reduction in surface energy on exposure to vapour, $(\gamma_{\text{vac.}} - \gamma_{\text{vap.}})$, in relation to the amount adsorbed per gm. of solid is $\frac{RT}{SM}\int_0^p x \, d \ln p$, where $S$ is the specific surface, $p$ the pressure of adsorption and $M$ the molecular weight. Graphs relating the breaking strength of disks of compacted calcium carbonate, kaolin and boric acid powders, measured under different states of adsorption and desorption, together with derived graphs relating strength and surface energy, etc., were shown.

When benzene vapour replaced that of water in the experiments the strength of the disks remained practically unchanged, although the vapour had been strongly adsorbed with a consequent fall in surface energy. Dr. Gregg explained this anomaly as being due to the relatively large size of the benzene molecule, the ingress of the vapour into the cracks being prevented. In the discussion the meeting supported this view, and considered explanations of other anomalies found under conditions of supersaturation, and the partial absence of hysteresis with boric acid during adsorption and desorption.

In a paper on lubrication by films of solid materials, Miss E. Kay spoke on an investigation at the Royal Aircraft Establishment, Farnborough, made jointly with Mrs. E. Bielak and Dr. E. W. J. Mardles, in which a wide variety of fine powders, including metallic stearates, waxes, polytetrafluoroethylene, molybdenum sulphide, graphite, etc., dry and dispersed in liquid media, were examined under different conditions and between various bearing surfaces. Dry lubrication is often preferable both under the condition of a wide temperature-range, such as that with aircraft, −80° C. to beyond 250° C., and with light mechanisms of precision when oil seepage and creep, even of 'non-spread' oils and with use of 'epilame' barriers, tend to produce dry bearings and alteration in the inertia of fine moving parts. It was found that with a dry lubricant, although a higher coefficient of friction may be obtainable, the coefficient changes but little over a wide temperature-range. A wide scatter of results obtained with powders under some conditions is attributed to the inclusion of moisture or of oil, to failure of the surface to retain the solid lubricant and to physical changes. Considerable attention is required to find the best method of applying solids for different lubricating purposes.

Members of the meeting then discussed the effect of particle size and shape and the relative merits of dry powders and their use in oil and grease dispersions.

A. F. Latham with Dr. K. G. A. Pankhurst (British Leather Manufacturers Research Association, Egham) spoke on surface viscometry—the tanning of protein monolayers. Insoluble monolayers, spread on a water surface, may exist in a variety of states of aggregation ranging from a rigid two-dimensional 'solid' to an almost perfect surface 'gas'. Mr. Latham described the design and use of a rotational viscometer for measuring the viscous drag of these surface films and distinguishing between Newtonian and non-Newtonian flow.

Protein monolayers exhibit a wide variety of surface rheological properties according to the surface pressure. The changes are reversible and, in the case of serum albumen, can be interpreted by change from the α- to β-keratin pattern. The surface viscosity of collagen is much lower than that of serum albumen due to reduced inter-chain linkage; but, when spread on a tanning material such as mimosa tannin, the surface viscosity increases by nearly a thousandfold. Mr. Latham described how use is made of the rate of formation of cross-linking to investigate tanning reactions. In reply to queries, he spoke on results obtained with a number of substrates and on the technique used for examining various rheological properties of the monolayers.

In a paper on surface films of poly-di-methyl siloxanes on organic liquid substrates, Dr. W. H. Banks (Printing, Packaging and Allied Trades Research Association, Leatherhead) considered the spreading behaviour of a silicone fluid of average molecular weight 2,000, its surface films having the property of suppressing the foaming of oils and the mottling of paints. The special apparatus developed for the study was described, and graphs were shown relating results obtained for film pressure and film area. Hysteresis effects were observed. Lycopodium was used for observing the rate of spreading on a variety of organic liquids, which was found to be in accord with the relation $l \propto \sqrt{t/\eta}$, $l$ being distance moved, $t$ time in sec. and $\eta$ the viscosity of the substrate. The movement of the surface films caused a gradient in the substrate, a film of thickness 25 A. being sufficient to cause motion. In the discussion that followed, members considered possible mechanisms of action of silicone fluid films in suppressing foaming, mottling, evaporation and surface turbulence.

In their paper on the rheological properties of dispersions as criteria of the degree of wetting, Dr. E. W. J. Mardles (Farnborough) and Mr. A. de Waele (Gestetner, Ltd.) first pointed out the difficulties of ascertaining the degree of wetting of a solid surface by a liquid using the Young–Dupré equation modified by Harkins. Contact angles at 'equilibrium' may not exist due to the presence of adsorbed liquid films beyond the periphery of the pool, and the spreading of a liquid over a solid surface can be shown to be non-Newtonian. Although there is some correlation between heats of immersion of powders in various liquids and the rheological properties of their dispersions, numerous exceptions occur due possibly to the fact that the wetting of a surface by a liquid continues over a long period of time. Evidence of this is given by a decrease with time in the viscosity of a freshly made dispersion, by the decrease in the coefficient of friction by oil between bearings during several hours of wetting, and by electrical conductivity measurements which, in the case of a dispersion of carbon black in liquid paraffin (British Pharmacopœia), continued to change over a period of twelve months. The authors presented results in graphical form indicating the effect of adding wetting-agents on the rheological properties and conductivity of a number of suspensions. Using one powder dispersed in a variety of liquids, or several different powders dispersed singly in the same liquid, the concentration by volume being the same, the rate of aggregation of the particles (indicated by the rheological constants, by the sedimentation-rate and volume, and by conductivity tests) was found to vary considerably, the variations being related to the degree of wetting of the particles by the dispersing media.

The conference included an afternoon visit to the works of the Exeter Brick and Tile Co., Ltd., when Dr. H. H. Macey gave a talk on rheological problems connected with clays and ceramics. At the annual general meeting of the Society, Prof. J. G. Oldroyd was elected president.

E. W. J. Mardles

# INDUSTRY AND TECHNICAL EDUCATION IN GREAT BRITAIN

A CONFERENCE on "Industry and Technical Education", organized by the Regional Advisory Council for the Organization of Further Education in the East Midlands and by the North Midland Regional Council of the Federation of British Industries, was held at the College of Technology, Loughborough, on April 21, 1955, and the report of the conference has now been published*. It contains the text of the chief addresses and summaries of the discussions at the two sessions.

At the first of these sessions, which considered the relation between part-time, full-time and sandwich courses, Dr. H. L. Haslegrave, putting the point of view of the technical college, expressed the opinion that the technical college is concerned with the development of the whole man, his character and his mind, and that the best training in the application of knowledge is to use it by actually doing things. He emphasized the importance of technical colleges, as well as industry, making full use of their personnel even if it involves a policy of concentration of courses. He thought that the field for full-time courses of three to five years is restricted to branches of industry in which extensive practical training is unnecessary or in which facilities for such practical training do not yet exist. Courses for semi-skilled and skilled personnel, for technicians and for professional men should be regarded as of equal importance. Putting the point of view of the engineering industry, Air Commodore W. C. Cooper said that for the professional engineer or technologist a full appreciation of the economic factors is as essential as high standards of technical competence and knowledge. He thought, however, that there is a danger of overstressing the need for such men and women, because in the main the new knowledge must come from those who have received the equivalent of a full-time university education of at least three years, and he questioned the desirability of employing those so trained in technological applications. He did not think that the sandwich course is the ideal form of training for technical staffs, preferring an industrially based residual training in industrial colleges specifically created for the purpose.

Mr. R. B. Simpson, speaking for the textile industry, thought that, for persons fifteen years old leaving secondary modern schools, technical colleges provide the opportunities and encouragement to obtain the qualifications which employers can recognize as an accepted standard of achievement in their particular sections of the textile industry. The technical colleges also have to cater for grammar-school boys, particularly those who have failed to achieve the necessary subjects at the Ordinary level of the General Certificate of Education to enable them to go forward to a degree. For graduates, they provide the courses, possibly a sandwich course, leading to an associateship of the Textile Institute. The discussion also emphasized the importance of developing loyalties in young people, by showing them how their work helps both their companies and contributes to the welfare of the whole community, and the value of those who are technically qualified and possess the ability to get the best out of their workpeople.

The second session was concerned with the promotion of increased co-operation between industry and technical education. Mr. R. E. Wood dealt with the functions of the governing body and advisory committees of a technical college, and stressed particularly the value of part-time staff from industry. Mr. F. Stephenson, dealing with the work of local education authorities in this field, thought that the Regional Advisory Council is the most effective means for promoting increased co-operation; but he also stressed the value of adequate grants to students and of major awards for full-time students at technical colleges. Mr. J. C. McMeeking, reviewing the existing machinery for promoting co-operation, thought that, though it goes a long way towards meeting the needs, it could be improved by giving more attention to the needs of small firms and by making craft training in colleges more practical. Every effort should be made to release more teachers for periods in industry, and it is desirable to include more members from industry on governing bodies as well as to obtain the active interest of the foremen and middle-management. Conferences of technical teachers and industrialists (including foremen) would be of mutual benefit.

# ENGINEERING AND PURE SCIENCE

FOR the twenty-third Andrew Laing Lecture which he delivered on December 10, 1954, to the North East Coast Institution of Engineers and Shipbuilders, Sir Edward Appleton chose as his subject "The Partnership of Science and Engineering". That there is a natural partnership between science and engineering may be illustrated by innumerable examples, current and historic, and, in developing his theme, Sir Edward selected his illustrations from widely varied fields. His aim was, however, not so much to demonstrate the existence of this partnership as to emphasize its importance under modern conditions.

Making a clear distinction between pure science and engineering based on the principle that the aim of engineering is essentially 'constructional', Sir Edward went on to consider the differences between scientific discovery and invention. A scientific discovery, he pointed out, does not necessarily involve invention, although it will, in general, increase the area of invention, and conversely an invention is not necessarily directly associated with scientific discovery. Speaking of the essential distinctive quality of invention, Sir Edward said that the inventive step must contain more than deductive reasoning. "Indeed," he remarked, "my own view is that the impact of an invention on the minds of others skilled in the art, should engender surprise."

The development of engineering as an art has from its early beginnings stimulated inventions and discoveries which can properly be classed in the field of pure science, and likewise advances in scientific knowledge have been turned to account in the practice of engineering. As a notable example of collaboration between the engineer and the pure scientist, Sir Edward referred to the development of vacuum technique during and subsequent to the First World War. Before the First World War the gas pressure in electric lamp bulbs was of the order of $10^{-3}$ mm. of mercury, while at the present day the residual gas pressure in certain valves can be as low as $10^{-8}$ mm. of mercury. It is largely as a result of these improvements in vacuum technique and their influence on the 'longevity' of thermionic valves that projects such as that of trans-Atlantic telephone cables have become practicable. In the submerged repeaters of the present trans-Atlantic cable, there are some three hundred valves, and the success of the scheme depends upon these valves having lives of the order of twenty years. The development of the thermionic valve has provided the technical basis for the building up of an entirely new subject, namely, that of electronics.

The release, in useful form, of the energy of nuclear fission is, of course, the supremely important new application of physical science in the field of engineering. After describing the basic phenomena of the disruption of the uranium-235 nucleus and mentioning that the first self-sustaining pile generating heat by a nuclear fission chain was set up by Fermi in Chicago in 1942, Sir Edward stated that, in the nuclear energy station at present under construction in Cumberland, the reactor temperature would be maintained at about 400° C. and that carbon dioxide gas under pressure would transfer heat from the uranium-graphite core to steam-raising equipment which would operate electrical generating equipment of normal type. Because of the temperature limitation in the reactor, however, it is unlikely that the overall efficiency of this station will exceed 25 per cent. Sir Edward went on to mention the principles of the 'breeder pile' and the problems associated with it. He then remarked: "You will have seen that the subject is now so far developed that much of the work is out of the hands of the physicist working alone. But I do want to stress that our nuclear engineer will be dealing with problems which, as an engineer—be he civil, mechanical or electrical—he will never have encountered before. Materials will have to take on for him an entirely new meaning." There would be problems associated with materials hitherto unfamiliar in engineering practice, important because of their neutron-absorbing properties, together with exceedingly important metallurgical questions concerned with the development of materials for use at temperatures much higher than those which had been common in the past. "It seems to me," he went on, "that our interest in the nuclear energy field should be one of intense preoccupation. I see, ahead, the development of an enormous industry based on technology—the industry of not only supplying ourselves with nuclear electricity generating stations, but of supplying other countries with them and possibly selling them fissile materials which we have ourselves produced from fertile uranium or thorium."

Remarking that his examples had so far been drawn from the realm of physics and engineering, Sir Edward turned to several instances of the co-operation of the chemist and the engineer. He took first that of the extraction of germanium from flue dust. This metal, which is now of immense importance as a semiconductor for the manufacture of diodes and triodes for the electronics industry, may be present in a proportion of the order of 0·5–1·0 per cent in flue dust. A novel metallurgical treatment has been developed which is much more successful in extracting the metal from certain dusts than the ordinary acid treatment. Sir Edward then mentioned some of the problems associated with the manufacture of titanium and zirconium, the use of sodium benzoate as a corrosion inhibitor and finally, as an example of existing technological development facilitating the work of the pure scientist, the application of the technique of distillation to such laboratory processes as the fractionation of isotopes.

In his concluding remarks, Sir Edward referred to the importance of the development of automatic methods in the manufacturing industry. This is a revolutionary development which will call for statesmanship on the part of both management and labour. He also spoke with approval of the policy of the Atomic Energy Authority in respect of regarding industrial firms as the appropriate bodies to carry out the design as well as the construction of nuclear power plants. He regarded it as essential that nuclear scientific and engineering knowledge should be available to manufacturing firms. The close and effective partnership of science and engineering is, in his opinion, something which is absolutely vital to the economic progress of Great Britain.

# NATIONAL PHYSICAL LABORATORY NOTES ON APPLIED SCIENCE

THE latest publications in the series "Notes on Applied Science" of the National Physical Laboratory, Teddington*, illustrate the wide range of investigations undertaken by the Laboratory, since all three are based on actual experience at the Laboratory. No. 10 in the series, "Noise Measurement Techniques", deals with the measurement of noise, defined as "any sound which is undesired by the recipient"; and is intended to act as a guide to the choice of methods and techniques suitable for the measurement of the physical characteristics of noise in varying circumstances. In two introductory sections, the general, physical and subjective characteristics of noise and the principles of broad-band and narrow-band analysis are discussed, and the remainder of the booklet is devoted to a detailed description of noise-measuring equipment, its operation and calibration. Microphones, pre-amplifiers, output meters, recorders and analysers are given full and adequate treatment, and the booklet concludes with a brief, illustrated, account of the Mobile Acoustical Laboratory at Teddington.

The second booklet, No. 11, is concerned with wind effects on bridges and other flexible structures, and is based on wind-tunnel research carried out in the Aerodynamics Division of the Laboratory, where extensive investigations have been made recently on the oscillatory effects of winds on models of two proposed suspension bridges—the Severn Bridge between Beachley and Aust, and the Runcorn–Widnes Bridge over the River Mersey. Most of the booklet is devoted to oscillatory effects although brief reference is made also to static wind loads; while bridges are the primary concern of the booklet, much of the content is also applicable to other flexible structures, such as tall chimney stacks, transmission lines and buildings. It is emphasized that an examination of the history of bridge failures reveals that a bridge ails because of both static action of wind (that is, a tendency to give the bridge a steady deflexion) and dynamic action (that is, a tendency to set the bridge oscillating), and that, in addition, the dynamic effects can occur in two ways, termed aerodynamic instability and buffeting. The experimental methods to investigate static action, aerodynamic instability, and buffeting on bridges are described in detail and the necessary equipment and the models used at the Laboratory are illustrated.

---

* National Physical Laboratory: Notes on Applied Science. No. 10: Noise Measurement Techniques. Pp. iv+40+8 plates; 2s. net. No. 11: Wind Effects on Bridges and other Flexible Structures. Pp. iv+14+7 plates; 1s. 6d. net. No. 12: Calibration of Temperature-measuring Instruments. Pp. iv+47+2 plates; 2s. net. (London: H.M.S.O., 1955.)

The third booklet, No. 12, entitled "Calibration of Temperature-Measuring Instruments", refers to a different but important section of the National Physical Laboratory's work, namely, the maintenance of standards, and in this particular case to the basic scales of temperature and the instrumental means by which they are realized. It is the most up-to-date text on the subject, and should receive the widest possible circulation. It sets forth clearly what is meant by a temperature scale, and draws a careful distinction between accuracy and reproducibility in temperature measurement, quoting as an example that the sulphur boiling point, defined as 444·600° C., may be reproduced with the platinum-resistance thermometer to about 0·005 deg. C., but its value by gas-thermometer observation is not known to better than ±0·1 deg. C. The various arrangements for the realization of the primary fixed points, including the triple point of water, and the necessary precautions to be taken, are described in detail, in addition to the primary standard and working standard instruments used at the Laboratory. One section is devoted to a description of the methods used for the routine testing of temperature-measuring instruments, and another to the baths and furnaces used in comparison tests with standard instruments; in an appendix, the definition of the 1948 International Temperature Scale is reproduced.

# METABOLISM OF PROPIONIC ACID IN ANIMAL TISSUES

By Dr. MARTIN FLAVIN[*], PRISCILLA J. ORTIZ and Prof. SEVERO OCHOA

Department of Biochemistry, New York University College of Medicine, New York

ANIMAL tissues can oxidize propionic acid; but the mechanism of this oxidation has long remained obscure. Some workers believe that this fatty acid undergoes α-oxidation to yield acrylic, lactic and pyruvic acid[1–3], the latter being oxidized to carbon dioxide and water via the citric acid cycle. However, experiments on the distribution of carbon-14 from labelled propionate in tissue glycogen[4] and acetyl groups[5], or in lactate[6], indicated the occurrence of a symmetrical intermediate between propionate and pyruvate, such as would be formed if propionate or acrylate were first carboxylated to succinate or fumarate, followed by oxidation of the dicarboxylic acid through the citric acid cycle. This possibility appeared to be strengthened by the finding of bacterial enzymes which catalyse the reverse reaction, that is, the decarboxylation of succinate via succinyl coenzyme A, to propionate[7]. More recently, an adenosine triphosphate-dependent conversion of propionate to succinate by fixation of carbon dioxide has, in fact, been reported to occur in liver extracts[8].

## Biosynthesis of Methylmalonate

We have found that dialysed extracts and ammonium sulphate fractions of pig heart, supplemented with propionyl coenzyme A, adenosine triphosphate and magnesium ions, fix carbon-14 dioxide to form a compound easily hydrolysed by alkali to yield carboxyl-labelled methylmalonic (*iso*succinic) acid[9]. The latter has been identified by (*a*) paper chromatography and autoradiography, (*b*) recrystallization with carrier, and (*c*) recovery of radioactivity in a derivative, C-methylbarbituric acid, or in propionic acid and carbon dioxide following decomposition at 150°. Under optimal conditions for the synthesis of methylmalonate, no succinate is formed by the pig heart preparations. The conversion of propionate to methylmalonate has been independently observed by Katz and Chaikoff[10] in rat liver slices.

The requirements for methylmalonate synthesis are shown in Table 1. It may also be seen in the table that propionyl coenzyme A can be replaced, although less effectively, by a mixture of propionate and coenzyme A. Under these conditions, propionyl coenzyme A is undoubtedly formed through reaction 1, catalysed by the acetate activating enzyme[11,12], which is also active with propionate.

$$\text{Propionate} + \text{CoA} + \text{ATP} \rightleftharpoons \text{Propionyl CoA} + \text{AMP} + \text{PP} \quad (1)$$

Little or no fixation (or exchange) of carbon-14 dioxide was observed with acrylyl or succinyl coenzyme A in place of propionyl coenzyme A, or with succinate or

Table 1. REQUIREMENTS FOR ENZYMATIC SYNTHESIS OF METHYLMALONATE FROM CARBON-14 DIOXIDE AND PROPIONYL COENZYME A

* Results from several experiments.

† Consisting of following components (in μmoles): tris(hydroxymethyl) aminomethane buffer, pH 7·0, 50; magnesium chloride, 2; reduced glutathione, 5; adenosine triphosphate, 2; propionyl coenzyme A, 1; potassium bicarbonate-$^{14}$C, 10; pig heart extract with 5 mgm. protein. Volume, 1·0 ml. Other additions, each 1 μmole except succinyl coenzyme A, 2 μmoles. Coenzyme A added in the last four experiments. Incubation 60 min. at 25°. Heart and other extracts prepared by homogenizing fresh tissue in a Waring blendor with 4 volumes of 0·05 *M* potassium phosphate buffer, pH 7·4, containing 0·2 *M* potassium chloride, and centrifuging 15 min. at 25,000 *g*. Supernatant dialysed overnight against 0·02 *M* potassium phosphate buffer, pH 7·0, containing 0·001 *M* neutralized L-cysteine. All operations carried out at 3–4°. Fractions obtained from the extracts by precipitation with ammonium sulphate between 30 and 50 per cent saturation, and dialysed as above, have also been used.

methylmalonate plus coenzyme A in place of propionate and coenzyme A.

The requirement of adenosine triphosphate for the synthesis of methylmalonate from propionyl coenzyme A and carbon dioxide indicates that phosphate bond energy is utilized in this reaction and recalls the results of Bachhawat *et al.*[13] with a possibly analogous reaction, the carboxylation of β-hydroxy*iso*valeryl coenzyme A to β-hydroxy-β-methylglutaryl coenzyme A.

As already mentioned, the immediate product of the adenosine triphosphate-dependent carboxylation of propionyl coenzyme A in pig heart extracts is not free methylmalonic acid but an activated form of this compound. Thus, on addition of hydroxylamine at the end of incubation for an hour of pig heart extract with coenzyme A, adenosine triphosphate, magnesium ions, propionate and carbon-14 dioxide, about 80 per cent of the carbon-14 dioxide fixed in non-volatile compounds can be recovered in the methylmalonmonohydroxamic acid area of paper chromatograms, and 20 per cent in free methylmalonic acid. Control experiments excluded the possibility that free methylmalonic acid is formed first and activated afterwards. Similar results are obtained when hydroxylamine is present throughout the incubation, except that, in this case, there is formation of unlabelled propionhydroxamic acid besides labelled methylmalonmonohydroxamic and methylmalonic acids. Whether or not any diactivated methylmalonate is formed during the incubation cannot yet be stated.

## Isomerization of Methylmalonate

In contrast to the pig heart preparations, dialysed extracts of rat heart, liver or kidney, or of sheep kidney, with little or no succinoxidase activity, form both carboxyl-labelled methylmalonic and succinic acids (or labile derivatives thereof) from propionyl coenzyme A and carbon-14 dioxide, in the presence of adenosine triphosphate and magnesium ions. Succinate was identified by paper chromatography followed by autoradiography, and by recrystallization with carrier. It can be readily differentiated from methylmalonate by heating with acid permanganate—a treatment which quantitatively destroys methylmalonate but does not affect succinate.

These results suggested to us the possibility of an enzyme-catalysed interconversion of methylmalonate and succinate, a hypothesis that was quickly shown to be correct by the finding that methylmalonate-1-$^{14}$C is largely converted to succinate (or a labile derivative thereof) on incubation with the above dialysed liver or kidney (but not pig heart) extracts[9]. In fact, this isomerization is usually the only reaction which methylmalonate can be shown to undergo in the crude extracts. Under some, as yet poorly identified, conditions, 5–10 per cent of the radioactivity of carboxyl-labelled methylmalonate can also be recovered as carbon-14 dioxide, presumably due to a more or less direct decarboxylation, rather than to oxidation of succinate. As shown in Table 2, the conversion of methylmalonate to succinate requires coenzyme A and adenosine triphosphate, and is markedly increased by the presence of magnesium ions. These requirements suggest activation of methylmalonate to methylmalonyl coenzyme A as a preliminary step for isomerization. It should also be noticed (Table 2) that the reaction is inhibited by malonate. Experiments to ascertain whether succinate can be converted to methylmalonate have so far given negative results, but further work will be required to decide whether the primary isomerization reaction is reversible.

Table 2. REQUIREMENTS FOR ENZYMATIC CONVERSION OF $^{14}$C-METHYLMALONATE TO SUCCINATE

| Components | Carbon-14 appearing as succinate (per cent) |
|---|---|
| Complete system* | 81 |
| No enzyme | 0 |
| No adenosine triphosphate | 0 |
| No coenzyme A | 10 |
| No magnesium chloride | 25 |
| Complete system with 0·005 *M* malonate | 0 |

* Consisting of following components (in µmoles): glycine buffer pH 9·0, 100; magnesium chloride, 10; reduced glutathione, 8; adenosine triphosphate, 8; coenzyme A, 1; methylmalonate-1-$^{14}$C 0·5; potassium bicarbonate, 10; rat liver extract with 15 mgm protein. Volume, 1·0 ml. Incubation, 60 min. at 25°.

When carboxyl-labelled methylmalonate is converted enzymatically to labelled succinate, the radioactivity of the latter does not seem to be *significantly* decreased by the presence of large pools of potassium bicarbonate, propionate or propionyl coenzyme A in the reaction mixture (Table 3)[9]. Since methylmalonic acid might react as an asymmetric compound on enzymatic isomerization, carboxyl-labelled methylmalonic acid was prepared in two different ways by incubation of pig heart extracts, in the presence of coenzyme A, adenosine triphosphate and magnesium ions, either with carbon-14 dioxide and propionate or with carbon dioxide and propionate-1-$^{14}$C. Both preparations were used, separately, in the experiments of Tables 2 and 3. Similar results with methyl-labelled $^{14}$C-methylmalonate (prepared by Dr. H. Castro in this laboratory) provide further evidence that the isomerization reaction involves the conversion of the whole carbon skeleton of methylmalonate to succinate. These results appear to rule out not only a decarboxylation of methylmalonate to carbon dioxide and propionate or propionyl coenzyme A, followed by recarboxylation to succinate, but also the intermediary formation of a carboxymethylmalonate derivative followed by the loss of one of the labelled carboxyls, since both carboxyl groups of methylmalonate are retained in the succinate formed. The elimination of a possible tricarboxylic intermediate is of particular interest, since the formation of such a compound might otherwise account for the apparent stimulation of the isomerization reaction by the bicarbonate ion ($HCO_3^-$) (Table 3). Purification of the isomerizing enzyme or enzyme system may throw light on the mechanism of this novel reaction, as yet without precedent in biochemistry. It is of interest to note that although methylmalonic acid was isolated twenty years ago from the urine of normal rats by Boyland and Levi[14], and has been found in the urine more recently in other labor-

Table 3. CONVERSION OF $^{14}$C-METHYLMALONATE TO SUCCINATE IN PRESENCE OF BICARBONATE, PROPIONATE AND PROPIONYL COENZYME A

| Additions to complete system* | Carbon-14 appearing as succinate (per cent) |
|---|---|
| None | 75 |
| Potassium bicarbonate (30 µmoles) | 100 |
| Potassium bicarbonate (30 µmoles) and propionate (5 µmoles) | 97 |
| Propionyl coenzyme A (3 µmoles) | 64 |

* Complete system and incubation as in Table 2, except that only trace amounts of methylmalonate-1-$^{14}$C were used.

tories[15,16], there had been no other indications that his compound might be a metabolite in the mamnalian organism.

As might be expected from the inhibitory effect of nalonate on the isomerization reaction (Table 2), in he presence of malonate relatively less succinate and nore methylmalonate are formed by liver extracts, rom propionyl coenzyme A and carbon-14 dioxide, han in the absence of malonate (Fig. 1). This result uggests that an activated methylmalonate may be n actual intermediate in the conversion of propionate to succinate; but an alternative interpretation, namely, that methylmalonate may be converted to succinate through some common precursor of the two dicarboxylic acids, has not been excluded. The hypothetical common precursor could not, however, be in isotopic equilibrium with carbon dioxide, propionate, or propionyl coenzyme A.

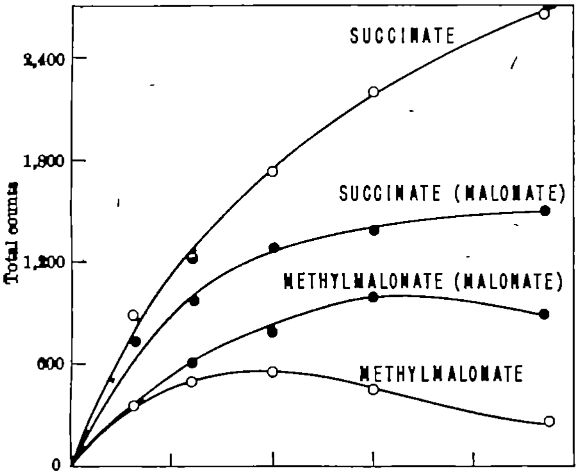

Fig. 1. Formation of methylmalonate and succinate by liver extracts, in the presence of carbon-14 dioxide, propionyl coenzyme A and adenosine triphosphate, and the effect of malonate. One of the reaction mixtures contained (in μmoles), tris(hydroxymethyl)aminomethane buffer, *p*H 7·0, 750; magnesium chloride, 70; reduced glutathione, 50; adenosine triphosphate, 75; propionyl coenzyme A, 3·5; potassium bicarbonate-$^{14}$C, 70; extract of rat liver acetone powder with 250 mgm. protein. Volume, 11 ml. The other reaction mixture contained 0·01 mole malonate besides the above components. Incubation at 25°

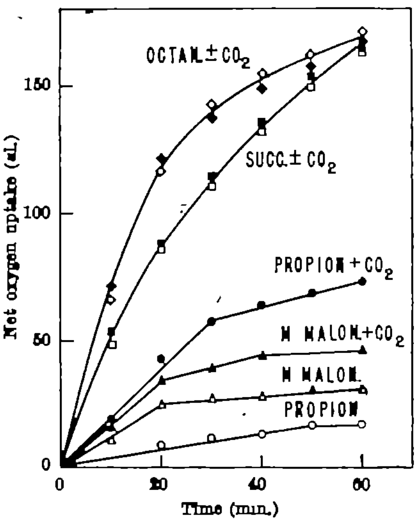

Fig. 2. Oxidation of propionate, methylmalonate, succinate, and octanoate by rat liver homogenates. Each Warburg flask contained (in μmoles), potassium phosphate buffer, *p*H 7·4, 90; potassium chloride, 150; magnesium sulphate, 15; adenosine triphosphate, 3; cytochrome *c*, 0·004; substrate (potassium salts), 3; enzyme suspension, 1·5 ml. Volume, 3·0 ml. Gas, air; temperature, 30°. Alkali-soaked filter paper in centre well. Two flasks were run with each substrate, one containing, in addition to the above components, 20 μmoles potassium bicarbonate, the other 35 μmoles tris(hydroxymethyl)aminomethane buffer, *p*H 8·3. The final *p*H in all flasks was about the same, around *p*H 7·6. The oxygen uptake in the absence of added substrate (about 20 μl. in 60 min. in all cases) was subtracted. Enzyme suspension prepared by homogenizing the livers of 24-hr. fasted rats with 2 vol. of ice-cold 0·013 *M* phosphate buffer, *p*H 7·8, containing 0·013 *M* potassium chloride, in a Potter–Elvehjem homogenizer. The suspension was mixed with an equal volume of the same solution and the mixture centrifuged at 2,200 *g* and 0° for 3 min. The sediment was taken up in a volume of phosphate–potassium chloride equal to that of the diluted homogenate, the mixture centrifuged and the sediment resuspended once more as above

## Oxidation of Propionate and Methylmalonate

Experiments with rat liver homogenates (Fig. 2) show that oxidation of propionate is markedly dependent on the presence of bicarbonate ions, whereas that of methylmalonate, although stimulated by bicarbonate ions, is not so dependent. On the other hand, the oxidation of succinate and octanoate by the same preparations is not affected by the presence of bicarbonate ions. The homogenates were prepared as described by Lehninger and Kennedy[17]. Since methylmalonate is oxidized, this compound (or, more likely, an activated derivative) could be an intermediate in propionate oxidation. Stimulation by bicarbonate ions of methylmalonate oxidation may be related to the above-mentioned stimulation of the isomerization reaction. Carbon dioxide-free water as well as carbon dioxide-free solutions of the various reagents were used for the experiments of Fig. 2. In addition, the *p*H of the reaction mixtures with no added bicarbonate was adjusted to a value close to the value of those with added bicarbonate, so that the observed results are due to the bicarbonate ion, and not to the effect of increased *p*H.

The above results indicate that, in liver homogenates, propionate is oxidized exclusively through a pathway involving preliminary carboxylation. The same conclusion has recently been reached by Wolfe[18], whose experiments with rabbit liver homogenates clearly exclude α-oxidation of propionate via lactate, and demonstrate its oxidation through succinate. Thus, the conclusions of Huenneckens *et al.*[8] and Mahler and Huenneckens[9] are not borne out by the more recent work.

The pathway of propionate and methylmalonate oxidation in animal tissues suggested by our experimental results is shown by the sequence below:

$$\begin{tikzcd}
\text{Propionate} \arrow[r, "\text{(CoA, ATP)}"] & \text{Propionyl CoA} \arrow[d, "\text{(CoA, ATP)}"] & \\
\text{(Succinyl CoA ?)} \arrow[d] & \text{Methylmalonyl CoA} \arrow[l, "?"'] & \text{Methylmalonate} \arrow[l, "\text{(CoA, ATP)}"'] \\
\text{Succinate} \arrow[r, "O_2"] & CO_2 + H_2O &
\end{tikzcd}$$

The fact that the oxidation of methylmalonate is slower than that of propionate (Fig. 2) does not exclude this scheme, since activation must precede oxidation of these compounds and may limit to different degrees the rates of oxidation of the free acids. In separate experiments with the rat liver homogenates, where the activation of propionate, methylmalonate and octanoate by adenosine triphosphate and coenzyme A was followed through the formation of hydroxamic acid, it was found that the activation of methylmalonate was very slow, that of propionate was about four times faster, and that of octanoate seven times faster than that of propionate. While octanoate is activated by a fatty-acid activating enzyme[19], through a reaction analogous to (1), the nature of the enzyme catalysing the activation of methylmalonate is unknown. Methylmalonate is not activated by the phosphorylating enzyme of Kaufman *et al.*[20], which catalyses the reversible formation of succinyl coenzyme A, adenosine diphosphate and orthophosphate, from succinate, coenzyme A and adenosine triphosphate. Likewise, there is no transfer of coenzyme A from acetoacetyl coenzyme A to methylmalonate in the presence of highly purified coenzyme A transferase[21], which catalyses the reversible transfer of coenzyme A from acetoacetyl coenzyme A to succinate. While the product of carboxylation of propionyl coenzyme A might be methylmalonyl coenzyme A, which could then undergo isomerization, it is not known whether the immediate product of the isomerization reaction is succinyl coenzyme A, some other form of activated succinate, or succinate itself. Furthermore, as already mentioned, the results so far obtained do not exclude a common precursor of both methylmalonate and succinate as the immediate product of the carboxylation reaction. The separation and purification of the enzymes involved may help to decide these questions.

A full account of this work, which was aided by grants from the National Institute of Arthritis and Metabolic Diseases (Grant *A*-529) of the National Institutes of Health, United States Public Health Service, the American Cancer Society (recommended by the Committee on Growth, National Research Council), the Rockefeller Foundation, and by a contract (*N6onr* 279, *T. O.* 6) between the Office of Naval Research and New York University College of Medicine, will be published elsewhere.

# METALLIC TRANSFER IN DRILLING AND ITS SIGNIFICANCE IN ORTHOPÆDIC SURGERY

By Dr. F. P. BOWDEN, F.R.S., and J. B. P. WILLIAMSON

Research Laboratory for the Physics and Chemistry of Surfaces, Department of Physical Chemistry, Cambridge

AND

P. G. LAING

The Children's Hospital, Pittsburgh, Pennsylvania

It is common practice in modern surgery to insert pieces of metal into the body in order to strengthen or replace a damaged bone. As these are often left in place for considerable periods, it is clearly essential that they should be inert in tissues, and interfere as little as possible with repair and normal physiology. Body tissues are corrosive to most metals, and orthopædic surgeons take great care, therefore, that all the plates, screws and bolts which are to be left in a patient are of the same material and are made of metal which has a very high corrosion resistance[1]. It is well known that corrosion may be influenced by many factors. For example, mechanical deformation of the surface, differential aeration, fretting corrosion, and changes in the *p*H value of the medium all have marked effects. The relative importance of these different phenomena has been discussed by a number of workers (see, for example, Evans[2]).

In earlier communications[3,4], attention has been directed to a further factor which should be considered, namely, the nature and composition of the metal tools used to manipulate the screws, bolts and plates. It was demonstrated by a radioactive-tracer technique that it is almost impossible to insert a screw or bolt without appreciable amounts of the tool becoming plucked out and transferred to the inserted metal. Small fragments of the tool become attached to the surface of the orthopædic appliance and are buried with it in the body. It has been pointed out that although these amounts are very small (about 10–100 μgm.) the adherent particles may form corrosion centres on the surface of the buried metal. This could cause metal ions to pass into the surrounding tissue and produce a reaction which may interfere with normal physiology. Photomicrographic examination of the tissue surrounding those parts of buried metal which had been handled heavily with tools during insertion has demonstrated that such a reaction does in fact occur, even though there may be no evidence of gross corrosion.

Recent experiments have indicated that, in orthopædic operations involving the drilling of pilot-holes

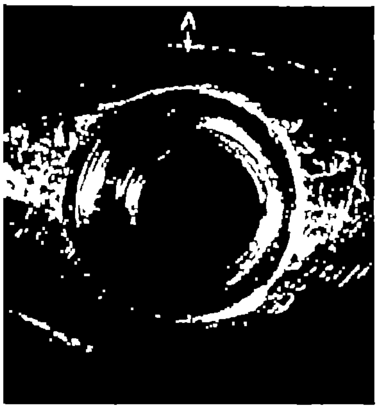

Fig. 1

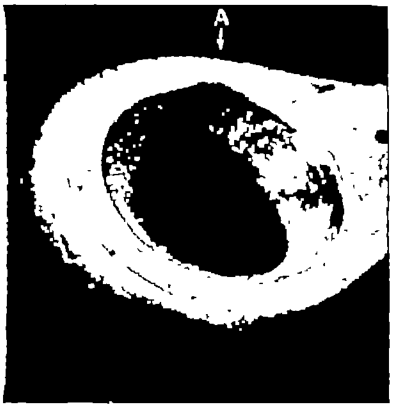

Fig. 2

Fig. 1. Hole in orthopædic plate removed from patient because of persistent sepsis; the drill had rubbed against the metal at *A*

Fig. 2. Hole in orthopædic plate; the drill has rubbed against the metal at *A*. Metal transferred from the drill to the plate at *A* may be as much as 2 mgm.

in bone the amounts of metal transferred may be very much greater than that occurring during screwing and bolting. It is usual to prepare pilot-holes in the bone to receive the screws which secure an orthopædic plate. A countersunk hole already exists in the plate, since this is prepared during its manufacture. Either engineers' twist-drills or special stainless-steel drills are commonly used for preparing the bone. Frequently such holes are drilled after a plate has already been fixed in place by two or more screws; the remaining holes of the plate are used to guide the twist-drill. Owing to the convex and wet surface of the bone, it sometimes happens that the twist-drill comes into contact with the edges of the plate-hole, and considerable friction may occur between them. Often it is desirable to insert a screw obliquely into the bone: if the pilot-hole in the bone is drilled through a plate-hole, the resulting friction may be severe. Fig. 1 shows a typical hole in an orthopædic plate which was removed because of persistent sepsis after being attached to the right tibia of a patient for five months. It is clear that the twist-drill has ground away the rim of the hole at *A*.

The transfer of metal to a plate when a pilot-hole is drilled has been measured. In the first experiment, the drills were merely allowed to touch the edges of the plates occasionally during the drilling process; in the second, oblique holes were drilled and the shoulders of the plate-holes were deliberately ground away until the damage appeared similar to that occasionally observed in plates removed from patients. Fig. 2 shows a typical experimental plate drilled in this way (compare Figs. 1 and 2).

Table 1. TRANSFER FROM TWIST-DRILL TO PLATE DURING DRILLING OF PILOT-HOLE FOR SCREW
(in micrograms)

| | Stainless steel plate | | Vitallium plate | |
|---|---|---|---|---|
| | Engineers' drill | Stainless steel drill | Engineers' drill | Stainless steel drill |
| Drill passing freely through hole in plate, touching it occasionally | 2·3 | 18 | 0·55 | 1·8 |
| Drill allowed to grind against edge of plate-hole | 3·0 | 1,500 | 1·2 | 2,000 |

HARDNESS OF THE METALS
(Diamond pyramid hardness in kgm./mm.$^2$)

| | |
|---|---|
| Stainless steel drill | 400 |
| Engineers' drill | 860 |
| Stainless steel plates | 300–350 |
| Vitallium plates | 400 |

Table 1 shows typical amounts measured when both stainless steel and engineers' drills were used to make pilot-holes in bone through stainless steel and vitallium plates. The hardness of these metals are also given. The extremely large amounts of transfer observed with stainless steel twist-drills are probably due to the fact that the plates are as hard as the drills. When engineers' drills are used, the corresponding increase in the amount of transfer is much smaller; however, these drills are more liable to break off in the bone, thus increasing the difficulty of the operation.

It is clear that the amount of transfer occurring from the drill to the plate when a pilot-hole is drilled into bone through a plate-hole can be large: it is very much greater than that observed in screwing or bolting operations. If the twist-drill is allowed to rub against the side of the plate-hole while the pilot-hole is being drilled, the transfer can be as much as 1 or 2 mgm. The surfaces of the shoulder of the plate-hole and of the screw neck are particularly vulnerable to the onset of corrosion, for when the screw-head is seated in a countersunk hole any corrosion pores which may develop in the oxide layer will not readily be sealed by dissolved oxygen carried to the site; the close fitting of the screw-head and the countersink does not permit easy access of oxygen to these surfaces. These very large amounts of transfer, together with the subsequent differential aeration of the region, may be a cause of the gross corrosion which is occasionally observed at such points[5]. The danger of this could be diminished if drill-sleeves were used when drilling through plate-holes. Other experiments show that the amount of metal transferred from the drill to the bone itself is small.

Earlier work has shown that tiny adherent fragments of foreign metal may exert a profound influence on the surface properties of the metal to which they are attached. While they are not the only cause of the corrosion of orthopædic components, they may nevertheless be an important one and merit careful consideration. These recent observations suggest that such metallic transfer may occur in particularly large amounts when pilot-holes are drilled. The properties of the buried metal are not the only points to be considered. Attention should be given to the particular combination of the tools and the metal used, and also to the care with which the tools are handled. A full account of these investigations will appear shortly[6].

We thank Colonel J. Hickman, Department of Veterinary Clinical Studies, Cambridge, for help, and the Royal Society for a grant for equipment.

## Modification of X-Ray Sensitivity of Bean Roots by Hydrogen Gas

THE presence of molecular hydrogen during irradiation is known to affect radiation chemical reactions. Its influence is ascribed to the reaction $H_2 + OH \rightarrow H + H_2O$ [1], in which the very active oxidizing hydroxyl radicals disappear and hydrogen atoms arise. If hydrogen were to affect biological response to radiation, hydroxyl radicals would be strongly implicated as being responsible for part of the damage. Read[2] found no difference in the effect of radiation on growth of bean roots exposed in 14 atm. of hydrogen, or in 14 atm. of nitrogen. We have found that when gases are applied at 50 atm., hydrogen influences radiation damage differently from nitrogen.

Seedlings of *Vicia faba*[3] (Sutton's Prolific Longpod) were grown as described by Gray and Scholes. Root meristems were irradiated at 63 r. per min. with a Phillips 'Metallix' X-ray tube run at 190 kV. Reduction in growth-rate is known to be due to damage to the dividing cells of the meristem[3].

We have found that hydrogen at 50 atm. exerts a protective effect both in the presence and in the absence of oxygen. When 420 r. was given to root meristems in 50 atm. of pure hydrogen, significantly less ($P < 0{\cdot}01$) mortality was caused (fifteen survivors out of fifteen) than when given in 50 atm. of pure nitrogen (six survivors out of fifteen). 125 r. in 1 atm. of air plus 50 atm. hydrogen caused less mortality (thirteen survivors out of sixteen) and less reduction in growth than the same dose given in gas mixtures which contained 2 atm. hydrogen or less (thirty-eight survivors out of seventy-eight; see Fig. 1). Controls showed that the difference between the treatments was due to the presence of 50 atm. hydrogen during irradiation, and not to pressure or to the gas mixtures applied either before or after the irradiation. The depression of growth-rate six to eight days after irradiation gives a measure of radiation damage. Using Gray's data[4], we estimate the dose reduction factor for hydrogen at 50 atm. in the absence of oxygen, compared with that for nitrogen, to lie between 0·7 and 0·9. Further work is planned to obtain a more accurate value.

We interpret our results to mean that hydrogen molecules, when present in sufficiently high concentration inside the cell, alter the radiation effect by reacting with hydroxyl radicals. The hydrogen concentration must be high enough to allow hydrogen molecules to compete successfully for hydroxyl radicals with organic molecules present. This level is reached in bean roots between 14 and 50 atm. of hydrogen. Gray[4] found that the modification of radiation sensitivity in bean roots by carbon monoxide, ascribed mainly to a radical reaction, became apparent also at 40–60 atm. of the gas.

Some deductions can be made as to the damaging capacity of different radicals. Since in our experiments radiation in the presence of hydrogen results in less biological damage, we conclude that the oxidizing action of hydroxyl radicals is responsible for part of the damage caused by radiation in the bean root. If irradiation is carried out in pure nitrogen, hydrogen and hydroxyl radicals are formed from water molecules. If hydrogen is present, the concentration of hydroxyl radicals is reduced, and that of the hydrogen radicals correspondingly increased. Since biological damage is less in hydrogen than in nitrogen, it follows that hydroxyl radicals are more damaging than hydrogen radicals. If oxygen is present during irradiation, $HO_2$ radicals are formed by the reaction $H + O_2 \rightarrow HO_2$. The presence of oxygen during irradiation increases biological damage, indicating that $HO_2$ radicals are more damaging than hydrogen radicals. When hydrogen under pressure is present as well as oxygen, the number of $HO_2$ radicals would be expected to be larger than under any of the other conditions. Since $HO_2$ radicals are generally assumed to be more damaging in biological systems than hydroxyl radicals, the radiation effect would be expected to be greater when their number is increased. The contrary is, however, observed. We have no explanation to offer for this result at present.

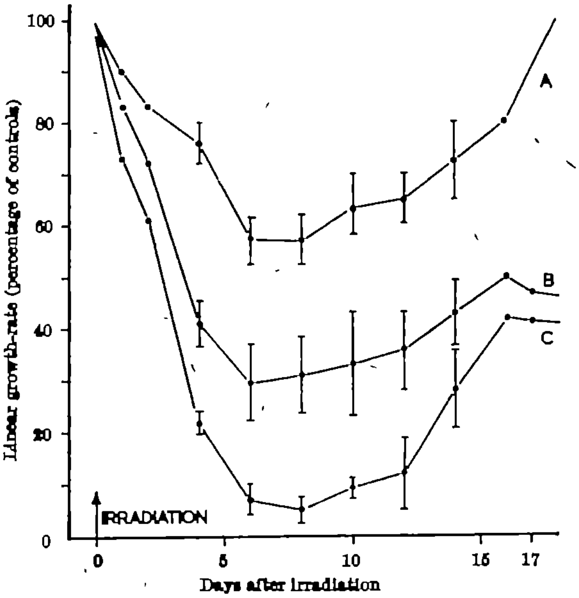

Fig. 1. Linear growth-rate of *Vicia faba* roots after exposure to 125 r. of 190 kV. X-rays plotted as per cent of growth-rate of control roots. Standard errors are shown. Curve *A*: exposure given under 50 atm. of hydrogen free of oxygen. Curve *B*: exposure given under 1 atm. of air plus 50 atm. hydrogen. Curve *C*: combined results of five groups exposed under (1) 1 atm. air; (2) 1 atm. oxygen; (3) 50 atm. oxygen; (4) 0·9 atm. oxygen plus 0·1 atm. hydrogen; (5) 48 atm. oxygen plus 2 atm. hydrogen. No differences were observed between these five groups

It is probable that the reduction of growth-rate in bean roots is due in part to 'direct action' of radiation, that is, to direct energy transfer to vital non-aqueous molecules, and in part to 'indirect action', that is, to energy absorbed in water molecules which exerts its influence via chemical intermediates. On the assumption that the 'direct' effect is not altered by dissolved gases within the cells, it is possible to ascribe an upper limit to that proportion of radiation damage which is due to the 'direct' effect. If damage in the presence of pure nitrogen is taken as 1, that in air has been measured as 2·8[4], and that in hydrogen may be taken as 0·8. The latter is an upper limit for the contribution of the 'direct' effect. If bean roots are irradiated in air, not more than one-third of the damage can be ascribed to the 'direct' effect.

## Deoxyribonucleic Acid Content of Marsupial Nuclei

THE deoxyribonucleic acid content of nuclei of different species of animals has been listed[1]; there appears to be a fairly regular increase from the sponges to the mammals. In the sponges the amount is about $0\cdot1 \times 10^{-12}$ gm. per diploid nucleus, in mammals it is about $6\cdot0 \times 10^{-12}$ gm. In birds the amount is only a little more than a third of that found in mammals, being about $2\cdot3 \times 10^{-12}$ gm. As pointed out by White[2], there is a distinct break in the distribution of chromosome numbers of the mammals, the Eutherian mammals with few exceptions having a haploid number of the order of 20–30, the marsupials of the order of 6–12. The birds and monotremes both have considerably larger numbers, and resemble the reptiles in this respect. There are, then, at least two major characters by which the higher vertebrates differ: first, the deoxyribonucleic acid content of the nucleus, and secondly, the number of chromosomes. The two do not necessarily parallel one another; but there seems to be a tendency for the groups with many chromosomes to have less deoxyribonucleic acid. The deoxyribonucleic acid content of marsupial nuclei has not heretofore been measured, and investigations of this group are reported here.

Three species of marsupial were investigated. Fresh testes of *Macropus rufus* (kangaroo) were kindly provided by Mr. Edgell, of Sydney, who removed them from three specimens, sliced them into two or three pieces and shook them in saline. Formaldehyde to a final concentration of 4 per cent was then added for preservation. Sperm were separated from this material by low-speed centrifugation and washed. The final preparations contained less than 10 per cent of other nuclei as judged by Feulgen-stained smears. The number of extra nuclei was estimated from the smears and included in the final count. Liver, gut mucosa, kidney and spleen nuclei were isolated from young *Trichosurus vulpecula* (possum) and *Perameles nasuta* (bandicoot) by the method of Marshak[3] and counted. Deoxyribonucleic acid was estimated by the method of Davidson, Frazer and Hutchison[4]. The results are shown in Table 1, with chromosome numbers (Sharman, G. B., personal communication).

Table 1

| Species | Tissue | Deoxyribonucleic acid per nucleus (gm. × $10^{-12}$) | Diploid chromosome number |
|---|---|---|---|
| *Macropus rufus* | Sperm | 2·9<br>3·1<br>3·4 | 18 + *XY* |
| *Trichosurus vulpecula* | Kidney<br>Spleen<br>Intestine<br>Liver | 6·6<br>6·0<br>6·4<br>5·0 | 18 + *XY* |
| *Perameles nasuta* | Kidney<br>Spleen<br>Intestine<br>Liver | 8·9<br>9·9<br>8·8<br>9·4 | 12 + *XX* |

The deoxyribonucleic acid content of marsupial nuclei is very similar to that of Eutherian mammals and different from that of birds. We cannot account for the rather high amount found in the nuclei of *Perameles*; it is certainly not less than in Eutherian mammals. We may conclude that the big increase in nucleic acid content of the nucleus which differentiates birds and mammals and appears to accompany a difference in chromosome number took place before mammals were differentiated into Eutherian and Marsupial forms.

## Crystalline Cytochrome c from the King Penguin

CYTOCHROME *c* was prepared from skeletal (mainly pectoral) muscle of the king penguin (*Aptenodytes patagonica*) by the method of Keilin and Hartree[1,2] and further purified with the aid of the ion-exchange resin 'Amberlite *XE*-64', by the method of Margoliash[3].

Attempts were made to crystallize the protein by saturating 1–2 per cent aqueous solutions with ammonium sulphate at various *p*H's. From solutions of ferri-cytochrome only spherulitic globules were obtained, which did, however, exhibit birefringence between crossed nicols. But if a neutral solution of cytochrome, almost saturated with ammonium sulphate, was reduced by adding a trace of sodium dithionite, the reduced cytochrome was precipitated slowly in the form of true crystals possessing flat faces and exhibiting straight extinction between crossed nicols. The crystals have the form of thin plates, as shown in Fig. 1. Crystalline preparations of cytochrome *c* have not hitherto been reported in the literature.

The precipitate, which was almost completely crystalline, was centrifuged off and its enzymatic activity compared with that of purified horse cytochrome *c*. Two methods were used: (*a*) the cytochrome oxidase system with ascorbic acid as reducing

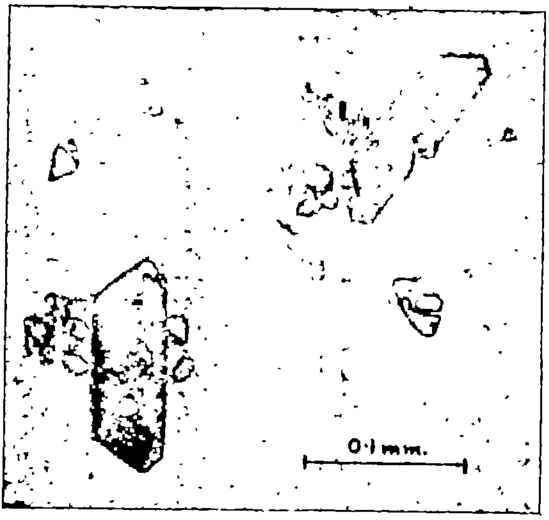

Fig. 1. Two crystals of cytochrome c (lower left and upper right)

agent, and (b) the succinic oxidase system (Keilin and Hartree[3,4], Slater[5]), using excess of heart muscle preparations deficient in cytochrome c (Tsou[6]) and limiting amounts of cytochrome c. By each method the activity of the crystalline king penguin cytochrome c was found to be, within the limits of error, identical with that of horse cytochrome c.

Measurements of the iron content and absorption spectrum of king penguin cytochrome c were made using purified stock solutions. The iron content was found to be 0·430 and 0·444 per cent in two separate preparations (for the horse heart pigment the standard figures range from 0·43 to 0·46 per cent iron). The absorption spectra of ferri- and ferro-cytochrome c of the king penguin were found to be identical with those of horse and beef cytochrome c within the limits of error. Thus the extinction coefficients of the α-, β- and Soret bands correspond within 3 per cent to the values given for beef cytochrome c by Theorell[7]. The ratio of the extinction coefficients of the reduced form at 550 mμ to that of the oxidized form at 280 mμ was found to be 1·15, as compared with 1·17 for beef (Paleus[8]).

I thank the Director of the Zoological Society of London for providing the king penguin muscle, and Prof. D. Keilin, Dr. E. F. Hartree and Dr. A. Tissières of the Molteno Institute, University of Cambridge, for the sample of purified horse cytochrome c, for the heart-muscle succinic oxidase preparation and for providing facilities and help in carrying out the determination of enzymatic activity.

## Enzymatic Conversion of Alpha-Formamidinoglutaric Acid to Glutamic Acid by Rat Liver

A previous report from this laboratory[1] gave evidence that histidine is converted to glutamic acid *in vivo* and *in vitro*. The *in vitro* experiment, done with guinea pig-liver slices, is subject to the criticism that degradation of α-formamidinoglutaric acid, the principal conversion product, may have occurred non-enzymatically. Direct evidence for such a conversion has been found so far only in micro-organisms adapted to histidine[2]. I have now shown the presence in rat liver of an enzyme which degrades α-formamidinoglutaric acid (N-formiminoglutamic acid) to glutamic acid.

Radioactive α-formamidinoglutaric acid was prepared by incubating homogenized rat liver with L-histidine-$^{14}$COOH (20,000 counts/min. per mgm. or 3,100 counts/min. per μmole) at 37° C. for 18 hr., precipitating the proteins with trichloracetic acid and separating the radioactive products by elution with hydrochloric acid from a column of 'Dowex-50' resin. The fraction containing α-formamidinoglutaric acid (200–280 ml. of 1·5 $N$ hydrochloric acid) was lyophilized and stored in aqueous solution at $p$H 2–3. The radioactive α-formamidinoglutaric acid had an $R_F$ on paper of 0·28 with 3 parts $n$-propanol/1 part 1·0 $N$ acetic acid as solvent. It gave a delayed ninhydrin reaction (purple) and an immediately positive alkaline ferricyanide–nitroprusside reaction (pink)[3]. Synthetic α-formamidinoglutaric acid, kindly supplied by Dr. Alexander Miller[4], had identical $R_F$ and colour reactions. α-Formamidinoglutaric acid is unstable in the presence of 1·0 $N$ sodium hydroxide and is converted to a compound identical, by the above column and paper chromatographic procedures, with glutamic acid.

α-Formamidinoglutaric acid so prepared was converted to glutamic acid enzymatically by a soluble rat-liver preparation. A rat liver was homogenized at 0–4° C. in 20 ml. of 0·1 $M$ potassium phosphate buffer, $p$H 7·8, and centrifuged at 100,000 $g$ for 1 hr. The clear supernatant (protein nitrogen = 2·0–3·5 mgm./ml.) was incubated at 37° C. for 2 hr. in varying concentrations in a total volume of 1·0 ml. (0·1 $M$ in potassium phosphate buffer, $p$H 7·8) with 2,000 counts/min. (= 0·65 μmole) α-formamidinoglutaric acid. The reaction was stopped with trichloracetic acid, and the filtrate put on a small column (0·3 cm. × 55 cm.) of 'Dowex-50'. The column was eluted with 1·5 $N$ hydrochloric acid, and fractions of 0·5 ml. were collected. These were evaporated to dryness and tested for radioactivity. Unaltered α-formamidinoglutaric acid was recovered in fractions 18–25. A radioactive peak in fractions 11–15 was identical on paper chromatography with glutamic acid, giving an immediate ninhydrin colour (purple) and no colour with alkaline ferricyanide – nitroprusside. No other radioactive peaks were obtained.

Enzyme activity was measured with enzyme (1) unmodified, in varying concentrations, (2) boiled for 10 min., (3) incubated in the presence of 0·01 $M$ glutathione, (4) incubated in the presence of 0·0025 $M$ $p$-chloromercurobenzoate, (5) pre-incubated 2 hr. at 37° C. with and without glutathione, and (6) incubated in the presence of folic acid ($1 \times 10^{-4}$ to $5 \times 10^{-3}$ $M$) with glutathione. The percentage conversions to glutamic acid (calculated from amounts formed and α-formamidinoglutaric acid remaining) under various conditions are shown in Table 1.

able 1. CONVERSION OF α-FORMAMIDINOGLUTARIC ACID TO GLUTAMIC ACID

| Enzyme | Protein nitrogen (mgm.) | Percentage conversion to glutamic acid |
|---|---|---|
| None | 0 | 0 |
| Boiled | 0 | 0 |
| Unmodified | 1·0 | 100 |
| Unmodified | 0·6 | 88 |
| Unmodified | 0·5 | 66 |
| Unmodified | 0·3 | 36 |
| Unmodified | 0·2 | 20 |
| Glutathione added | 0·3 | 74 |
| Folic acid + glutathione | 0·3 | 0 |
| p-Chloromercuribenzoate | 1·0 | 22 |
| Preincubated | 1·0 | 83 |
| Preincubated + glutathione | 1·0 | 85 |

It is concluded that rat liver contains an enzyme, rhich can be solubilized, and which catalyses the deradation of α-formamidinoglutaric acid to glutamic oid, without the accumulation of any intermediate. imilar homogenates degrade histidine to α-formmidinoglutaric acid much more rapidly. The nzyme which degrades α-formamidinoglutaric acid s unstable, but less so in the presence of glutathione. ow activity and instability of this enzyme probably ccount for the accumulation of the acid when istidine is incubated with liver homogenate. Folic cid inhibits the enzyme, thereby raising the question rhether it is acting as an analogue of a coenzyme uch as tetrahydrofolic acid.

## Benzene-$^{14}C_1$ from the Neutron Irradiation of the Clathrate with Ammoniacal Nickel Cyanide

THE use of *in situ* production of compounds ontaining carbon-14 by the neutron irradiation of itrogen-containing organic compounds or mixtures f nitrogen-containing compounds with organic comounds for the synthesis of labelled organic comounds has been suggested by recent work on this ubject[1,2]. The neutron irradiation of the clathrate f ammoniacal nickel cyanide and benzene was ported on by M. Zifferero[3] in Genoa last year. We ave carried out an irradiation of this compound to rovide data for comparison and to test a purificaion method for labelled compounds produced in this ay.

Pile irradiation conditions with regard to the ratio f fast to slow neutrons and the intensity of the amma-field vary from one installation to another. rrangement of the sample in the lattice of a pile ith regard to proximity of the fuel rods and quantity of absorber surrounding the sample will also affect the exact irradiation conditions.

A 21·4-gm. sample of clathrate prepared by the method of Hofmann and Hochtlen[4] was irradiated in the Brookhaven pile for thirteen days at a sample temperature of 30° C. The thermal neutron flux was about $4 \times 10^{12}$ neutrons/cm.$^2$ sec., the fast neutron flux about $10^{11}$, and the gamma flux was equivalent to about $5 \times 10^6$ r./hr. The irradiated sample proved to be quite γ-active. This activity was identified as cobalt-58 by Dr. M. L. Perlman of this Laboratory. The probable source is the $^{58}$Ni($n,p$)$^{58}$Co reaction. The clathrate was decomposed by the method of Turner and Warne[5] with some modification of the collection system. The benzene was dried and distilled from sodium. To allow greater ease in manipulation, distilled active benzene was diluted with inactive benzene and the dilute sample fractionated twice in a 50-plate (*n*-heptane, methyl *cyclo*hexane calibration) concentric tube column.

*Ortho*-benzoylbenzoic acid was prepared from the benzene, and anthraquinone was then made from this derivative. Careful purification of each derivative showed no change in specific activity relative to the parent benzene when corrected for the introduction of inactive carbons. Our results are presented in Table 1.

Table 1

| Sample | Carbon-14 activity (mμc./mgm. carbon) |
|---|---|
| Irradiated clathrate | 29·6 |
| Recovered benzene distilled from sodium | 0·835 |
| Fractionation No. 1 of diluted benzene | |
| Head cut[a] | 0·068 |
| Centre cut | 0·065 |
| Tail cut | 0·064 |
| Fractionation No. 2 of diluted benzene[b] | |
| Head cut[c] | 0·066 |
| Tail cut | 0·062 |
| o-Benzoyl benzoic acid | 0·061[d] |
| Anthraquinone | 0·063[d] |
| Corrected value for recovered benzene[e] | 0·630 |

[a] These fractions were taken from a boiling plateau with a 0·2 deg. range.

[b] Three cuts from previous fractionation combined.

[c] Boiling points of cuts within 0·05 deg. of each other.

[d] Corrected for dilution by eight additional carbons.

[e] Using 0·062 as the value for diluted benzene at constant specific activity.

Quantitative recovery of benzene was not attempted; however, very little is lost by radiation damage. Difficulty in obtaining precise carbon values for the clathrate made it necessary to rely on the nickel and nitrogen values in order to calculate the total amount of benzene present. The carbon-14 activity as benzene represents 1·44 ± 0·13 per cent of the total carbon-14 activity produced. The stated error is exclusive of any error introduced in the radioactive assay. The percentage is calculated by simply using the following formula:

$$\frac{\text{Benzene activity (m}\mu\text{c./mgm. carbon)}}{\text{Clathrate activity (m}\mu\text{c./mgm. carbon)}} \times \frac{\text{total mgm. carbon due to benzene}}{\text{total mgm. carbon in sample used}} \times 100 = \%\text{ of total activity}$$

Had the analysis been ideal, the carbon-14 activity in benzene would have been 1·59 per cent.

The value reported by M. Zifferero[3] was 4 per cent. The method of calculation was not stated.

The actual levels of activity produced in recognizable compounds is still rather lower than one might desire for labelled compounds. In a system where a carbon analogue is produced, such as the acridine to anthracene sequence[6], it may in the future be possible to isolate the analogue free from carrier. It must be borne in mind, however, that at the present time these compounds are formed in quantities too small for practicable separation.

Investigations on the chemical fate of a recoiling carbon-14 atom are being carried out. It is hoped that the increasing amount of research in this field will provide accurate data for the correlation of re-entry versus total carbon-14 production in a given system. In addition, the method may become a valuable synthetic tool for the organic chemist.

This investigation was carried out under the auspices of the U.S. Atomic Energy Commission.

## Steric Effects in the Formation of Copper and Cobalt Complexes with the Epimeric Salicylidenementhylamines

In a previous communication[1], it was reported that cobaltous ions do not react readily with salicylidene-aniline bases bearing ortho substituents on the aniline ring. In the present communication are reported some further attempts to prepare similar complexes of cobalt and copper, using as the amine components of the salicylidene bases four epimeric forms of menthylamine which, with bulky *iso*propyl substituents and nonplanar ring forms, may be expected to exert considerable steric resistance to a tetrahedral grouping of ligands about cobalt ions. The complexes were prepared by mixing aqueous solutions of the metal acetates with an alcoholic solution of the salicylidene base[2]. The results of this work are indicated in Table 1, the complexes isolated being of the form *bis* (salicylidenementhylamine) cobalt (copper).

Table 1

| Amine component | Co | Cu |
|---|---|---|
| Cyclohexylamine | + | + |
| (−)-Menthylamine | + | + |
| (+)-*neo*Menthylamine | − | − |
| (+)-*iso*Menthylamine | 0 | + |
| (±)-*neoiso*Menthylamine | 0 | + |

+ = isolation of the complex *bis* (salicylideneamine) *M*.
− = no reaction: formation of metal hydroxide and unchanged Schiff's base.
0 = formation of oils or tar and unchanged Schiff's base.

The inability of salicylidene-(+)-*neo*menthylamine to form complexes with either cobalt or copper points to a strong steric hindrance with respect to both the nitrogen atom and the phenolic hydroxyl in this case. (−)-Menthylamine and (+)-*neo*menthylamine differ only in the configuration of the amino-group at $C_{(3)}$, and the ready formation of complexes with (−)-menthylamine (with both copper and cobalt) is explainable on the basis of this relationship. A consideration of the probable conformations of strainless rings for the amines[3,4] suggests that the *cyclo*hexane ring contributes considerably to the steric hindrance preventing complex formation with (+)-*neo*menthylamine, in which the amino-group occupies an axial position, whereas no such effect impedes complex formation with (−)-menthylamine, which has an equatorial amino-group.

With copper and salicylidene-(+)-*iso*menthylamine the expected complex was isolated as readily as in the case of (−)-menthylamine; but with cobalt the reaction produced only a reddish tar together with unchanged base, and no solid complex could be isolated from the mixture. It is not immediately obvious why cobalt does not form a derivative with the (+)-*iso*menthylamine base while copper does, even on the assumption of a tetrahedral arrangement for the expected cobalt complex. This difference observed between the behaviour of salicylidene-(−)-menthylamine and that of salicylidene-(+)-*iso*menthylamine towards cobalt ions was not expected, as the difference between the two amines is believed to be only in the position of the methyl group (1*e* in the case of menthylamine and 1*p* in *iso*menthylamine[4]).

Although no complex could be obtained with cobalt and salicylidene-(±)-*neoiso*menthylamine, but only a reddish tar and unchanged Schiff's base, the copper derivative, on the other hand, was readily isolated. The lesser hindrance towards complex formation of (±)-*neoiso*menthylamine compared with that of (+)-*neo*menthylamine is in agreement with the greater reactivity of *neoiso*menthol over that of *neo*menthol towards acid chlorides[5]. If the inability of salicylidene-(+)-*neo*menthylamine to form complexes with both copper and cobalt ions is due chiefly to the spatial arrangement of the *iso*propyl and amino-groups, it seems unlikely that *neoiso*menthylamine has, in these reactions at least, a conformation in which the amino-group occupies an axial position. Rather, our results tend to support the view that *neoiso*menthyl derivatives are examples of conformational instability (Mills, J. A., private communication), and that it is possible for the amino-group in *neoiso*menthylamine to adopt an equatorial position[6].

Relative $pK_a$ values have been determined for the four menthylamine epimers by potentiometric titration in 50 per cent aqueous ethanol against hydrochloric acid. As can be seen from Table 2, the order of decreasing basic strength is *iso*menthylamine, menthylamine, *neo*menthylamine, and *neoiso*menthylamine.

The apparent non-reactivity of several of the salicylidene-menthylamine bases with cobalt, and of the *neo*menthylamine derivative with copper and cobalt cannot be ascribed to differences in the basicities of the amines. They are all comparably strong bases, and the electron density on the nitrogen atom in each case should not differ greatly throughout the series. Steric effects related to the tendency to form planar (copper) or tetrahedral (cobalt) derivatives as outlined above seem to provide the only

Table 2. $pK_a$ Values of Four Epimeric Menthylamines determined in 50 per cent Aqueous Ethanol at 20°

| | $pK_a$ |
|---|---|
| (+)-*iso*Menthylamine | 9·93 |
| (−)-Menthylamine | 9·78 |
| (+)-*neo*Menthylamine | 9·69 |
| (−)-*neoiso*Menthylamine | 9·47 |

other explanation of the difference in reactivity between copper and cobalt with the various bases studied.

## Crystallization of Silver Chromate

The precipitation of silver chromate from its supersaturated solutions has been studied by van Hook[1], who concluded that crystallization could be represented as a two-step process: first, an induction period varying inversely with the volume of seed suspension used, during which the principal action was the generation of crystal nuclei; secondly, a bimolecular growth of these nuclei.

It is well known that the inoculation of supersaturated solutions with seed crystals results in the growth of these added crystals rather than the formation of crystal nuclei[2]. Crystallization of silver chloride begins immediately on seeding a supersaturated solution. Delayed crystallization, however, similar to that reported by van Hook, is encountered when seed suspensions are aged before use in the presence of suitable poisoning substances such as eosine[3]. The observed inverse relationship between the duration of these induction periods and the volumes of poisoned suspension used suggests that the results of van Hook were due to the presence of adsorbed contaminant at the surface of aged silver chromate crystals. The present work was designed to test this suggestion.

Preliminary experiments confirmed the existence of a well-defined critical supersaturation: it was possible to prepare stable solutions of silver chromate in which the molar concentration product $[Ag^+]^2[CrO_4^{=}]$ exceeded the solubility value by more than 300 per cent. The solubility of silver chromate at 25° was determined by the equilibration (*a*) of pure solid with conductivity water ($0{\cdot}923 \times 10^{-4}$ moles/l.), and (*b*) of highly supersaturated solutions ($0{\cdot}931 \times 10^{-4}$ moles/l.).

Crystallization experiments were carried out at 25° using the conductivity technique described elsewhere[2]. Supersaturated solutions of silver chromate were prepared in a stirred conductivity cell by mixing silver nitrate and potassium chromate solutions, and crystallization was induced by the addition of a small volume, usually 5 ml., of the appropriate seed suspension. Some typical results are shown in Fig. 1, in which the reciprocal of the resistance of the solution (a measure of the extent of crystallization) is plotted against time.

Solubility product = $3{\cdot}186 \times 10^{-12}$

| Experiment | Initial concentrations moles/l. × $10^4$ $[Ag^+]$ | Initial concentrations moles/l. × $10^4$ $[CrO_4^{=}]$ | $[Ag^+]^2[CrO_4^{=}]$ × $10^{12}$ |
|---|---|---|---|
| 15 | 2·234 | 1·129 | 5·635 |
| 17 | 2·250 | 1·130 | 5·720 |
| 23 | 2·254 | 1·127 | 5·726 |
| 24 | 3·580 | 0·448 | 5·725 |
| 26 | 1·420 | 2·840 | 5·727 |

An aged seed suspension, prepared by crystallization from boiling saturated silver chromate solution, was used in Exp. 17 and no change in conductivity was detected for at least four hours, even though a sensible supersaturation persisted. Thorough washing of this aged suspension with boiling conductivity water before use in Exp. 15 resulted in a substantial reduction in the time of induction. In Exps. 23, 24 and 26, the use of freshly precipitated seed suspension of available growth area less than half that of the aged suspension enabled crystallization to start immediately on seeding. These results provide conclusive evidence that any induction effect is due to contamination of the surface of aged crystals. Hydrolysis products, the most likely contaminants, might include any or all of the species $HCrO_4^-$, $AgOH$, $Ag_2OH^+$.

It is seen from Fig. 2 that the rate of crystallization, $-dm/dt$ (moles.l.$^{-1}$min.$^{-1}$), obtained from the curves in Fig. 1, is best interpreted in terms of third-order

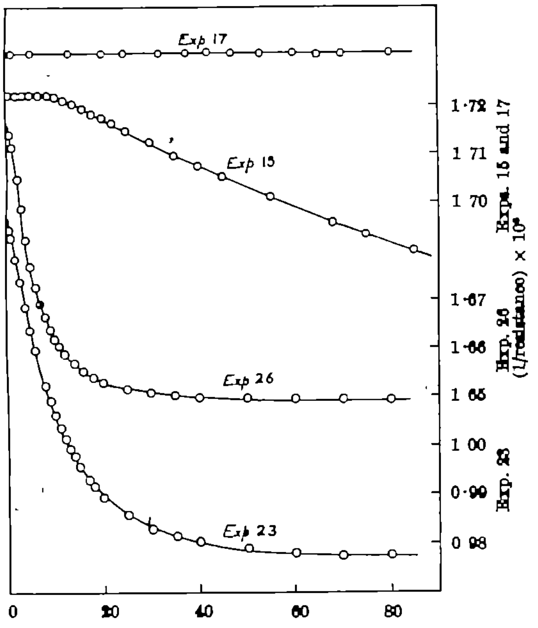

Fig. 1. Time plots of the reciprocal of the resistance of the solution

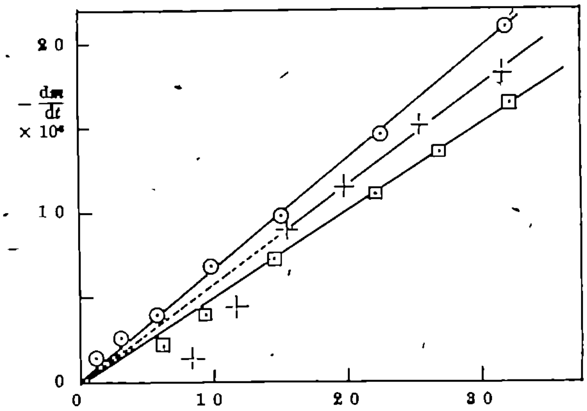

Fig. 2. Third-order kinetic plot. Exp. 23, ○; exp. 26, +; exp. 24, ⊡

kinetics: $-\mathrm{d}m/\mathrm{d}t = k(P - P_s)^2$, where $k$ is a constant, $P = \{[\mathrm{Ag^+}]^2[\mathrm{CrO_4^-}]\}^{1/3}$ at any instant, and $P_s$ is its solubility value. By analogy with the observed second-order kinetics for crystallization of silver chloride[3], these results may be interpreted in terms of the simultaneous arrival of two silver ions and one chromate ion at the hydrated monolayer assumed to be adsorbed at the surface of the crystals.

At non-equivalent ionic concentrations of silver and chromate, the presence of an excess of chromate ions (Exp. 26) produces a greater reduction in the rate of crystallization in the later stages than is to be expected for a termolecular process. This may be due to the adsorption at the growing surface of $\mathrm{HCrO_4^-}$ ions, formed by hydrolysis of chromate ions, effectively reducing the number of available growth sites.

Studies of both crystallization and dissolution processes are being continued.

We thank Prof. C. W. Davies for his interest in the work.

## Radioactivity of Zircons

Mügge[1] recorded the α-particle emission of zircons by sprinkling them on a photographic plate and, more recently, Tyler and Marais[2] have used a similar technique for determining the relative radioactivities of mineral grains. In both experiments, the mineral grains were mounted on the surface of the photographic emulsion.

We have attempted quantitative measurement and comparison of the α-activities of zircons by embedding them completely in 'Nuclear Research' photographic emulsions, using a method very similar to that used by King, Traczyk and Harris[3] in the study of Protozoa by electron-track radiography.

Zircons obtained from a Triassic sandstone of the Bristol district were sprinkled evenly on the emulsion surface of Ilford *C2*, 50μ, 'Nuclear Research' plates, and some *C2* gel was liquefied and poured over them, so that the grains were completely surrounded by photographic emulsion. The plates were dried in a current of filtered air for two hours at room temperature, and then left to 'expose' for 20 days at 2–3° C. in a light-tight box in a refrigerator. Processing revealed α-particle tracks surrounding, and in contact with, the zircons.

Preliminary examination showed that the zircons could be divided into a strongly radioactive group (Fig. 1) and a weakly radioactive group (Fig. 2).

More precise information was obtained by dividing the estimated total surface area of each grain by the total number of α-tracks associated with it. When this was done, it was seen that zircons of four activities were present with mean area/emission ratios of 18, 40, 85 and 250.

Zircon is probably one of the first minerals to crystallize from a rock melt, and since uranium and thorium can substitute for zirconium in the zirconium silicate structure[4], the specific activity of a zircon can be considered as a function of the uranium–thorium concentration in the parent rock magma.

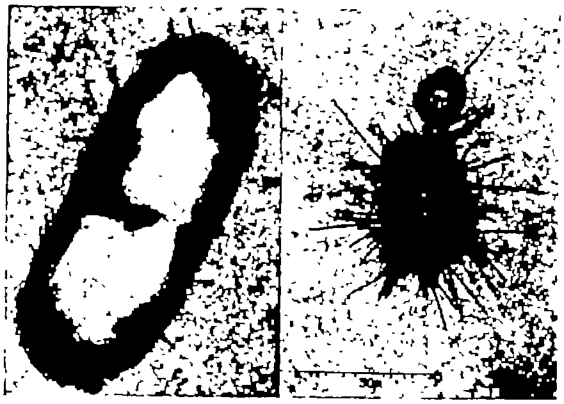

Fig. 1. Zircon grain of low activity from Triassic sandstone, Bristol
Fig. 2. Zircon grain of high activity from Triassic sandstone, Bristol

Zircon is therefore 'labelled', and, we suggest, can be used as a natural radioactive tracer. Since it is an extremely durable mineral[5], the technique described should prove useful in many petrological problems, particularly those of provenance in sedimentary petrology.

A more detailed account of this work will be published elsewhere.

## The Graphite–Diamond Equilibrium

There have very recently been two recalculations of the graphite–diamond equilibrium, one by Liljeblad[1] and the other by Berman and Simon[2], who also included a brief historical survey. Liljeblad did not make use of the most recent experimental data, whereas in the second paper the latest published material was incorporated as well as new measurements of the expansion coefficient of diamond, made by one of us (J. T.). Fig. 1 shows the two calculated equilibrium curves; while Liljeblad's curve goes through a maximum of about 62,000 atm. near 3,000° K., Berman and Simon arrived at a linear extrapolation above 1,200° K., which follows the equation:

$$P_{(\mathrm{atm.})} = 7{,}000 + 27\,T_{(°\mathrm{K.})}$$

The technical difficulty in synthesizing diamond is that of achieving, simultaneously, the high temperature at which the reaction velocity will be appreciable and the high pressure under which diamond is stable at such a temperature. If the equilibrium curve is linear at high temperatures, there is no escape from this difficulty in an equilibrium synthesis. If Liljeblad is correct, the obvious solution would be to work at very high temperatures and so combine the great reaction velocity with a smaller pressure. In view of the increased interest in this problem, associated with the recent successful synthesis of diamond[3], it seems appropriate to consider the reason for the discrepancy between the calculations.

New values of the densities and of the low-temperature specific heats of diamond and graphite introduce only slight changes, and the difference between the two curves is almost entirely due to the different values of the expansion coefficient of diamond used in the calculations. This coefficient is important because it affects the difference of the specific heats,

$$C_p - C_v = \frac{(3\alpha)^2 TV}{K}$$

where $\alpha$ is coefficient of linear expansion, $V$ is atomic volume and $K$ is compressibility. Although $C_v$ for diamond and graphite may be equal at high temperatures, a large expansion coefficient, combined with low compressibility, would make $C_p$ for diamond much bigger than for graphite.

High-temperature determinations of the coefficient of expansion of diamond have been made by Joly[4], using an optical method, and by Krishnan[5], using X-rays. The results are shown in Fig. 2, together with the low-temperature measurements of Dembowska (quoted by Röntgen[6]). If Joly's values were correct we should have a very severe violation of Grüneisen's law of the proportionality of thermal expansion coefficient to specific heat. It is true that slight deviations from this law have recently been observed at low temperatures[7]; but it is difficult to see how a serious departure could occur at high temperatures. As a further check, the Grüneisen constant, $\gamma$, can be calculated from the relation, [illegible] $= b\gamma C_v/V$, and for most substances $\gamma$ is found [illegible] lie between 1 and 2. Grüneisen[8] had derived [illegible]es of 1·1–1·2 from Dembowska's measurements, [illegible] Krishnan showed that his results satisfied the [illegible] relation with $\gamma$ about 1·3. According to [illegible]s, $\gamma$ would increase rapidly to more than 3. [illegible]epting such a departure from Grüneisen's [illegible]t be convinced of the reliability of the measurements involved. A consideration of Joly's apparatus, however, led us to doubt his accuracy and to undertake a new X-ray determination of the lattice constant up to about 1,200° K. Fuller details of these experiments will be published later, and in Fig. 2 we only show the high-temperature end. At 1,200° K., we find $\gamma$ to be 1·3, in agreement with Krishnan's value for lower temperatures. To show more fully how well the expansion, according to the new measurements, obeys Grüneisen's law, we give in Table 1 the ratio of the change of lattice constant to the change of heat content, over several temperature intervals. It can be seen that, apart from a suggestion of a very slight anomaly between 400° and 600° K., the ratio of these two quantities remains sensibly constant. The thermal expansion of diamond is therefore quite normal, and the only justifiable extrapolation to higher temperatures should follow Grüneisen's law.

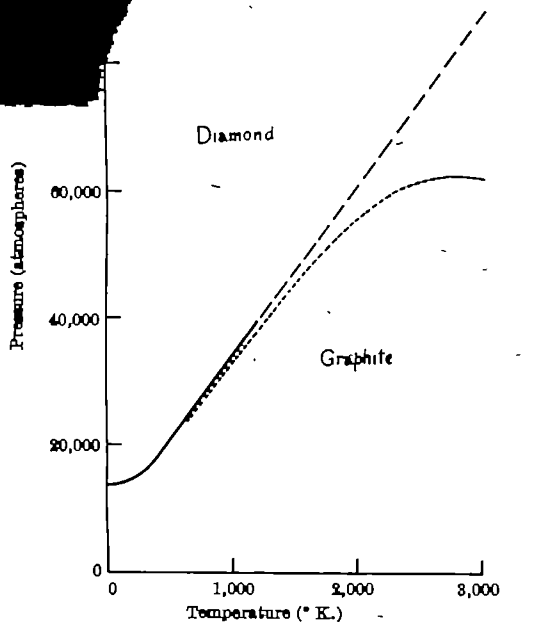

Fig. 1. Calculated graphite-diamond equilibrium curve. Berman and Simon, ———, calculated to 1,200° K.; — —, linear extrapolation. Liljeblad, ———

Thus Joly's results are certainly in error. Liljeblad only states the value he has assumed for $3\alpha$ at 2,300° K. ($\alpha$ is plotted in Fig. 2), without giving his sources. This unjustifiably high value would increase $C_p - C_v$ of diamond to 2 cal./mol.-deg. and is

responsible for the maximum in Liljeblad's equilibrium curve between 2,500° and 3,000° K. With the Grüneisen extrapolation of α, $C_p - C_v$ of diamond is only 0·2 cal./mol.-deg. at 2,300° K., which is little greater than the value for graphite. Up to the highest temperatures considered, $C_{p(\text{diamond})} - C_{p(\text{graphite})}$ is therefore sufficiently near zero so that, with the other uncertainties, of a similar order of magnitude, which were discussed in Berman and Simon's paper, a linear extrapolation of the equilibrium curve is as accurate as the existing data warrant.

## Location on Jupiter of a Source of Radio Noise

A search of old records of cosmic noise, taken in the Radiophysics Laboratory at 18·3 Mc./s., has confirmed the discovery, by Burke and Franklin[1], of radio radiation from Jupiter, and has further shown that in 1951 the radio radiation came from a very localized region of the planet.

The records studied fall into two series. The first series comprised records, using an aerial with beamwidth 17°, taken at intervals during the period October 1950–April 1951. Radiation from Jupiter appeared on about one-half of the days on which records were suitable (correct aerial direction, no obvious interference, etc.), and it was clear that the right ascension of the source changed with that of Jupiter. For some of these records more accurate direction-finding was possible using a split-beam technique, and these records proved that the position of the source was within ± 1° of Jupiter.

The second series of records had been taken with the aerial modified in such a way that the beam was still narrow in declination but was very broad in hour angle. Because of its broad beam it was capable of receiving signals from an extra-terrestrial source for nearly eight hours per day—a time which would cover nearly one complete rotation of Jupiter. This series of records, from August 15 to October 2, 1951, revealed Jupiter radiation on twenty-seven out of the thirty days on which there were suitable records, although on all days the bursts of radiation came in groups only an hour or two in duration.

A most interesting new fact coming out of the examination of these records was the very close relation between the times of occurrence of bursts and the rotation of Jupiter. For each record the times of activity were noted. Fig. 1 shows the longitudes of the central meridian during the times when bursts were received. The equatorial regions of the visible surface of Jupiter rotate more rapidly than the remainder of the planet and two conventional systems of zenocentric longitude are used. System I, which applies to the equatorial regions, is based on a rotation period of about 9h. 50m.; system II on a rotation period of about 9h. 55m. It will be seen that the lines indicating times of occurrence of bursts are almost directly under one another when plotted against system II longitudes and show a steady drift towards increasing longitudes in system I. Closer examination shows that there is actually a small negative drift in the system II diagram. These drifts imply that the source of radiation had a rotation period slightly shorter than that adopted for the calculation of system II longitudes; the period of rotation is found to be 9h. 55m. 13s., with an estimated probable error of ± 5s.

After allowing for the slight drift in longitudes, all the lines in Fig. 1 were superimposed to give a histogram of the frequency of occurrence of the noise for 5° intervals of central meridian longitude. This is shown in Fig. 2, the longitudes being system *II* longitudes on August 14. This figure shows that for a band of longitudes centred on 67° and extending from about 0° to 135°, the frequency of occurrence was much greater than outside this band. This suggests an origin in a very localized source Jupiter. Since there were about 120 rotations Jupiter during the period of the observations which the figure is based, the probability tha effect observed is due to chance is extremel

Fox[3] has given a summary of the obs Jupiter at this time which were comm the Jupiter Section of the British Association. A disturbance at the bou the South Temperate Zone and the So Belt, which was observed for several observed rotation period of 9h. 55 the radio source. All the other belt with system II were either faint, wi markings, or moved slightly more system II. Fox gave a sketch by E. J. depicted the most visually active region Temperate Belt at the end of November radio observations ceased on Octob allowing for a continuing drift in l longitude of the radio source on Nove have crossed the middle of one of white markings in Reese's sketch although the identification is not prov doubt, it seems very probable that thi

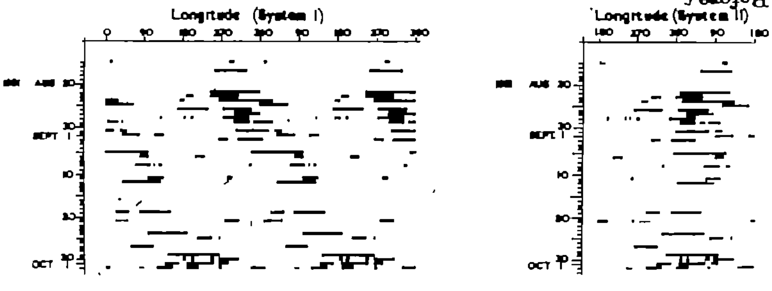

Fig. 1. Periods of occurrence of 18·3 Mc./s. radiation from Jupiter plotted against longitude of the central meridian at the time of observation

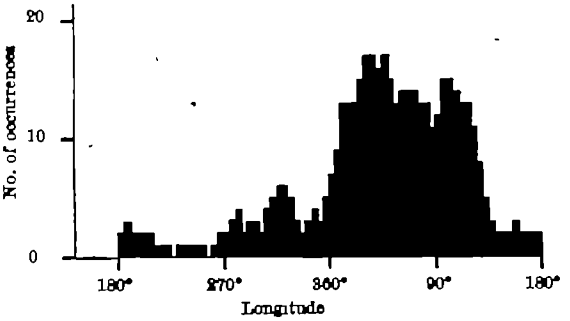

Fig. 2. Frequency of occurrence of 18 3 Mc./s. radiation from Jupiter for intervals of 5° in longitude (based on a rotation period of 9h 55m. 13s.). The longitudes are system II longitudes on August 14, 1951

turbed region was responsible for the radio radiation, the most intense source lying in one of the white spots at the southern edge of the South Temperate Belt.

The mechanism of origin of the radiation is still unknown. Observations during the past few months have confirmed a result suggested by the 1950–51 observations that the individual bursts have durations ranging from fractions of a second to many seconds. An origin in electrical discharges analogous to terrestrial atmospherics is not unlikely. The recent observations are also consistent with the hypothesis of a localized source of the radiation.

A full discussion of the 1950–51 observations will be given in a paper submitted to the *Australian Journal of Physics*.

## Mechanism of Uniform Field Breakdown in Hydrogen

Any assessment of the validity of theories of electrical breakdown of gases in uniform fields requires an accurate knowledge of breakdown potentials and of the magnitudes of the fundamental ionization processes involved. Preferably these quantities should be determined under the same experimental conditions.

Some years ago, experiments were started in this laboratory to carry out such measurements with the object of checking the streamer theory[1] over a wide range of values of $pd$, the product of gas-pressure and gap-length. Since that time, the results of experiments of F. Llewellyn-Jones and his co-workers[2,3] have been published. Their results demonstrate that the Townsend theory of breakdown, involving (i) a primary ionization process in the gas denoted by the Townsend coefficient $\alpha$, and (ii) a secondary process here denoted by $\gamma$ probably taking place at the cathode, is adequate to explain the initiation of breakdown in both air and nitrogen up to a value of $pd$ of about 1,000 cm. mm. mercury. Our results in air lend support to this view, and it is the purpose of this communication to report the results of similar experiments in hydrogen.

Determinations have been made, at a number of values of the ratio of electric field-strength to pressure, $E/p$, of the growth of current as the gap-length, and consequently $pd$, is increased to within a few per cent of the breakdown value. A plot of ln $i$ against gap-length $d$ has a form similar to that obtained for air, having an initial linear region from which a value of the Townsend coefficient $\alpha$ can be obtained, followed by a region of increasing gradient indicating the presence of a secondary ionization process. A typical series of curves obtained at 700 mm. mercury pressure is shown in Fig. 1, and similar curves have been obtained at 300 mm. and 100 mm. mercury pressure.

The values of $\alpha/p$ obtained from the curves are shown in Fig. 2, together with the results in hydrogen of previous workers. It has been found that in the range of $E/p$ where the results obtained at different pressures overlap, there is agreement in the values of $\alpha/p$ within the limits of experimental error. The fact that $\alpha/p$ is truly a function of $E/p$ has not previously been experimentally demonstrated over a wide pressure range.

There is general agreement in the values of $\alpha/p$ obtained by all workers when $E/p > 25$ volts/cm./mm. mercury; but for $E/p < 22$ the results of this work show considerable divergence from those of Ayres[4] and the microwave measurements of Brown[6] *et al.* The value of $\alpha/p$ at $E/p = 15$ V./cm./mm. mercury is almost two orders of magnitude smaller than that obtained by Ayres. It should be pointed out, however, that the measurements of Ayres[4] in nitrogen are greater by a number of orders of magnitude at low $E/p$ than the more recent results of Masch[7], Posin[8] and Dutton *et al.*[3].

It is of particular interest that, over the range of $E/p$ studied, the results are in very good agreement with the calculations of Emeléus, Lunt and Meek[9], which are based on the assumption of a Maxwellian distribution of electron energies.

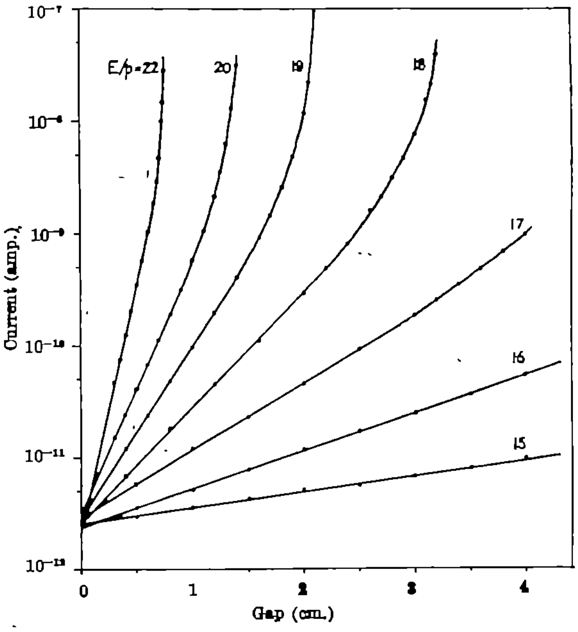

Fig 1. Hydrogen at pressure of 700 mm. of mercury and temperature of 20° C.

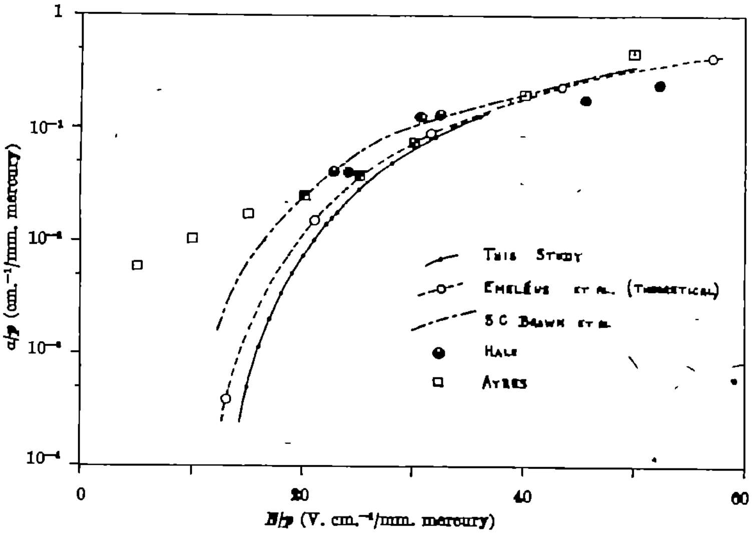

Fig. 2

Assuming the Townsend-type equation

$$i = i_0 \frac{\exp \alpha d}{1 - \gamma (\exp \alpha d - 1)}$$

to describe the form of the $d$ — ln $i$ plots, values of $\gamma$ have been evaluated for each experimental point on the non-linear part of the curve, and reasonably consistent values are obtained for all points on any one given curve. When these values of $\gamma$, together with the measured values of $\alpha/p$, are substituted into the Townsend equation, values of $pd$ at breakdown in good agreement with measured values are obtained.

If the measured values of $\alpha/p$ are substituted into the streamer equation in order to calculate breakdown voltages, it is found that the streamer criterion is considerably in error, and that in fact the criterion is only satisfied when over-voltages of the order of 10 per cent are applied.

## Variation of Flow Birefringence with Stress

In flowing liquids in which the same mechanism (for example, network deformation in a polymer solution) gives rise to birefringence and to stress, it is reasonable to expect these to vary together when factors such as rate of shear and concentration of solute are altered. Birefringence and stress require, for their complete description, ellipsoids, and the question arises as to how these are to be compared. According to the simplest possible relation (in which the stress tensor is equal to a constant multiple of the refractive index tensor plus an isotropic tensor) the optic and stress ellipsoids have the same orientation, and the differences of principal axes of either ellipsoid are proportional to the differences of the corresponding principal axes of the other ellipsoid. Thus for coaxial ellipsoids, which we shall consider here, it seems natural to compare differences of principal axes.

In stationary laminar shear flow, the symmetry of flow ensures that two principal axes of each ellipsoid lie in a plane containing the direction of flow and the velocity gradient (Fig. 1). Using light rays normal to this plane, the difference, $\Delta n$, of principal semi-axes and the orientation, $\chi$, of the optic ellipsoid can be measured directly. A recently developed technique[1] enables one to measure the corresponding quantities $\Delta p$, $\chi$ for the stress ellipsoid in solutions of suitable consistency. Such optical and stress measurements have not yet been made on the same liquid, so for the present we shall use the assumption of coaxiality of the ellipsoids to calculate $\Delta p$, the difference of principal stresses, from the measured shear stress $\tau$ and the optical extinction angle $\chi$, using the relation

$$\Delta p = 2\tau \operatorname{cosec} 2\chi \tag{1}$$

known from plane stress analysis[2].

It is therefore to be expected that the ratio

$$\frac{\Delta n}{\Delta p} = \frac{\Delta n \sin 2\chi}{2\tau} \tag{2}$$

will have simple properties.

For Newtonian liquids, $\chi = 45°$ for the stress ellipsoid; hence $\sin 2\chi = 1$ and $2\Delta n/\Delta p = \Delta n/\tau$, which is the 'Maxwell constant' introduced in the early theory of Raman and Krishnan[3] for this case. Optical measurements also give $\chi = 45°$ for most liquids at low shear rates, but values less than 45° at higher shear rates. Similar results for the stress have been found recently[1] for various polymer solutions. This is consistent with the assumption of coaxiality.

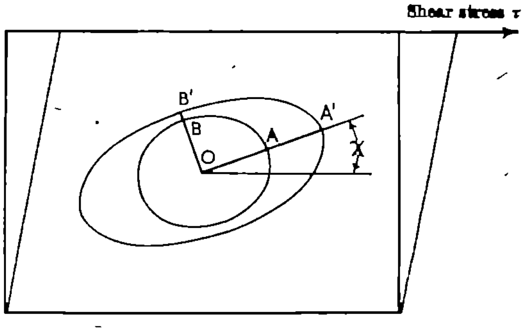

Fig. 1. Sections of coaxial optic ($AB$) and stress ($A'B'$) ellipsoids in shear flow. $OA - OB = \Delta n$; $OA' - OB' = \Delta p$

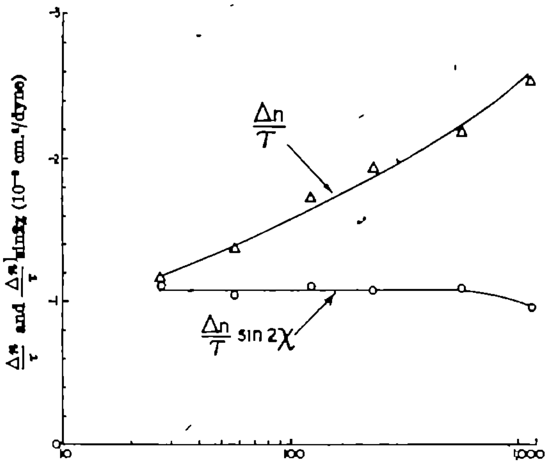

Fig. 2. Flow birefringence of polystyrene ('viscosity average' mol. weight, 200,000) in benzene; 6 per cent solution at 20° C. (Data of Signer, ref. 4)

Measurements of birefringence and shear stress have often been used[4] for calculating the ratio $\Delta n/\tau$ even when $\chi$ differs from 45°; but the ratio $\Delta n \sin 2\chi/\tau$ does not appear to have been calculated, despite the strong hint in this direction given by Buchheim and Philippoff[5]. Using published data[4,6] on moderately concentrated polystyrene solutions in various solvents, I have calculated this ratio and find that it is independent of shear rate, polymer concentration, and distribution of chain-length over considerable ranges of these variables. Moreover, the effect of omitting the factor $\sin 2\chi$, when significant, is deleterious: a striking example of this is given in Fig. 2. In these examples, the birefringence of the solvent is negligible in comparison with that of the polymer, so we take $\tau = G(\eta - \eta_s)$, the shear stress due to the polymer, where $G$ denotes shear rate and $\eta$, $\eta_s$ the solution and solvent viscosities.

Thus the data on certain polystyrene solutions are consistent with the view that the stress and optic ellipsoids are coaxial, that their orientation increases with shear rate, and that the difference of principal axes of the optic ellipsoid increases in proportion to the difference of the corresponding principal axes of the stress ellipsoid.

These results agree with a recent 'molecular' theory[7] in which stress and birefringence in a moderately concentrated flowing polymer solution are assumed to arise from network deformation; this theory leads to the results that the stress and optic ellipsoids are coaxial for any flow history at constant temperature, and that, in shear flow,

$$\frac{\Delta n}{\Delta p} = \frac{\Delta n \sin 2\chi}{2G\,(\eta-\eta_s)} = \frac{2\pi}{45}\,\frac{(n^2+2)^2}{n}\,\frac{\alpha_1-\alpha_2}{kT} \tag{3}$$

where $n$ denotes the mean refractive index of the solution, $k$ Boltzmann's constant, $T$ the absolute temperature, $\alpha_1$ and $\alpha_2$ the longitudinal and transverse principal polarizabilities of an 'equivalent random link' of the polymer chain. Kuhn and Kuhn have developed a theory for very dilute polymer solutions in which the deformation and orientation of polymer molecules are caused by hydrodynamic forces; using their expressions[8] for $\Delta n$, $\chi$ and $\eta$ for flexible molecules to calculate $\Delta n/\Delta p$, I find exactly the same equation (3).

This work forms part of the programme of fundamental research undertaken by the British Rayon Research Association.

## Oscillating Droplets and Spontaneous Emulsification

THE observations of Lewis and Pratt[1] and later of Lewis[2] on mass transfer and interfacial stability have led, at these authors' instigation, to our investigating the phenomena in greater detail.

We were able to produce an oscillation in a pendent drop of water in toluene by squirting acetone from a capillary at one side only of the drop. The arrival of the acetone at the interface immediately caused the drop to kick violently towards the capillary. This experiment was repeated with an air bubble in toluene and gave similar results. If, on the other hand, both water droplets and air bubbles are surrounded by a homogeneous solution of acetone in toluene, the water droplets oscillate; but the air bubbles show no movement whatever. An essential condition for oscillations thus appears to be a non-uniform distribution of solute around the drop; this may either be induced by squirting, as above, or by non-uniform diffusion across the interface. The effect of localized changes of interfacial tension resulting from variations of solute concentration around the drop can be deduced from the equation:

$$p = 2\gamma/r \tag{1}$$

where $p$ is excess pressure inside the drop, $\gamma$ is the interfacial tension and $r$ is the curvature of the surface of the drop. The equation shows that a sudden decrease in $\gamma$ over a given area will produce either an impulse outward through this area, or a decrease in $r$ for the same area. These expectations are in agreement with our experimental observations, and also those of Garner, Nutt and Mohtadi[3].

In an attempt to consider this phenomenon quantitatively, we have equated the localized interfacial energy changes to the potential energy of the pendent drop in its displaced position, and on this basis have derived the equation

$$M^*\left(\frac{dc}{d\gamma}\right)^* = \frac{A}{gh}\cdot\frac{c^*}{(1+\alpha)} \tag{2}$$

where $h$ is the height through which the centre of gravity of the drop rises during a kick and $c$ is the initial solute concentration in the phase from which diffusion occurs; $(dc/d\gamma)^*$ is the gradient of the (solute concentration)–(interfacial tension) curve at the point $c^*$. (The asterisks imply that the quantities correspond to a kick of size $h$.) Further, $M^*$ is the relative mass of the drop; $\alpha$ is the distribution

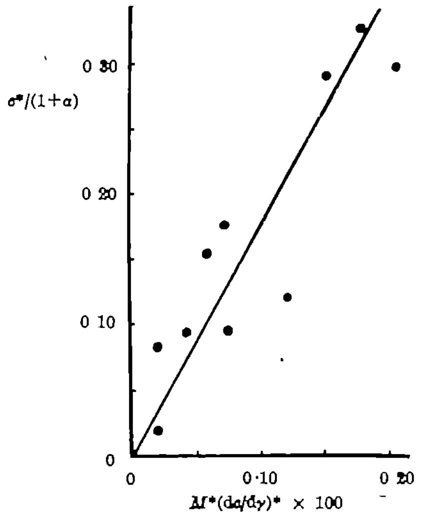

Fig. 1. Plot of $c^*/(1 + \alpha)$ against $M^*(dc/d\gamma)^* \times 100$ for various systems, each consisting of two phases with a third component soluble in both. All experiments were carried out at 20° C.

coefficient for the solute between the two phases and $A$ is the area over which a local change in $\gamma$ occurs.

By projecting the magnified image of the drop on to a screen, its oscillations were more easily studied and it was found possible to keep $h$ the same (and small) for each system. The factors $M^*$, $(dc/d\gamma)^*$, and $c^*/(1 + \alpha)$ were determined for each of ten different solute–solvent systems and $c^*/(1 + \alpha)$ plotted against $M^*(dc/d\gamma)^*$ (Fig. 1). Since the line is approximately linear, $A$ can vary very little from system to system. The presence of a detergent in the aqueous phase was found by Lewis greatly to reduce the violence of the oscillations, and in the present work 0·49 m$M$ sodium dodecyl sulphate increased $c^*$ considerably for the acetone-toluene/water system. The point $M^*(dc/d\gamma)^*$, $c^*/(1 + \alpha)$, for this case, however, did not lie on the line of the other results. A probable explanation is that the area $A$ over which the excesses of acetone spread was largely confined by the pressure of the detergent film. This aspect is being investigated.

Since increased transference-rates were observed by Lewis[2] for systems showing interfacial turbulence, investigations have been made on the basis of a suggestion by Quincke[4] that interfacial turbulence is the cause of spontaneous emulsification. If an emulsion were formed at the interface, the surface area would be increased and an increased rate of transference would be expected. Of the systems examined, only those containing alcohol visibly produced emulsions together with kicking of the interface. It is possible, however, to prevent the kicking by the addition of small amounts of protein or detergents without preventing the spontaneous emulsification. The conclusion is, therefore, that spontaneous emulsification is not related to kicking and proceeds according to the mechanism proposed by McBain and Woo[5]. This involves the idea of a column o diffusing alcohol carrying with it some oil int the water and there stranding it in the form o small droplets. Retardation of the diffusion-rate b the addition of sodium chloride to the aqueous phas confirms this, in that much less emulsion is formed Photographs and slow-motion ciné-films are bein taken demonstrating these effects.

Thanks are due to the Atomic Energy Authorit for financing the work and to Dr. J. T. Davies Mr. T. V. Davies, Mr. J. B. Lewis and Sir Eric Rideal for helpful discussions.

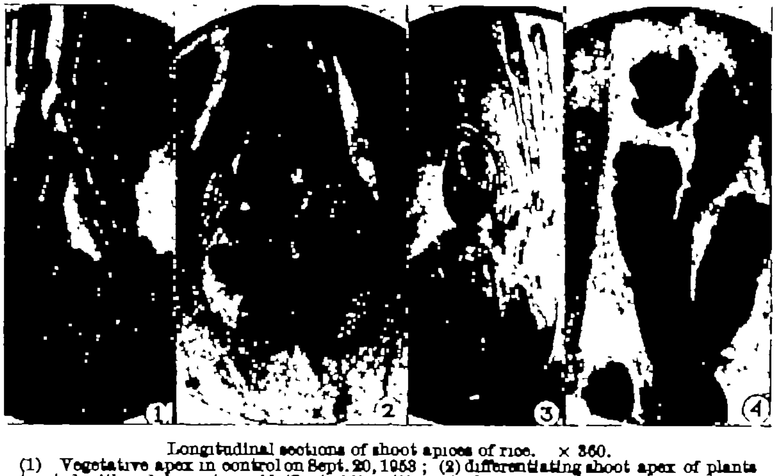
## Effect of Auxins on the Flowering Behaviour of Rice

IN a recent paper, Hussey and Gregory[1] reported that in two experiments out of four carried out, low concentration of auxin increased the number of flower primordia, while high concentration decreased it in winter barley. These results confirm the findings of Leopold and Thimann[2] in winter barley; but in petkus rye the flowering behaviour was not affected by the auxin treatment. In discussing these results, Hussey and Gregory defined the meaning of flower initiation and promotion of flowering, and expressed the opinion that auxin had no effect on the initiation of flowering, as auxin injection in an unfavourable photoperiod did not show initiation of flower primordia.

In rice, a different picture is obtained. Rice seeds, var. Rupsail, were sown on July 13, 1953, and 500 p.p.m. indole acetic acid and 300 p.p.m. α-naphthalene acetic acid were sprayed to the plants daily for one week from September 10. At the end of the treatment, the plants were allowed to continue



Longitudinal sections of shoot apices of rice. × 360.
(1) Vegetative apex in control on Sept. 20, 1953; (2) differentiating shoot apex of plants treated with indole acetic acid (Sept. 21); (3) control on Sept 25; (4) differentiation (Sept. 25) of flower initials of plants treated with indole acetic acid

e 1. Effect of Auxins on Leaf Number, Ear-Emergence, Ear-length and Number of Spikelets on the Main Shoot. Sowing Date, July 13, 1953. Replications, 15

| Treatment | No. of leaves | No. of days from sowing to ear-emergence | Ear-length (cm.) | Total No. of spikelets | No. of empty spikelets | No. of grains set per ear |
|---|---|---|---|---|---|---|
| ndole acetic acid (500 p.p.m.) | 15·2 ± 0·33 | 95·9 ± 2·72 | 6·76 ± 0·53 | 65·1 ± 2·25 | 34·3 ± 2·88 | 29·4 ± 1·52 |
| Naphthalene acetic acid (900 p.p.m.) | 15·6 ± 0·36 | 104·6 ± 2·80 | 5·90 ± 0·48 | 54·9 ± 2·18 | 36·0 ± 1·95 | 19·4 ± 1·66 |
| ontrol | 17·4 ± 0·37 | 123·0 ± 1·60 | 6·95 ± 0·30 | 90·2 ± 1·88 | 22·2 ± 0·64 | 68 0 ± 1 62 |

der natural day-length, which is unfavourable to wering. Microtome sections were prepared to udy daily changes in the development of the shoot ex, the details of which have been described elsehere[3]. Up to the time of the hormone spray, the oot apices in all the cases were vegetative. On ptember 13 the first sign of a transitional stage egan to appear in the plants treated with indole cetic acid. The full differentiation of the apex in lants treated with auxin took place much earlier han those of the control (Figs. 1–4).

Table 1 shows that plants treated with indole cetic acid flowered an average of 27·1 days earlier, nd plants treated with naphthalene acetic acid re earlier by 18·4 days. The total number of pikelets was rather adversely affected by the treatent, while the differences in ear-length are not ignificant. It is evident that the treatment caused significant reduction in the percentage of grain etting.

Preliminary experiments with only one concentration, fairly high, show that flower primordia are initiated earlier; but the promotion of flowering as visualized by Leopold and Thimann in the formation of an increased number of flowers was not seen. An after-effect of auxin is increased sterility in the spikelets.

## Gene Control of Copper-Sensitivity in *Saccharomyces*

An extensive study of the adaptation of yeasts to copper by Prof. Joji Ashida and his associates[1] revealed that yeasts are trained to high concentrations of copper by a two-step process. On agar containing copper, they found that copper-sensitive yeast cells grew as a thin film which became spotted with brown colonies of copper-resistant cells. Cells which they selected from the brown colonies proliferated rapidly on transfer to a copper medium, producing dense brown subcultures. Studies by the Ashida group indicated that many factors affect pigmentation of the copper-resistant cells. They inferred that the ability to resist copper-poisoning could be transferred to sensitive cells by ribonucleic acid extracted from closely related resistant organisms, but not by ribonucleic acid from sensitive organisms. They showed that the difference between resistant and sensitive cells was clearly expressed in medium containing 1 m*M*/l. of copper sulphate. In the cultures of *Saccharomyces* tested by Ashida and his group copper-resistant variants did not arise without training; none grew rapidly on a copper medium without previous selection by the two-step process described above.

Eighteen cultures of the Carbondale breeding stock (a stock developed by the hybridization of six different species of *Saccharomyces*) were tested for resistance to copper in broth cultures. All but one were resistant. The medium was supplemented with 1 m*M*/l. of copper sulphate and contained 4 ml. of liquid yeast extract (Anheuser–Busch), 3·5 gm. of peptone, 1·0 gm. of magnesium sulphate, 2·0 gm. of potassium dihydrogen phosphate, 40·0 gm. of dextrose, 1,000 ml. of distilled water. The *p*H was adjusted to 5·5 in a Beckman *p*H meter. The conclusions of the Ashida group that 1 m*M*/l. is a satisfactory concentration for distinguishing copper-resistant from copper-sensitive cultures were confirmed. 4 ml. of broth containing copper was inoculated with 300–500 cells from a 24-hr. copper-free slant. The resistant cultures grew rapidly in the copper-broth, whereas the sensitives failed to produce perceptible growth in 24 hr. Stock cultures were maintained on copper-free medium, and transfers from the copper-containing medium were never used in the hybridization programme. Genetical analysis was confined to the single original gene-pair controlling copper-resistance and copper-sensitivity, and no attempt was made to discover if other gene pairs were involved in the control of copper-sensitivity, since more than one gene controlling the same phenotype cannot be used in a programme aimed at chromosome mapping.

The original sensitive culture was mated to a resistant culture and eleven asci were dissected and tested for sensitivity to copper. Two sensitive and two resistant cultures were obtained from each ascus, indicating that the character is gene-controlled. The hybrid (family I) was heterozygous for genes controlling mating type and galactose fermentation. Four families heterozygous for the gene-pair controlling resistance and sensitivity to copper, as well as for genes controlling mating-type, fermentation of galactose, sucrose and melibiose, and synthesis of proline, *iso*leucine, uracil and lysine, were analysed. The pedigree is shown in Fig. 1. No linkage between the gene-pair controlling sensitivity to copper and other genes was found. Regular segregation occurred in all asci for all the markers indicated except for one ascus in family III which produced three *iso*leucine-independent and one *iso*leucine-dependent clone, and one ascus in family IV which produced three uracil-dependent and one uracil-independent clone. In all, a total of fifty-seven asci were analysed. In eight asci only three spores survived and the composition of the missing spore was inferred. Hybrids homozygous for either sensitivity or resistance produce only progeny which resemble their parents in this respect.

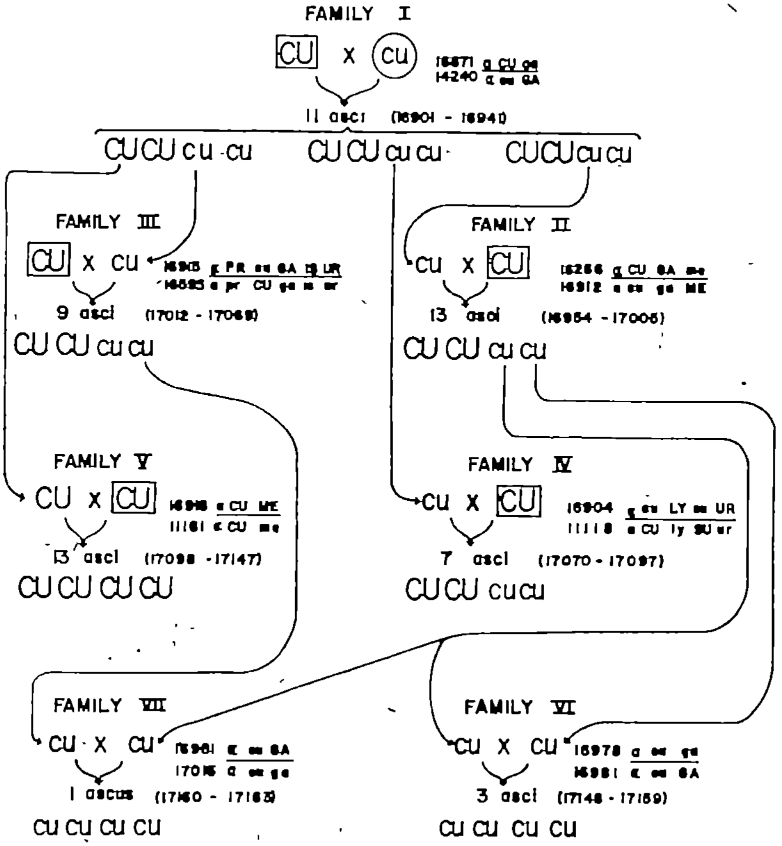

Fig. 1. PEDIGREES OF COPPER-RESISTANCE AND COPPER-SENSITIVITY
The designations enclosed in squares or circles indicate cultures selected by canvassing the breeding stocks. The genotypes of the hybrids and the serial numbers of the parent stocks are indicated to the right of each. The abbreviations are: *a/α*, mating type; *CU/cu*, copper sensitivity; *GA/ga*, galactose fermentation; *ME/me*, melibiose fermentation; *PR/pr*, proline requirement; *IS/is*, isoleucine *UR/ur*, uracil; *LY/ly*, lysine; *SU/su*, sucrose. The number of asci isolated from each hybrid and their serial numbers are indicated. Three asci from family I provided parent cultures for families II, III, IV and V as indicated by the arrows

## An Electrified Barrier for Caterpillars

PLANT-FEEDING caterpillars are often difficult to rear in the laboratory owing to their wandering habits. Cages which will contain the caterpillars, particularly in the young stages, must be of such fine mesh that the whole environment is altered and becomes unsuitable for both plant and insect. The wandering propensities of the insects are often accentuated by the unsuitable conditions. These difficulties have been overcome, in the case of the cutworm *Persectania aversa*, by the development of an electrified barrier. This bar
may be only two inches high
makes little alteration to the
vironment while effectively preve
ing the escape of the caterpills

The main difficulty in making
electrified barrier to contain sm
insects lies in the need to have
very narrow gap between the t
conducting elements. A sin
electrified wire close to the grou
is unsuitable, since any slight u
evenness in the soil surface w
cause a short-circuit. Short-circu
can be avoided by placing tv
conducting elements on a vertic
wooden or metal frame.

Aluminium foil, which is che
and easy to handle, is used for t
conducting elements. A strip
foil 2–2½ in. wide is glued to thic
brown paper. When dry it is c
into two strips; a guillotine is be
for this as it ensures that the edg
of the foil and paper are flush wit
each other over their whole lengt
The two paper-backed strips a
then glued to a wider strip of brow
paper so that one overlaps th
other by ¼ in. The two strips ar
thus insulated from each other b
one thickness of brown paper, bu
provide a barrier 1¾ in. wide. Th
whole completed barrier is then
glued to a wooden or metal fram
which is embedded in the soil o
the rearing container. The brown paper provides a gap small enough to stop the smallest caterpillars, but with sufficient insulation for the low voltages used.

Owing to this narrow gap, high voltages cannot be used. It would be necessary to determine the minimum voltage for each individual insect. For *P. aversa*, 6 V. is the lowest voltage which will stop the insects without killing them. The barriers in use at the moment carry 12 V. a.c. obtained by the use of a radio transformer. Direct current is less satisfactory, for although it will stop the caterpillars there is a tendency for many to stick across the two elements and be killed.

A vertical barrier is preferable, for the caterpillars can recoil more easily after making contact. Many of them drop straight back to the ground. On a horizontal barrier they are more likely to be killed by their inability to recoil quickly.

In addition to its use for preventing the escape of caterpillars, this barrier might be used to prevent them entering a control plot. In this case the electrified elements would need to be placed on the outside of the frame.

This equipment has not yet been tried with other insects. This will be done shortly, and a full description, together with methods of testing the barrier, will be published later.

## FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

### Monday, October 31

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 2.30 p.m.—Mr. H. D. R. Shearman: "The Technique of Ionospheric Investigation using Ground Back-Scatter" and "A Study of Ionospheric Propagation by means of Ground Back-Scatter"; Mr. R. W. Meadows: "An Experiment to Test the Reciprocal Radio Transmission Conditions over an Ionospheric Path of 740 km."; Mr. J. F. M. Laver and Mr. C. Stanesby: "An Experimental Test of Reciprocal Transmission over Two Long-Distance High-Frequency Radio Circuits". At .30 p.m.—Mr. W. J. Bray, Dr. J. A. Saxton, Mr. R. W. White and Mr. G. W. Luscombe: "V.H.F. Propagation by Ionospheric Scattering and its Application to Long-Distance Communication".

### Monday, October 31—Thursday, November 3

Society of Chemical Industry, Pesticides Group (in collaboration with the Association of British Insecticide Manufacturers, the British Agricultural Contractors' Association, the National Association of Corn and Agricultural Merchants, and the National Farmers' Union, at Eastbourne)—National Crop Protection Conference—"Practical Aspects of the Use of Insecticides and Fungicides in Agriculture and Horticulture".

### Tuesday, November 1

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Hannah Steinberg: "Drugs and Psychological Time".*

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. M. M. Swann: "Physiology of Mitosis". (Second of fifteen Lectures on "The Scientific Basis of Medicine.")*

### Wednesday, November 2

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. D. V. Ager: "The Geographical Distribution of Brachiopods in the British Middle Lias"; Dr. J. H. James: "The Structure and Stratigraphy of Part of the Pre-Cambrian Outcrop between Church Stretton and Linley, Shropshire".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. F. N. David and Dr. N. L. Johnson: "Some Tests of Significance with Ordered Variables".

University of London (in the Senate House, Malet Street, London, W.C.1), at 5.30 p.m.—Sir David Brunt, F.R.S.: "Retrospect and Prospect in Meteorology" (Meteorological Office Centenary Lecture).*

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. T. M. Harris: "Mesozoic Plants". (Further Lectures on November 9 and 16.)*

Institution of Electrical Engineers, London Graduates and Students Section (at Savoy Place, London, W.C.2), at 6.30 p.m.—Dr. E. Colin Cherry: "Communication of Information—Human, Animal and Machine".

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "The Evaluation of Anti-fungals".

British Psychological Society, Social Psychology Section (in the Psychology Department, Birkbeck College, Malet Street, London, W.C.1), at 7.30 p.m.—Symposium: "Who Doesn't Answer". A symposium on the problem of bias through non-return in questionnaire surveys and follow-up conducted by post.

### Wednesday, November 2—Friday, November 4

British Institute of Management (at Harrogate)—National Conference—"The Impact of Science on Management in the Future".

### Thursday, November 3

Royal Society (at Burlington House, Piccadilly, London, W.1, at 4.30 p.m.—Mr. H. G. Thornton, F.R.S.: "The Ecology of Micro-organisms in Soil" (Leeuwenhoek Lecture).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. H. Graham Cannon, F.R.S.: "What Lamarck Really Said!".

Mineralogical Society (in the apartments of the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

University of London (in the Barnes Hall, Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 5 p.m.—Lord Adrian, O.M., F.R.S.: "The Action of the Mammalian Olfactory Organ" (Semon Lecture).*

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Captain C. F. Booth and Mr. B. N. MacLarty: "The New High-Frequency Transmitting Station at Rugby".

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. H. G. Davies: "The Use of the Interference Microscope in Biological Research". (Third of fifteen Lectures on "The Scientific Basis of Medicine.")*

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

### Friday, November 4

Association of Applied Biologists (in the Meeting Room of the Royal Entomological Society of London, 41 Queen's Gate, South Kensington, London, S.W.7), at 11 a.m.—Meeting on "Some Recent Researches on Fruit Growing".

University of London (at Charing Cross Hospital Medical School London, W.C.2), at 5 p.m.—Dr. J. Hammond: "Growth in Animals".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Graham Sutton, F.R.S.: "Weather Forecasting—the Future Outlook".

---

## APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physical or Industrial Chemists or Chemical Engineers (with good honours degree or equivalent qualifications, preferably with experience), for research in the processing of coal and allied materials covering a wide field of physical chemistry and chemical engineering, including laboratory investigations into the surface characteristics and associated properties of coal and allied materials, and the design and operation of pilot plant—National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting 88/93 (November 4).

Biochemist, senior grade (with B.Sc. degree and/or A.R.I.C. and with wide general experience in medical biochemistry)—Group Secretary, Group 20 Hospital Management Committee, Stoney Stanton Road, Coventry (November 5).

Lecturer or Assistant Lecturer in Anatomy—Registrar, The University, Manchester 13 (November 7).

Senior Lecturer and Lecturer (with good honours degree and preferably with teaching experience) in Physics at the Nigerian College of Arts, Science and Technology—Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (November 7).

Research Assistant (with a good honours degree in biochemistry or in chemistry and physiology) in the Pharmacology Department—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (November 11).

Assistant (with interest in algology) in Botany—The Secretary, The University, Aberdeen (November 12).

Assistant Economist (with a university degree in economics, and preferably with postgraduate experience) at the Colonial Office, for duties including the review of economic trends and progress, economic analysis of colonial development plans, economic intelligence, research studies and to provide advice and assistance in economic fields to other departments of the Colonial Office—London Appointments Officer, Ministry of Labour and National Service, 1–6 Tavistock Square, London, W.C.1, quoting AC.1218 (November 12).

Chair of Zoology—The Registrar, University College, Singleton Park, Swansea (November 12).

Computer (with at least G.C.E., including mathematics at advanced level) in Mathematical Statistics and some Applied Mathematics—The Registrar, King's College, Newcastle-upon-Tyne (November 12).

Engineering Assistant (graduate, with at least two years practical experience of civil engineering work) in the Highway Planning Section, for duties in connexion with the realignment of roads, preliminary reconnaissance of new major highway routes and the control of main roadside access—County Planning Officer, Litton Lodge, Clifton Road, Winchester (November 12).

Lecturer in Physiology—The Dean, St. Bartholomew's Hospital Medical College, West Smithfield, London, E.C.1 (November 12).

Lecturer in Psychology—The Secretary, The University, Aberdeen (November 14).

Scientific Officer (with first- or second-class honours degree in chemistry or chemical engineering, or equivalent qualification, with wide interest in the application of science rather than in academic research, a broad appreciation of the scientific aspects of industrial problems and an aptitude for dealing with people, preferably with industrial experience) at the Headquarters Intelligence Division, Directorate of Scientific and Industrial Research, London, to collect and collate information, both from literature and personal visits, on technical developments of current importance—Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.620/54 (November 14).

Aerodynamicists and Mathematicians, Scientific Officer grade (with first- or second-class honours degree or equivalent qualification, preferably with some research or development experience), at Ministry of Supply Experimental Establishments, mainly at Amesbury, Farnborough, Bedford and London Headquarters, for research and development work on aircraft projects, problems of auto-control, flight test and performance analysis, guided weapons and gas turbines—Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.753/5A (November 15).

Lecturer or Assistant Lecturer in Geography at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 15).

Lecturer in Pharmacology—The Registrar, King's College, Strand, London, W.C.2 (November 15).

Scientific Officer (with an honours degree in chemistry with postgraduate experience in agricultural chemistry or an honours degree in agricultural chemistry) in the Chemical Research Division, Ministry of Agriculture, Northern Ireland, to take part in research investigations and the general duties of the Division, and possibly to undertake teaching duties in the Faculty of Agriculture, The Queen's University—Director of Establishments, Ministry of Finance, Stormont, Belfast, N. Ireland (November 16).

Physiologist or Biochemist (with an honours degree in science or equivalent qualification with physiology or biochemistry as major subject and preferably with postgraduate research experience in the fractionation and biological assay of protein hormones) as Research Officer at the Sheep Biology Laboratory, Prospect, N.S.W., Australia, to undertake investigations on the endocrinology of wool growth—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 205/36 (November 19).

Plant Physiologist (with an honours degree and postgraduate training and experience in plant physiology)—The Director, Tea Research Institute of Ceylon, St. Coombs, Talawakelle, Ceylon (November 19).

Senior Lecturer or Lecturer in Bacteriology—The Registrar, The University, Manchester 13 (November 19).

Senior Lecturer in Physics at Victoria University College, Wellington, New Zealand—Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 21).

Research Officer (with a first- or good second-class honours degree with qualifications in agricultural chemistry and experience in field experimentation) at Dunholme Field Station, Lincoln, to organize a series of field experiments on the manuring of sugar beet—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (November 26).

Director of the West African Institute of Social and Economic Research, University College, Ibadan—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1 (November 30).

Fellow and Senior Research Fellow (to undertake research in mathematical statistics or its applications, including mathematical genetics) in the Department of Statistics, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 30).

Lecturer in Applied Mathematics at St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (November 30).

Lecturer (with an honours degree in geography and with special qualifications in physical and economic geography and geomorphology) in Geography, at St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (November 30).

Lecturer or Assistant Lecturer (preferably with special interest in petrology, mineragraphy or structural geology) in Geology, at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 30).

Reader in Geology—The Registrar, University of Dacca, Ramna, Dacca, East Bengal, Pakistan (November 30).

Demonstrator (graduate in chemistry) in Chemistry—The Registrar, College of Technology, Manchester 1 (December 1).

Senior Lecturer (with a degree in science or engineering with geology as a major subject, and with field experience in mining and/or engineering geology, preferably with experience in mineragraphy and/or geophysical exploration) in Geology, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 2).

Lecturer (with a research degree in organic chemistry and experience of teaching this subject) in Organic Chemistry at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 9).

Chair of Building Science—The Registrar, The University, Liverpool (December 10).

Chair of Geography at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 15).

Stanley Elmore Research Fellowship in Extraction Metallurgy, to undertake research in the Department of Metallurgy of a University or similar Institution in the United Kingdom—Stanley Elmore Trust, 175 Temple Chambers, Temple Avenue, London, E.C.4 (December 31).

Assistant Trials Officer (with a degree in botany or agriculture or equivalent qualification, and with practical experience in crop production) at the Seale-Hayne Agricultural College, Newton Abbot—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Chemical Engineer (with a degree in chemical engineering or equivalent qualifications) on the personal staff of the Chief Engineer, North Thames Gas Board, for duties including development work, particularly in relation to new and improved methods of production, refining and distribution of gas from gaseous and liquid hydrocarbons and coal—Staff Controller, North Thames Gas Board, 30 Kensington Church Street, London, W.8, quoting 666/282.

Editing Librarian to be responsible for the handling, cataloguing and storage of film material—Films Officer, British Transport Commission, 25 Savile Row, London, W.1.

Entomologists (with an honours degree in zoology and training in entomology) in the Department of Tsetse Control, Gold Coast, to investigate various aspects of the bionomics and ecology of tsetse flies in relation to man and animals, and to supervise control measures under the Director of Tsetse Control—Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.77/13/01.

Senior Experimental Officer or Experimental Officer (with at least H.S.C. Science or equivalent qualification, with a general scientific and engineering background and a working knowledge of radioactivity measuring apparatus, remote handling, health physics, machine shop and experimental construction of equipment) in the Isotopes Division, for duties including the preparation of materials and the arrangement of irradiations with Pile Groups, high-level remote handling and measurements, developments of techniques and mechanical, electrical and electronic equipments—Establishment Officer, United Kingdom Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 2/103/409.

Senior Instructor (with academic qualifications and sound workshop training and with teaching experience) at the Staff Training College, Derby, to prepare, supervise and take part in courses of instruction for various grades of staff who will be engaged in designing, maintaining and repairing locomotives and rail-cars having dies engine propulsion with hydraulic, mechanical, electrical or oth transmission and control—Manpower Adviser, British Transpo Commission, 222 Marylebone Road, London, N.W.1.

Senior Scientific Officer (honours graduate with a sound knov ledge of statistical methods and preferably with industrial and technic experience) for work including research into problems connected wit the coking industry, preparation of technical reports and possib participation in operational research in the provinces; Scientific Officer (graduate with some industrial and/or technical experienc for general technical duties and the preparation and editing of tech nical reports—The Secretary, British Coke Research Associatio 74 Grosvenor Street, London, W.1.

Training Manager (honours graduate with qualification in physic or chemistry or Associate Member of a senior Engineering Institutio for the United Kingdom Atomic Energy Authority, Industrial Grou Capenhurst Works, for training activities within the works with th assistance of a small staff, and to maintain close liaison with loc Education Authorities and Technical Colleges—Recruitment Office U.K. Atomic Energy Authority, Industrial Group Headquarter Risley, near Warrington, quoting 1,132.

# USE AND ABUSE OF ENGLISH IN SCIENCE

EXPOSITION by the spoken or the written word is a skill which is not easily acquired; and dging from the adverse comments made on the forts of scientific men for many years past, they ave been particularly unfortunate in this field. Yet little reflexion will show that they are not alone in nding difficulty in conveying to others, even those f similar interests, their thoughts and views. So far s writing is concerned, the acknowledged masters pend a life-time practising their art. Such skill, artly a natural gift and partly acquired, is given to ew; but that is no reason why others should not trive to set down their thoughts in clear and pleasing erms.

Scientific men have a double task: they have to escribe their work to laymen and also to other cientists—sometimes those working in very different elds. Yet this task is not really a double one; there s fundamentally only a difference of emphasis. The ame qualities of clarity, simplicity and accuracy are till of major importance.

In an article on p. 851 of this issue of *Nature*, Dr. John R. Baker takes scientific men to task specifically for the way in which their papers are written and are presented. Thus he is narrowing down the general ssue, though it could be expected that any improvement in this particular respect would quickly have beneficial effects elsewhere. It is, of course, by no means a novelty to complain that many scientific men write in an uncouth and slovenly style; that complaint has been a common topic of discussion by directors of research for many years. It was indeed a factor in the discussions at the older universities a few years ago on the desirability of retaining at least one of the ancient languages in the entrance requirements. The argument was that, quite apart from any possible usefulness of the fleeting acquaintance with the classics and ancient history thus acquired, there was considerable value in the discipline of translation and the knowledge of the meaning of words and their roots which were acquired. Whether or not a limited knowledge of Latin and Greek is beneficial from this point of view, it is worth noting that the university members of the Committee of Vice-Chancellors and Principals in the recent report on university entrance requirements still commented on the inadequate command of English shown by many of those seeking to enter a university. This topic was also mentioned by Dr. R. P. Linstead in his recent inaugural address as rector of the Imperial College of Science and Technology.

Some specific points are, however, made by Dr. Baker which merit immediate consideration. After mentioning grammatical errors, he turns to what he terms "grandiloquence". Here, in passing, attention may be directed to the letter by Prof. H. N. Barber n *Nature* of October 15, p. 750, which surely needs no comment. It will, of course, be agreed that where certain terms or phrases have a specific technical meaning, they must be used. Even so, it is not a bad thing to consider from time to time whether their continual use in the course of perhaps a single paragraph, however justifiable on the grounds of accuracy, does not lay the writer open to the charge of using technical jargon. It is clearly a point on which a certain amount of thinking is necessary.

On the question of the use of a German construction for the sequence of adjectives and nouns, Dr. Baker is probably right in stating that the practice is growing. In some cases—and Dr. Baker quotes examples—only the judicious use of the occasional hyphen can save a phrase from meaning the reverse of what is intended; the meaning may still be obvious from the context, but it should not be necessary to have to go to the context in such short phrases. It is difficult to find any real justification for the use of this style. To a limited extent it may give crispness to a statement and save the use of the word 'of'; but its general adoption seems dangerous and unnecessary. Dr. Baker's examples could readily be multiplied, and point to the growth of a new style in scientific writing which has nothing to commend it.

Passing now beyond Dr. Baker's article, reference may be made to another tendency—perhaps it is only a mannerism—which has been noticed in recent years, namely, an unusual use of some common verbs. Thus an author may write that he "reacted zinc with hydrochloric acid", or he "combusted" something, or that "a metal distorts upon cooling", or that "a wave propagates in a straight line". Such phrases are frequently seen in communications submitted to *Nature*, from Great Britain as well as elsewhere, and sometimes it is difficult to be sure whether or not a new technical meaning is being given to a hitherto common word. Unless some particular quality is intended by the use of common words in this way, it would seem that an unnecessary grammatical change is being introduced. The English language, in spite of its lack of inflexions, is wonderfully fluid and surely does not need to be subjected to such twists in order to accommodate new terms or to re-express old ones.

Another problem which is causing increasing concern—to printers as well as to editors—is the frequent and indiscriminate use of abbreviations in the form of a single capital letter, or a group of capitals, to represent the name of a substance, or perhaps even an adjective or adverb. The printer is concerned because a page of text sprinkled with capital letters is not pleasing in appearance; and, like other craftsmen, he feels that his efforts are being frustrated. It may be argued that this is of no concern to the scientist; but surely his work is worthy of good presentation, and there is satisfaction and even advantage in recording the results of research in an elegant style.

So far as the use of abbreviations themselves is concerned, the subject was discussed some time ago in these columns. As was pointed out then, a little consideration will show that abbreviations can often be replaced by pronouns without loss of clarity or accuracy. No one writing for the general reader would willingly use the same noun several times in a single sentence; yet when abbreviations or symbols are adopted, there seems to be no hesitation in repeating them—often as many times as possible. Biochemists are great offenders in this respect, and their excuse must be that many of the substances they use have unwieldy names. Similarly, organic chemists are hampered by a cumbersome nomenclature, which however admirable from the point of view of describing a substance, invites the use of abbreviations; indeed, the industrial organic chemist has found it necessary to invent names or use specific symbols like DDT for the sake of the users of his products. But a sense of proportion must be maintained in devising and using specialized terms; thus it seems pointless to write *p*-ClHgBA for *p*-chloromercuribenzoate, and positively dangerous to use H for histidine. The habit—for it is little else—of introducing abbreviations is now spreading through physical chemistry to physics and to mathematics; indeed, to all sciences. Thus E has been used for 'enzyme', with the derived symbols ES for 'enzyme substrate' and ESI for enzyme substrate inhibitor, and M.O. for molecular orbital; and what is the physicist to think when he finds a plentiful sprinkling of the term MIT on a page, only to find on careful reading that it is an abbreviation for monoiodotyrosine and not the Massachusetts Institute of Technology? Then, again, can the use of ARG for autoradiograph be justified? Mathematical signs occasionally appear in a line of text, especially the sign for 'is equal to'. These examples are taken from manuscripts submitted to *Nature*, and many others might readily be quoted.

It may be claimed that, if an author writes out the name or term, followed by his chosen abbreviation, on the first occasion of its use, or includes a list of the abbreviations he proposes to use, then he is justified in employing his abbreviations throughout the remainder of that particular piece of writing. But is every scientific communication to have its own glossary? Consider the confusion—and additional space required—which would occur in a journal such as *Nature*, in which two dozen or so specialized communications appear every week. The fact is that these abbreviations are, in the main, laboratory and notebook shorthand, or even slang, very valuable in their proper place, but nevertheless a new language, which at present does not seem suited for the considered statement offered for discussion and appraisement by other workers.

The use of abbreviations, especially initial letters, is now becoming so fashionable among scientists that one suspects authors sometimes go out of their way to use them; for example, SV for seminal vesicle. With the increased sliding growth among the various disciplines of science, resulting in such departments of research as biochemistry and biophysics, this fashion may, if not checked, defeat its own ends and produce a veritable 'Tower of Babel'. Indeed, the time does not seem far away when hig school pupils will have to learn a new table of symbo apart from those atomic.

A further problem, which may not occur to mo writers, has to be faced in the preparation of a index. Abbreviations or initials sometimes occu alphabetically in quite a different position from tha which would be occupied by a full term, thus causin confusion during reference.

Dr. Baker begins his article by disclaiming an intention of setting himself up as a stylist; and i taking up various points he makes, and adding others we must make a similar disclaimer. Much of wha has been said is clearly a matter of opinion, an those holding strong views are unlikely to be converted. Nevertheless, the mode of presenting scientifi results has been criticized over a long period of years and it behoves scientists to give the matter carefu attention and to consider whether they can, by din of a little more care and thought, free *themselves* o the charge of talking and writing jargon. In th present age, the promotion and exposition of research can be almost as important as the work itself.

# SCIENCE AND THE HUMANITIES

## Science and the Human Imagination

Aspects of the History and Logic of Physical Science. By Dr. Mary B. Hesse. Pp. 171. (London: Student Christian Movement Press, Ltd., 1954.) 12*s*. 6*d*. net.

IT is surely one of the most significant features of our generation that not only are we contemporary with a flood of new scientific discovery which has already changed the pattern of our physical life, and is rapidly changing the pattern of our thinking, but we are also very conscious of the need to understand this strange new activity called science and to assess its real status and its relationship with other great movements of the human spirit. This little book by Dr. Mary Hesse, herself a mathematician in the University of Leeds, is an attempt to answer the questions: What is science? Is it something fixed and determinate, or is it variable and responsive to the thought-forms of its day? What right have we to say that science is a true account of the natural order? And how is the scientific method related to art and religion?

Dr. Hesse deals with these questions in two stages. First she describes the changing models of science, and shows how the tumultuous flow of new discoveries in physics, from the electron in 1897 to the new quantum theories of 1926, have made old models no longer tenable, and forced us to see what ought indeed to have been recognized all the time, that our models and concepts are, after all, only models and concepts the suitability of which to represent the inaccessible 'things-in-themselves' must be judged by each generation according to the criteria accepted at the time; they can never be final, and they always involve imagination and intuition. One of the most valuable sections of this part of the book is where the author urges a return to the old schoolmen's way of argument 'by analogy', supplementing our more conventional recognition of identity and difference. For argument by analogy involves us in an act of response to our environment wider and re generous than that which men of science have metimes claimed, and at the same time it joins m with the artist and the poet.

In the second half of the book, Dr. Hesse deals h the status of scientific theory. She is much racted to the operational view, according to which that we may rightly ask or expect of science is an swer to the question: What will happen to this if lo that? All explanations, or interpretations, are necessary, unprovable and probably meaningless! ith this in mind, she criticizes Eddington and Dirac cause many of their concepts are not definable in rms of direct measurement, and what they call servables' are by no means always observable. t the author admits that this will not do, for there an element of awareness in scientific work which akes us feel that we do indeed grapple with someing real, however inadequately it may be conveyed us in our current models.

In some ways this is the weaker half of the book, d it is hard not to feel that Dr. Hesse is still a tle uncertain in her own mind. Thus, when e comes to the end of the book and asks about possible synthesis of science and religion, all e can say is that "there is no satisfying synthesis . . this side of the Kingdom of God"; and hen she asks if any transcendental faith can be cepted with conviction in the modern world, she plies that the question must "remain unanswered ntil it comes spontaneously from the quality of life the Christian community". But surely the whole tivity of science is a silent witness to a transcendtal faith—in a reality so exciting that it comands our study, and so deeply other than us, at we never get beyond the world of model and ncept to represent it. I cannot myself escape the nviction that this part of the book would have een more convincing if more biology and less physics ere incorporated in it, and if more questions had een asked about man-the-scientist as well as those bout the nature of scientific studies. But this is a ery readable book, and a stimulating one, which ertainly carries the argument further than some of e other fairly recent popular expositions of science ave done. We can even excuse a few scientific accuracies in face of the extreme honesty of the hole approach, and the recognition that science, art d religion have each their part to play in the atisfactions of human living.

C. A. Coulson

# RECEPTORS AND SENSORY PERCEPTION

## eceptors and Sensory Perception

Discussion of Aims, Means, and Results of Electrohysiological Research into the Process of Reception. Mrs. Hepsa Ely Silliman Memorial Lectures.) By r. Ragnar Granit. Pp. xii+369. (New Haven, onn.: Yale University Press; London: Oxford niversity Press, 1955.) 5 dollars; 40*s*. net.

AN indolent reviewer might claim that there is really no need for him to do more than direct ttention to the full title of this book. It is about 'Receptors and Sensory Perception", and it is the ubstance of the Silliman Lectures which Prof. agnar Granit gave at Yale in 1954. It is therefore n up-to-date presentation of one of the growingoints of neurophysiology, composed for a scientific, but not necessarily biological, audience by one who is an acknowledged expert in the field he has to cover.

Scientists ought not to need reminding of the quality of Silliman Lectures or of the debt which we all owe to the Silliman Foundation. It has induced a long list of the foremost investigators to emerge from their laboratories to put on record the general theme of their work. Some of the earlier books in the series, like those by J. J. Thomson and Rutherford, are now out of print; but most of them have been milestones. Some have been reprinted and have lost none of their impact, like Sherrington's "Integrative Action of the Nervous System"; but there can be very few of them which have not greatly influenced the progress of scientific work in the twentieth century.

Ragnar Granit's own contributions to the physiology of vision have been a constant inspiration for many years, and he has already brought them together in 1947 in his book on the retina. Here, however, they can be seen in less detail but in better perspective against the general background of sensory physiology. In the earlier chapters, for example, he gives an excellent account both of the older work on the discharge of impulses from sensory end organs and of the recent developments in the study of cutaneous receptors and the function of different kinds of receptor structure and peripheral nerve fibre. Zotterman's recent work on thermoreceptors is well described, and, if we are still left in doubt about the nervous mechanism of pain, it is not Granit's fault that the evidence is still incomplete.

The chapters on the nervous organization of the retina will naturally be read with the greatest attention by all who are concerned with the problem of colour vision, and they will find a clear statement and defence of Granit's dominator–modulator theory. For the general physiologist, however, the concluding chapters on the muscle receptors are perhaps the most interesting, for here we can see how even the most straightforward kind of receptor is subject to a constant adjustment by the central nervous system to make it provide the right kind of information.

In fact, it is not praising Granit's book too highly to say that it is a worthy contribution to the series of Silliman Lectures.

Adrian

# INTERNATIONAL CO-ORDINATION OF GALACTIC RESEARCH

## Co-ordination of Galactic Research

Edited by A. Blaauw. (International Astronomical Union Symposium No. 1, held at Groningen, 22–27 June, 1953.) Pp. viii+59. (Cambridge: At the University Press, 1955.) 7*s*. 6*d*. net.

RESEARCH into the nature of the stellar system in which we live has always formed a very considerable part of astronomy; but during the past ten years notable advances arising from a number of new techniques and ideas have greatly stimulated interest in this field. Among the new techniques radio astronomy has had resounding success, especially in dealing with interstellar matter, and is still producing a great flow of important new results. It is true that many of the radio observations have as yet no clear interpretation, but we believe that we now have the tools to map the spirals of the Milky Way, and to gain great insight into the dynamical structure of the whole system. Simultaneously, the older optical methods have been strengthened by the use of Schmidt telescopes, especially with narrow-pass filters or objective prisms, bringing us a wealth of new data relating to both stars and interstellar material. Equally important improvements in other practical techniques, for example, in photoelectric photometry, are also playing a great part in galactic research.

There has in addition been a ferment of new theoretical ideas. Baade's suggestion that there are two distinct stellar populations in the Milky Way is growing into a more general concept of families of stars having as much as a thousand-fold range in life-times and reaching a corresponding variety of stages in evolution, whether viewed as individual producers of energy from nuclear sources or as particles in the general dynamics of the galaxy. That graveyard of stellar evolution theories, the Hertzsprung–Russell diagram, has now assumed greater significance and greater complexity than ever before. Undismayed by the revelation of these and other complications, theorists are pressing on with their studies of stellar interiors, attempting to compute the evolutionary changes to be expected in stars as a result of the burning of hydrogen or other nuclear fuels.

Concurrently with rapid advances in our knowledge of the Milky Way system and of similar nearby systems such as the Andromeda spiral nebula *M*31, there has been a proliferation of new problems urgently needing investigation. But there has been little increase in the available labour force to deal with these; indeed, an insatiable demand for young scientists from other subjects has made it increasingly difficult to maintain the supply of competent astronomers even at its present modest level. In a situation of too many problems and too few astronomers, one method is to restrict attention to the more outstanding problems and to proceed as far as possible by a careful, but very limited, sampling of the sky. One of the chief purposes of the conference reported in this volume was to discuss ways by which this could be done.

The conference was organized by a sub-committee of the International Astronomical Union's Commission on Stellar Statistics and was largely inspired by Prof. J. H. Oort, himself one of the leading authorities on galactic research. The report gives a very useful summary of work in progress at the date of the meeting, June 1953, and many suggestions for the more urgent programmes of further research. It confines itself for the most part to the standard techniques of optical astronomy, studies of variable stars, photometric measurements of various kinds, spectrum classification, proper motions, radial velocities, etc.

This is one of the first astronomical books in which the term 'man-hours' occurs, in my opinion a belated appearance. Observational astronomy is peculiar in the enormous numbers of objects requiring investigation and the slowness with which the desired information can be collected. A great deal of the work now waiting to be done might quite well have been started thirty years ago, and the need was doubtless in part already understood then. The chief reason why so much has not yet been properly begun is the same reason why the *Carte du Ciel* has never been finished: there is a lack of man-power for routine work which requires persistence and precision above the ordinary, but can sometimes be tedious and dull, which gives results of essential importance but nevertheless brings little thanks or recognition from the scientific community. Looki at twentieth-century astronomical history, o wonders how many of the programmes suggested this report will be completed in thirty years time.

The widespread use of automatic machinery industry and its appearance in other fields of scienti research have turned the thoughts of some astronome to its application to routine astronomical programme In principle, this seems quite possible; but as eve engineer knows, there is a very long step from designi a machine in principle to bringing it into successf and reliable operation. Not all astronomical pr grammes could be attacked in this way, and eve successful machinery would have serious limitation but we may be forced to a choice between an adequa volume of machine-made results or next to no resul at all. The conference, however, appears to ha stuck to well-established methods and to have give little thought to such developments.

I must confess to some pessimism with regard t our ability to finish urgent tasks in galactic researc by existing methods, but nevertheless can strongl recommend this volume to anyone seriously intereste in Milky Way problems. It should be compulsor reading for British optical astronomers, the gre majority of whom have in recent years tended to lo touch with this important branch of their subjec despite the notable achievements of their radi colleagues.

R. O. Redman

# MATHEMATICAL TABLES OF THE NATIONAL BUREAU OF STANDARDS, WASHINGTON

United States Department of Commerce: Nation
Bureau of Standards

Tables of Functions and of Zeros of Functions Collected Short Tables of the National Bureau o Standards Computation Laboratory. (Applied Mathematics Series—No. 37.) Pp. x+211; 2.25 dollars.

Table of Salvo Kill Probabilities for Square Target (Applied Mathematics Series—No. 44.) Pp. ix+33 30 cents.

Tables of the Error Function and Its Derivative (Applied Mathematics Series—No. 41.) Pp. xi+302 3.25 dollars.

(Washington, D.C.: Government Printing Office 1954.)

THE first of these three volumes brings togethe eighteen short tables of functions and of zeros o functions, most of which have appeared before i various periodicals, three only being new publications Among others, it contains the integrals of the tw Bessel functions of zero order over ranges from 0 t 8·50; $\int_1^\infty e^{-xu}u^{-n}du$, $x$ ranging from 0 to 10 and $n$ fron 0 to 20 through integers; Struve functions; Fourie coefficients up to order 100 of powers of $x$ up to $x^{10}$ sines and cosines for radian arguments between 10 and 1,000; and $x^n/n!$ for $x$ up to 10 and $n$ up to 40 i integers. As regards the tables of zeros, there ar included those of the Legendre polynomials of orde 1–16, the first fifteen Laguerre polynomials, Besse functions of simple fractional orders, and thei derivatives, and the first ten complex zeros of sin $z-z$ Explanatory formulæ and bibliographical reference are given in all cases.

The second volume, "Table of Salvo Kill Probabilities for Square Targets", contains thirty-three pages devoted entirely to the tabulation of a single probability function defined as a double exponential integral extended over a square. It is considered as a function of five independent parameters, each of which has several representative selected values, the first being the number of missiles released in salvo up to a maximum of two hundred, and the others being concerned with the dispersion and the assumed lethal probability of a single missile. The significance of these parameters is explained in detail in the introduction.

The third work, "Tables of the Error Function and its Derivative", is of considerable extent and first appeared in 1941 under the title of Mathematical Table 8. Apart from a short subsidiary section, it is entirely concerned with the tabulation of the normalized error-function

$$\frac{2}{\sqrt{\pi}}\int_0^x \exp(-\alpha^2)d\alpha$$

and its derivative $\frac{2}{\sqrt{\pi}}\exp(-x^2)$.

All the entries are to fifteen decimal places, and the ranges of $x$ are 0 to 1 at intervals of 0·0001, 1 to 5·6 at intervals of 0·001, and a few subsequent values between 5·6 and 6. In the last range the differences between the two functions and 1 and 0, respectively, are of course extremely small, affecting only the fourteenth and fifteenth decimal places. In the short supplementary table (previously mentioned), these differences are given to eight significant figures for $x$ between 4 and 10 at 0·01 intervals with their appropriate inverse powers of 10, the last of which is $10^{-45}$. Eleven pages of introduction include details of the methods used in computing and checking the tables and a bibliography.

J. H. PEARCE

# PHYSIOLOGY IN COLD CLIMATES

## Man in a Cold Environment

Physiological and Pathological Effects of Exposure to Low Temperatures. (Monographs of the Physiological Society—No. 2.) By Prof. Alan C. Burton and Prof. Otto G. Edholm. Pp. xiv+273. (London: Edward Arnold (Publishers), Ltd., 1955.) 30s. net.

THIS book on the "Physiological and Pathological Effects of Exposure to Low Temperatures" has been written under the joint authorship of a biophysicist and a physiologist, and is the second of a series of monographs of the Physiological Society. The authors are to be congratulated on making readily available for the first time information largely derived from research carried out for the Armed Services. During and just after the Second World War a very considerable amount of literature accumulated, which the authors have examined and presented in a very readable form, together with the conclusions which they have drawn with great care and restraint from the varying points of view. There are both author and subject indexes, and at the end of each chapter very full references are given. The text is admirably illustrated with charts and diagrams. The first part of the monograph deals with the physical laws governing the interchange of heat between man and his environment. Towards the end of this section the authors make the important point that "In almost every case of the general problem of enabling men to survive and function efficiently in adverse environments as at high altitude, the answer to the problem proved to be in the field of engineering, rather than in modifying human physiology"; however, "the engineering answer is not perfected without the fundamental knowledge of the underlying physiology".

The next three chapters discuss the insulation afforded by the air, the clothing and the tissues of the body. Man has been able to extend his sphere of activity both in hot and in cold climates by the use of clothes; but as yet no really satisfactory means of protecting the face has proved practical, and the exposed regions of the body play an important part in determining the 'tolerance time' of a particular clothing assembly. The chapter on the estimation of the thermal demand sets out the variables other than temperature that can affect the heat loss of the human body, and a 'unitary estimate' of these varying factors such as wind chill, corrected effective temperature, solar radiation, and radiation increment, can be introduced as a correction factor to the environmental temperature, and an estimate of the clothing requirements obtained from a single parameter. The chapter on the possibilities of maintaining a thermal steady state in the cold deals also with comparative physiology, and it is pointed out that "A survey of what methods of compensation are actually used by animals in cold environments is most useful, since it permits us to explore the possibilities of further exploitation of methods of compensation, which have not been fully utilized by animals".

Shivering is discussed under the heading of the metabolic response to cold. Recent work has shown that there is an increased 'thermal muscular tone' prior to the onset of shivering; but the question of extramuscular metabolic increments in response to cold is still open, as a great deal of evidence both for and against this increment has been produced. There is an increased voluntary dietary intake in response to cold; but so far no simple explanation of this response has been found to be tenable. Acclimatization to cold is considered under general bodily changes and local changes. There is some evidence against acclimatization to cold, and it would seem that any acclimatization sustained is only of short duration when compared with that in response to chronic exposure to heat.

Hypothermia, both chronic and acute, is discussed, and the consensus of opinion as regards the treatment of these conditions is that: rapid rewarming should be carried out in cases of acute hypothermia, and rapid rewarming with correction of the body fluid balance and administration of glucose for cases of chronic hypothermia; moderate rewarming is to be condemned. The various pathological changes taking place in response to local cold injury are discussed, and it is considered that "there is a great need for more detailed studies in this field which profitably could include more precise definition of the conditions necessary to produce mild injury".

The last chapter of the monograph very appropriately deals with problems for future research, and must act as a stimulus to those who are apt to think that this branch of climatic physiology lies dormant except in times of national emergency. The monograph is a valuable storehouse of information and should be read by everyone who is interested in the physiology of cold climates.

J. R. BROWN

## Michael Faraday

Man of Simplicity. By Prof. James Kendall. Pp. 196+4 plates. (London: Faber and Faber, Ltd., 1955.) 12*s*. 6*d*. net.

THERE is no resisting Prof. James Kendall. He begins at a disadvantage, for one picks up his book with the thought that this is another small book about Faraday, of which there are already rather too many. Then it is a little disconcerting to meet in the early pages a sentence such as this: "Humphry invited Michael to come to the Royal Institution for an interview". Despite the author's apology, this familiar mode of address of the two principal characters seems unnecessary, and it asserts rather oddly in passages where third persons, for example Wollaston, are accorded the more formal surname. There is, also, to one reader at least, some over-emphasis on the 'simplicity' of Faraday's nature. Simplicity and ingenuousness had their place in a complex character; but to stress them unduly is to give a false impression of the man as a whole.

Personal prejudices on points of this kind are, however, forgotten after a few chapters, and the reader finds himself swept along on the tide of Prof. Kendall's enthusiasm. The treatment of Faraday's scientific work does not pretend to be very full or comprehensive; but the story of his life is admirably and sympathetically told, the significance of the principal researches is brought out in the narrative, and the result is a very readable book. It is, incidentally, to anyone who has heard Prof. Kendall lecture on the subject, a delightful reminder of the lecturer.

## Atoms in the Family

My Life with Enrico Fermi—Designer of the First Atomic Pile. By Laura Fermi. Pp. 284+15 plates. (London: George Allen and Unwin, Ltd., 1955.) 18*s*. net.

ONE could wish that every great scientist had a wife with such literary skill and sense of humour as Mrs. Laura Fermi. Her book is much more than just a biography of her famous husband, the late Enrico Fermi, though naturally he is the chief person in it. It gives snatches from his childhood and from his life as a student and young professor, unpretentiously written against a background of the Italian scene and the rising of Fascism. From there the narrative moves to the United States and those—for her—most puzzling years 1939–45 in which Fermi, though still technically an enemy alien, moved about between New York, Chicago and Los Alamos on mysterious errands. Only when the atom bomb had blasted the veil of secrecy did Mrs. Fermi and the other wives of scientists find out that the first atomic pile had come into operation three years previously, and that Fermi had been one of the leading minds in that stupendous enterprise which resulted in Hiroshima and Nagasaki.

But Mrs. Fermi keeps an admirable balance between the great events around which her life had to shape itself and the small everyday things of which that life consisted. She is a good observer of people, and her pen-portraits are admirable. Many of the people I knew in Los Alamos have come to life again for me through her shrewd observations. Nor does that shrewdness desert her when it comes to describing her own husband. He lives in these pages as his friends knew him—admirable but not faultless, and likeable even in his faults.

Naturally, the book should not be considered as material for the historian, but practically all the scientific facts she quotes are correct (and, by th way, admirably presented for the non-scientist), ar I have found only a few minute and quite irreleva inaccuracies in the events she writes about. This a human, engaging and entertaining book, written a time when Fermi was still in good health, befo the illness which caused his untimely death soo afterwards.

O. R. FRISCH

## The Botany of Cook's Voyages and Its Unexpecte Significance in Relation to Anthropology, Bi geography and History

By Prof. Elmer Drew Merrill. (Chronica Botanic Vol. 14, Number 5/6.) Pp. iv+161–384+plat 80–92. (Waltham, Mass.: The Chronica Botanic Co.; London: Wm. Dawson and Sons, Ltd., 1954 4.75 dollars (cloth).

DR. MERRILL is a systematist and plant geo grapher of great seniority. In this curiou and uneven book he examines the herbaria collect on Captain Cook's first and second voyages. Hi main purpose is to decide to what extent there wa a diffusion of crop plants, weeds and cultures acro the Pacific Ocean between America and Asia befor Magellan's voyage in 1520. This is a problem whic has for a long time interested scholars, and it ha recently been popularized through the Kon-Tik expedition and the writings of T. Heyerdahl.

There undoubtedly is room for further critica discussion of the botanical evidence for and agains the early blending of American and Polynesia cultures. But such a discussion would need to b objective, urbane, and free from prejudices an polemics and innuendoes about the competence o other workers in the field. Dr. Merrill's book fulfil none of these requirements. One must only regret that in this book Dr. Merrill's knowledge and experi ence have been deployed in a manner which does no enlist the confidence of the reader nor illuminate th subject.

E. ASHBY

## Optics

By Arnold Sommerfeld. (Lectures on Theoretical Physics, Volume 4.) Translated by Otto Laporte and Peter A. Moldauer. Pp. xiii+383. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1954.) 6.80 dollars.

THE appearance in English of this part of Sommerfeld's lectures on theoretical physics is a very welcome addition to the literature. In Sommerfeld's course of lectures, theoretical optics formed an important section which does not correspond to any definite course in most British universities. In Britain the material, in so far as it is treated, would usually be found either in a course on electromagnetic theory in general, which would not allow time for detailed treatment of many optical problems, or in a course on physical optics, which usually includes less of the mathematical theory. This text by one of the masters in the mathematical treatment of wave problems will nevertheless be valuable for use with courses of both kinds and of great help to those who want to take optics further than the normal undergraduate teaching permits.

As in the other volumes, the use of powerful mathematical techniques is presented and applied without losing sight of the physical ideas behind them, or of the fact that one is dealing with knowledge which, in the last resort, is derived from experiment.

R. E. PEIERLS

# ENGLISH STYLE IN SCIENTIFIC PAPERS

By Dr. JOHN R. BAKER
Department of Zoology, Oxford

MANY scientific papers published in Great Britain are written in a style quite different from that adopted by good English authors. There would be no disadvantage in that, if an improved version of our language had been invented for cientific papers. This, however, is not so. For larity and directness one must turn to non-scientific authors. One hesitates to direct attention to this ubject lest one be accused of setting oneself up as a stylist. There is no such intention here. It is proposed merely to suggest a few ways in which cientific papers could be made simpler, clearer, and more pleasant to read.

To prevent any misunderstanding, it must be emarked at the outset that it is no part of my purpose to try to oppose the use of necessary scientific words. On the contrary, the precise use of certain technical terms, carefully defined and internationally understood, is an obvious necessity. We shall be concerned here with the words that stand between the technical terms.

If one examines all those passages in scientific papers that are least in accord with good English style, one finds that there are three main kinds of error, which may be described briefly as those of grammar, grandiloquence and German construction.

It would be absurd to treat the subject of grammar at any length here, since good advice on this subject is so readily available. Grammatical errors in scientific papers sometimes make it impossible to be sure what a sentence is intended to mean. In other cases the mistakes are troublesome only because they distract the reader's attention from the subject under discussion. The words ending in *-ing* (especially *using*) are very frequently misused. One repeatedly finds such statements as this: 'Examining a capillary under the microscope, after staining with carmine, it resembles a homogeneous hyaline tube'. Yet anyone who is intelligent enough to carry out scientific research at a university can easily grasp everything that it is essential to know about the use of present participles and gerunds in fifteen minutes.

The menace of grandiloquence seems to derive from the time when doctors used many Latin words; and indeed these errors are much more common in medical and biological than in chemical and physical writings. It is difficult to account for the fact that an Englishman will write '*vide supra*' when he means 'see above'. It is noticeable that those who use Latin tags most freely do not always know enough of that language to realize that the word 'data' is plural.

Long words derived from Greek or Latin roots are often used for expressing very simple ideas. When a man wants to say that something is visible to the naked eye on merely opening the body-cavity, he tries to make it sound grand by saying, 'this phenomenon can be macroscopically observed upon laparotomy'. Sometimes he uses short words, but chooses an elaborate way of expressing himself. Thus, if he wants to refer to a sheet of metal about 1/100 in. thick, he says that it is 'of thickness $\sim 10^{-2}$ in.'. If his intention is to tell his readers that the longest of the six pairs of chromosomes in a cell is about three times as long as the shortest, he writes, 'the maximum size range of the six pairs as represented by the ratio length of chromosome 1/length of chromosome 6 is about 3/1'.

The grandiloquent writer brings in abstract words where none is required. Instead of writing 'because the surface of the retina is spherical', he substitutes 'because of the sphericity of the retinal surface'. Instead of saying that something is near the nucleus, he says that it 'occupies a juxta-nuclear position'.

Genteelism is allied to grandiloquence. People who think it polite to call a napkin a 'serviette' have their counterparts in science, who cannot soil their mouths with paste or mash but must say 'Brei' instead. Another example is 'sacrificed' for killed. Allied to genteelism is the deliberate use—not just occasionally, but over and over again—of archaic words instead of their exact equivalents in plain modern English (for example, 'save' for except).

Vogue-words have their place in the vocabulary of the grandiloquent; but what may be called negative vogue-words must also be mentioned here—perfectly good words that for an inexplicable reason must not be used. Why must the word 'about' never be used by the grandiloquent? Why must they always say '*circa*', '*ca.*', '*c.*', 'approximately', 'around', 'of the order of', and even '$\sim$'? What is the objection to 'separate'? Why must 'discrete' invariably be substituted? (A case can be made for the occasional use of 'discrete', when special emphasis on complete separation is necessary.) 'After' is another negative vogue-word.

Grandiloquence and related foibles, however, are not the worst enemies of good English. A still more serious and more insidious evil exists.

In ordinary speech or writing it would never enter anyone's head to say 'a tea containing cup'; one would naturally say 'a cup containing tea'. Yet in scientific journals one will find (for example) 'iron containing globules', when what is meant is 'globules containing iron'. It is questionable whether the writers of such phrases have ever asked themselves why they adopt this construction, which is strange to our language and does nothing to improve it. Why do they say 'a hyaluronidase treated area' when they mean an area treated with hyaluronidase? Why place a complex adjectival phrase before the noun, and why omit the clarifying preposition? Why say 'non-formalin containing fixatives' instead of fixatives not containing formalin? Why 'eight micra thick sections' when one means sections $8\mu$ thick? Or why does a man who would never dream of saying 'the Jones associated people' write of 'the nucleolus associated chromatin'?

These, however, are relatively innocuous examples, compared with many that disfigure our scientific journals. 'A methylene blue stained preparation of rabbit ear skin' is bad enough, but not quite so bad as '*Dytiscus* red flight muscle sections' or 'the use of acidified (by $HNO_3$) or alkalized (by ammonia) solutions of silver'. Even these, however, are not the worst English that it is possible to write, if one is determined to pile up qualifying words other than adjectives in front of the noun they qualify. The limit is perhaps reached by 'adenosine triphosphate activated actomyosin contraction'. (To spare the reader trouble, I may mention that this means the contraction of actomyosin, activated by adenosine triphosphate.) These are words put together without the slightest attempt at clarity or any consideration for the reader. The phrase is worse than merely illiterate: it is rude.

This piling-up before a noun of words that are not adjectives, but are used adjectivally, is rather a new fashion in English scientific writing. It was seldom seen in Britain a quarter of a century ago. There can be scarcely any doubt about its origin. That many American scientists are of German descent is obvious when one looks at lists of authors in journals published in the United States. The process of piling up adjectival phrases is familiar to everyone who knows the German language. It does not make for clarity. It comes naturally to a German to write 'die einzigen, durch unmittelbare Beobachtung sicher zu ermittelnden Stellen' or 'das von dem Objectivsystem in der der Lichtquelle zugeordneten Ebene entworfene Beugungsspectrum'. Unnecessarily difficult though this construction may seem to an Englishman, yet the German language does at least help us, through the inflection of the words, to follow our path through such passages as these. But when this kind of construction is forced artificially on our much less inflected tongue, and the prepositions are omitted, all pretence of clarity is lost.

The German–American style did not originate with men who had set themselves the high ideal of improving our language as a vehicle for scientific ideas. It was, on the contrary, the product of childhood, introduced by people whose parents had spoken in sentences constructed in their native, German way. It is strange indeed that an Englishman or Scot, accustomed since infancy to a simple syntax, with logical order of words, should copy a German–American imitation of English, just because he happens to be writing in a scientific journal. Our own language, as written by those who know and love it, can scarcely be surpassed for clarity, directness and simplicity.

It is noticeable that scientific books published in the United States are often written in a style that is close to ordinary English (though the American people have their own special words, spellings and phrases). The difference in style between American books on one hand and papers on the other suggests that the publishers correct the style of writing where necessary, while the editors of journals do not. It must be remarked that the German influence is altogether lacking from some American scientific papers, which are models of lucidity and good style. A paper by Michaelis[1] on the reaction of dyes with nucleic acids may be quoted as a particularly fine example.

How can the standard of English in scientif journals be improved? One thinks at once of tl obvious works of reference—of Fowler[2], Partridg and Gowers[4]. Quiller-Couch's lecture "On Jargon" is packed with good advice and horrid example The teachers of English in our schools could hel very much, if they were to study the errors made i scientific papers and base their instruction to scienc students on their findings. Style, however, is largel dependent on example. Good reading makes goo writing. One could almost imagine that some of th contributors to our scientific journals had never rea anything but German–American. Yet good example abound, in books of widely different scope. A trio s diverse as Macaulay, P. G. Wodehouse and Si Winston Churchill have this in common, that thei English is lucid. There is no dearth of good example to suit every taste.

A strange fact that gives some basis for optimism is this. When an author has finished the scientifi part of his paper, he often addresses a note of genera information to the reader. At this point he suddenl discloses for the first time that he can write English for his ideas are clearly expressed. If one wished to translate what he now says into the style adopted in the rest of the paper, one would have to write something like this: 'Some related interest possessing observations by the present writer *et al.* will be the subject of *ca.* $10^{[illegible]10}$ discrete communications'. The fact that he does not write like that shows that he need not have done so in the body of the paper.

One last, necessary word. The best English writers occasionally use some of the strange constructions mentioned in this article, often to produce a special effect for a particular occasion. They do so, however, only at long intervals. The greater part of their writing is so smooth and fluent that the reader forgets that he is reading and knows only that he is absorbing ideas.

*Note.* With the exception of the passage in inverted commas in the last paragraph but one, all the examples given in this article are genuine: none was invented by myself or modified to suit my purpose. I am indebted to Prof. A. C. Hardy for a careful criticism of the first draft of this article.

# IMMUNITY AND DEVELOPMENT

"IMMUNITY and Development" was the subject of a session organized by Section D (Zoology) of the British Association at the Bristol meeting. The section opened with an address from the president of Section D, Prof. F. W. R. Brambell; an account of this address has already appeared in *Nature*[1]. In the four papers which followed, two principal themes were developed. The application of immunological techniques in embryology has led to new findings concerning the differentiation of various organs and tissues; these findings, and the way in which they can be fitted into classical embryology, were discussed. The development within the embryo of the immune response itself was also discussed.

Embryological investigations by means of serological techniques were reviewed in a paper by Mrs. R. M. Clayton, entitled "Differentiation and the Development of Tissue Specificity". Preparations of embryonic or adult organs may be inoculated into a suitable mammal or bird, where their protein or polysaccharide components act as antigens, eliciting the production of antibodies. An antibody produced in this way may then be used as a highly specific reagent in tests to distinguish or locate the corre-onding antigen. Tests have been devised in which e untreated antibody is employed *in vivo* or *in itro*; or the antibody may be labelled with a radioctive tracer or fluorescent dye so that its location an be observed. The results of such tests indicate hat adult organisms are composed of a complex osaic of antigens, with different but overlapping atterns of antigens characterizing each organ.

Immunological analysis has been applied to the deelopment of a variety of species, namely, the mouse, hick, newt, frog, sea urchin and certain insects. ome antigens are found throughout the life of an dividual, whereas others arise at definite times and laces during development. Transitory antigens are ound during development, and new antigens tend to ppear at crucial stages of development, such as astrulation or neurulation. During organogenesis nd embryonic induction, characteristic changes take lace in the distribution of antigens. The use of abelled antibody permits refined study of the localzation of antigens: localization has been observed ven at the cellular level. Antibodies have been used o produce alteration from the normal course of evelopment. It has been claimed, but not conlusively demonstrated, that naturally occurring ntibodies play a part in differentiation.

In his paper entitled “Zoological Implications of ctively Acquired Tolerance”, Prof. P. B. Medawar iscussed the new developmental phase of the antiody-producing system, and the corresponding novel ype of immune response, which he and his co-workers re investigating. The phenomenon of actively cquired tolerance can be expressed in the following erms: that mammals and birds never develop, r develop only to a limited degree, the power to eact immunologically against foreign homologous issue cells to which they have been exposed ufficiently early in foetal life. Acquired tolerance may be contrasted with the normal intolerance of mammals and birds to foreign homologous tissue: grafts of tissue from another member of the same species are normally rejected, as a consequence of an immunological reaction on the part of the host against the antigens of the graft. An example of acquired tolerance is the long survival and probable permanence of feather-bearing skin grafts between fowls of differing breeds, the hosts having been rendered tolerant by inoculation of donor tissue cells into the egg.

The fact that an animal is unable to produce antibody against its own tissues may be an example of acquired tolerance. The potentially antibody-producing tissue of an individual, at a stage of development when it is unable to manufacture antibody, is exposed to the antigens of the other tissues. Active tolerance of these antigens may consequently be acquired. Later, when the capacity to manufacture other antibodies develops, the individual is unable to do so against its own antigens. Exceptional antigens, as found for example in the central nervous system, are in fact capable of eliciting an immunity in the individual in which they are themselves found. This can be accounted for by the occurrence of such antigens only in sites normally isolated from the antibody-producing tissue, and therefore unable to provoke tolerance. Other naturally occurring examples of acquired tolerance can be found. A disadvantageous case occurs in man when the cells of a malignant melanoma pass from a mother across the placenta into the foetus, where they multiply and cause death. The survival of the cells in the offspring can be ascribed to tolerance, since cells of maternal origin do not normally survive in the offspring. Another example of tolerance acquired between individuals is provided by the passage of the *Rh* antigen from females into their rhesus-negative offspring. These females may be rendered tolerant of the rhesus antigen as a consequence. If they afterwards bear a rhesus-positive foetus, agglutinating antibody is manufactured less readily against the rhesus antigen of the embryo.

A remarkable deduction can be made from experiments in which normal lymph node cells are injected into a mouse bearing a foreign skin graft to which it is tolerant. The cells enter and presumably colonize the lymph nodes of their host; in due course the grafted skin is destroyed. Antigens must therefore be passing at all times from tissues such as the skin into the lymph nodes, whether or not the tissue is treated by its host as foreign.

A subject closely connected with the immunological relationship between mother and foetus was discussed in the paper of Prof. E. C. Amoroso, “The Endocrine Environment of the Foetus”. Hormonal relationships are found between the maternal organs concerned with pregnancy, between these organs and the foetus, and between the organs of the foetus. Uterine changes during pregnancy do not depend solely on stimuli emanating from the foetus, since many of the normal features of pregnancy can be elicited in the absence of a foetus. As the ovum moves down the oviduct it comes at first under the influence of the ovarian hormones, which control the state of the oviduct walls. Implantation is also under the control of ovarian hormones, and, via the ovaries, of the pituitary. Delayed implantation, a phenomenon of widespread and varied occurrence among mammals, is controlled jointly by the uterus, ovaries, and pituitary. After implantation, the maintenance of pregnancy is dependent on the ovarian hormones; however, some animals (including man) are able to produce the ovarian hormones in organs other than the ovaries, probably in the placenta. It is thought that in certain species the placenta is also able to secrete hormones functionally equivalent to œstrogen and progesterone. The action of the ovarian hormones in maintaining normal pregnancy appears to be on the uterine walls, and not on the foetus itself; for extra-uterine pregnancy may be maintained in the rabbit after ovariectomy.

Recent progress in the techniques of surgical manipulation of the foetus has advanced the analysis of endocrine relationships within the foetus. Decapitation technique has proved particularly helpful in the hands of the French school. The adrenal and thyroid glands of the foetus appear to be under the control of the foetal pituitary, as is also the growth-rate. The extent of pituitary control varies between different species. The differentiation of the genital system is under the control of hormones released by the gonadal primordia; the gonads and cranial duct differentiate from discrete primordia in either sex, whereas the urogenital sinus, the accessory ducts and glands, and the intromittent organ develop from neutral primordia. The appearance of ‘freemartins’ in heterosexual cattle twins is due to the passage of hormones in the blood stream when the circulations of the two individuals are crossed. The conventional explanation is that hormones from the male reach the female, arrest the differentiation of female structures, and stimulate the male components. An alternative explanation is that the female gonad may itself be affected, and that the masculinization is due to the hormonal influence of the freemartin gonad. The results of surgical removal of the foetal gonads indicate that the later differentiation of the male reproductive structures is under the control of androgenic secretions from the testis, although the role of oestrogenic secretions from the ovary is less clear. The production of gonadotrophins by the placenta is also thought to influence the development of the foetal gonads. Striking enlargements of the gonads of the foetus or new-born have been found in man and in such diverse species as the grey seal, horse, giraffe and elephant.

The subject returned to the detection of antigens during differentiation with a paper entitled "Hereditary Differences between Cells detected by Immunological Means", given by Dr. N. A. Mitchison. Knowledge of cellular heredity and differentiation is more advanced for micro-organisms than for the tissue cells of higher animals. Advances in the genetics of micro-organisms have followed the discovery of unit cell markers, the hereditary properties of which can be investigated; the conclusion may be drawn that unit cell markers are needed for the embryological study of differentiation. Antigens are eligible candidates as such markers. However, the results so far obtained with inter-specific immunization against organs are disappointing. Cross-reactions with the antigens of other organs are invariably found.

In marked contrast with this lack of specificity the results of auto-immunization, where an animal immunized against tissue from its own body. Prec immunities against central nervous system, periphe nerve, uveal tract and testis have been obtain experimentally by the use of Freund's adjuva Unfortunately for their usefulness in embryolog these auto-immunizations appear to belong to t category of immunological reactions mediated cells, and are therefore inaccessible by the standa techniques of serology. However, other types immunological response appear to belong to the sa category, such as transplantation immunity and t delayed reaction in hypersensitivity. Special tec niques developed for their investigation may also applicable to auto-immunization; for example, t transfer of immunologically activated cells in adoptive hosts, or the skin reaction to antigen immunized animals.

Several points of interest were raised in discussio The possibility that acquired tolerance might be use in hybridization was referred to, as was t possibility that a graft in a tolerant host might pic up antigens from the host. The need was mentione for a repetition of the experiments of Guyer an Smith, which were claimed to show that heredi ary changes could be produced by immunologic means.

# PEACEFUL USES OF ATOMIC ENERGY

## RADIOISOTOPES IN CHEMISTRY, TECHNOLOGY AND INDUSTRY

By Dr. HENRY SELIGMAN
Atomic Energy Research Establishment

NOBODY expected great revelations at the Geneva Conference on "The Peaceful Uses of Atomic Energy" on work concerning radioisotopes. Isotope applications, in contrast to some other subjects discussed at Geneva, were always free from any security restrictions, and therefore exchange of knowledge and techniques as well as results was possible in the past. The conferences which dealt exclusively with isotopes technique at Oxford (1951 and 1954) were good examples of such collaboration in this field between many countries. An article referring to biochemical, biological and agricultural uses has appeared already in *Nature* (October 22, p. 765). One part of the plenary session and five full sessions were devoted to isotope uses in chemistry, technology and industry.

The first paper of the plenary session, which dealt with survey papers in the field of technical isotope uses, was by P. C. Aebersold (United States), who discussed the importance of isotopes in technology and industry. His paper gave a very complete survey of all practical industrial uses of isotopes in the United States. The specific uses he mentioned were beta-emitters on phosphor materials for luminescence, and the applications of isotopes for voltage production. He discussed several possibilities of making radioisotope-batteries, like the exposure of a semi-conductor to radiation. He also discussed the use of radiation of fission products, and was hopeful that the sterilization of certain drugs would be not only possible but also economical. The following lecture, by H. Seligman (United Kingdom), describe advances during the past two years made in th United Kingdom in industrial isotope techniques He mentioned the development of an instrument fo detecting corrosion of pipes from the outside, a new type of instrument for well logging to find the oil-brine interface, and the possibility of sorting coa from shale. J. Guéron (France) gave examples o recent French development in that field. He discussed the work of finding leaks in underground cables and the measurement of hydrogen content in soils by neutron scattering. The tracing of sand in the Mediterranean was described, and details given on the identification of carbon deposits in boreholes using radioactive methods.

The specialized isotope sessions dealt with the following subjects: (1) general uses, production and handling; (2) reaction mechanisms; (3) activation analysis; (4) research in metallurgy; (5) control and technology; (6) fission product applications.

### General Uses, Production and Handling

C. E. Eddy (Australia) and C. Simane (Czechoslovakia) gave a survey describing the uses of isotopes in their countries. S. E. Eaton (United States) gave some examples of isotope uses in industry, such as investigating the mechanism of silver plating, and the study of de-icing of aircraft tyres by using tagged silicones.

The production of isotopes received relatively little space at this Conference. A. F. Rupp (United States) ave a survey of large-scale isotope production at ak Ridge, and P. E. Carter and L. O. Myerscough United Kingdom) gave a paper on the production of eta-ray sources for industrial and clinical uses. K. amsahl and K. Taugbol (Norway) reported on their ecent successful preparation of carrier-free phoshorus by a simple diffusion method. Two other apers dealt with the handling of isotopes.

## Reaction Mechanisms

A paper by V. N. Koudratyev (U.S.S.R.) gave examples of work done in the Soviet Union to show the high efficiency of tracer techniques in studying the mechanism of chemical reactions. Kondratyev pointed out that the greatest progress can only be made in this field if the tracer methods are employed together with other more orthodox methods of investigation. He mentioned the investigation of the mechanism of the formation of aldehydes, the isotopic exchange of sulphur between elementary sulphur and organic polysulphides and many others. J. Turkevitch (United States) reported on the use of stable and active isotopes in the study of heterogeneous catalytic reactions. He discussed, for example, his work on the migration of the double bond in an organic system using tritium. Carbon-14 has been used for investigating the Fischer–Tropsch reactions between carbon monoxide and hydrogen with an iron catalyst. A great number of investigations were also mentioned using deuterium as the label. W. G. Brown *et al.* (United States) summarized work on the use of tritium in chemical research. They discussed the isotope effect on reaction-rates and the mechanism of nitrobenzylhalide reactions.

## Activation Analysis

Only a few papers were given covering this field. One by V. V. Jakovlev (U.S.S.R.) dealt with the determination of rare earths by neutron activation in graphite, beryllium and germanium. I. P. Alimarin (U.S.S.R.) gave details of the application of radioisotopes in co-precipitation methods, the stability of complex compounds and many other analytical problems. A. A. Smales (United Kingdom) outlined recent advances in radioactivation analysis. One example was the determination of trace impurities without using any radiochemical separations, with a single-channel gamma-spectrometer. Other applications described the determination of elements with much greater accuracy than was possible with orthodox methods.

## Metallurgy

G. V. Kurdyumov (U.S.S.R.) dealt in his paper with the investigation of diffusion and atomic interaction in alloys with the aid of radioisotopes. This well-established method of following the behaviour of marked isotopes in alloys has been applied by Kurdyumov for ferrous as well as non-ferrous alloys.

## Radioisotopes in Control and Technology

J. L. Putman (United Kingdom) gave some details on the work proceeding in the United Kingdom in his paper on the development of thickness gauges and allied instruments. Technological advances in instrumentation based on the prompt emission of γ-rays after absorption of neutrons have been used in well-logging equipment, and single-channel gamma-response has made the development of corrosion detectors a possibility. C. Crompton (United States) spoke on applications of radiation involving penetration and reflexion. Interesting applications are those of X-rays from *K*-capture to detect and measure sulphur. Crompton also gave details of the utilization of bremsstrahlung from strontium-90 to measure silt densities in lakes. Another application of bremsstrahlung was described by P. Leveque *et al.* (France). He gave details of such a source used for radiography when very low γ-ray energies are necessary. J. L. Putman and S. Jefferson (United Kingdom) discussed the application of radioisotopes to leakage and hydraulic problems; in both these fields much progress has been made in the United Kingdom. A. M. Samarin (U.S.S.R.) described the study of production processes of steel and iron by the use of radioisotopes. The elimination of phosphorus and sulphur during the production process has been followed and equilibrium studies completed. Solidification phases have also been measured after radioactive indicators have been added to an ingot. A paper by D. B. Grozin (U.S.S.R.) dealt with the by now orthodox methods of metal–wear investigations of oils for motor-car engines. The general feeling was that the metallurgical applications, while not new, are extremely useful; and they are in widespread use in Russian industry.

M. Kato (Japan) gave details of work done in his country dealing mainly with isotopes applied to process and quality control. A paper by U. Been and E. Saeland (Norway) dealt, among other things, with some interesting industrial uses of isotopes in Norway. They showed how isotopes have helped in understanding different factors in the production of cement, and they have determined the amounts of catalyst used during the production process.

## Fission Products and their Application

One session was devoted to the application of radiations from fission products, a subject which will be of great importance in the near future. It is no accident that on this topic five of the seven papers came from the United States. That country has until now done most of the research in this field. The next few years should bring much more information on the use of these 'strong' sources, as all countries are making great research efforts in this field. L. C. Anderson *et al.* (United States) dealt with the use of gamma-radiation for chlorination of aromatic compounds. They have proved that for certain chlorinations the use of a powerful gamma-source may well be economical. They gave some details on polymerization products of ethylene. The radiation effects on long-chain polymers were dealt with in a paper by A. Charlesby (United Kingdom), who gave a survey of the developments in that field to date. B. E. Proctor and S. A. Goldblith (United States) gave a well-balanced summary on sterilization of foods. The authors predict "the initiation of commercial processes for irradiation sterilization of some pharmaceuticals, food, tissues and packaging materials in the present decade". L. E. Brownell and J. J. Blumer (United States) think the sterilization of medical supplies by gamma-irradiation promising. H. J. Lomberg and S. E. Gould (United States) found that by irradiation the trichinosis cycle in pork can be interrupted, and they believe that this treatment will also be economical. A paper by E. G. Linder *et al.* (United States) dealt with the conversion of radiation into electrical energy. They conclude that practical power sources can only be achieved economically if low-energy beta emitters of long half-life can be made available at low cost and in large quantities. When, however, only microwatt applications are needed, the present sources suffice.

Isotopery was exhibited at both the Palais des Nations and the Palais des Expositions. Most isotope exhibits were in the Palais des Nations. The Russians showed quite a number of their industrial applications and equipment made for process control. The United States' effort, although generally more on the reactor side, gave still a complete picture of isotope applications. The French exhibited a few, but original applications. The United Kingdom isotope applications were shown in the Palais des Expositions placed centrally between exhibits of British industry. These applications illustrated very well the progress of the past three or four years.

The Geneva Congress gave a very good cross-section of all isotope work although, owing to the very full agenda, there was far too little time to discuss single problems in detail. The spirit in general was above all expectations. The sponsors must be congratulated on the choice of papers, and the very smooth organization which they achieved in spite of the short time given to them for the arrangement of the Conference. I feel that, in order to get the maximum benefits out of such interesting meetings, it may be better in future to have the isotope conferences separate from those on atomic energy.

# THE PAMETRADA RESEARCH STATION

## OPEN DAYS FOR ENGINEERS

FIVE years ago the Pametrada Research Station, Wallsend on Tyne, held a series of open days for a whole week to publicize the first five years of its existence (see *Nature*, 165, 963; 1950). During the first week of last October, the Station was again opened, to show its further progress. This time there were fifty-three separate exhibits in the laboratories, more than half of which had been developed in the period under review, some showing most ingenious applications of science to the solution of engineering problems in this field. The research association came into existence "to carry out research, to improve and develop complete steam and gas turbine installations and to advise member firms on all matters associated with the design and layout of marine turbines and gearing, and to set up standards of fit and finish required in the principal components of turbine machinery". Its name is derived from the initial letters of its full title: The Parsons and Marine Engineering Turbine Research and Development Association. To see the Research Station in action as the visitors did, ten years after its foundation, was to appreciate the courage and faith of its founders in the value of applying science in their industry. The aim of the director, Dr. T. W. F. Brown, then was, and still is, not merely to keep marine engineering in Great Britain abreast of competition, but also to keep it ahead of the rest of the world.

The value of the site, buildings and equipment now exceeds a million pounds, while there is a staff of more than three hundred. Some of the equipment for full-scale trials of marine turbines is the largest of its kind in the world. No such test equipment existed in the early days of the steam turbine, and this may have been one of the causes of its very slow development in the years immediately following the death of Sir Charles Parsons in 1931. To apply scientific methods to the improvement of marine propulsion machinery to-day, it is of immense value to have test equipment large enough to make full-scale trials ashore.

Most of the work at the Station has been done on the steam turbine; but during the past five years considerable effort has been devoted to improving the gas turbine for marine work, and the experimental 3,500-s.h.p. marine gas turbine that was on view five years ago has since been run over a wide range of operating conditions and with different fuels. These have shown that, when residual oil is used (which is necessary in marine work for economic reasons) serious troubles are encountered with fouling and corrosion, unless expensive additives are used.

The most impressive exhibit was the experimental gas-turbine rig, in which the combustion chamber and stator were operating at a gas temperature of 2,200° F. and a mass flow of 5¼ lb. per second. The stator was lined with blades of ceramic material, and the demonstration was shown without the turbine rotor so that the distortion of the stator and combustion chamber could be studied with the combustion chamber alight. This rig will later be fitted with a turbine rotor having liquid-cooled blading, each hollow blade containing a mixture of liquid sodium and potassium metal, to transfer heat down the blade axis to the root embedded in the rotor shaft, which is water-cooled. A special technique is required to handle the liquid alloy of sodium–potassium, which is used as the heat transfer medium, because it is so chemically active in the presence of air and moisture. Means for doing this were shown in another exhibit, the so-called 'dry box'—a glass-sided chamber, in which helium is continuously circulated over the specimens. The design is based on that of a similar chamber used at the Atomic Energy Research Establishment, Harwell, for handling radioactive materials. Impurities in the helium atmosphere of the dry box of 1 part in 100,000 can be detected.

Apparatus was on view designed for studying liquid cooling for gas-turbine rotor blades. A single hollow blade with a suitable liquid enclosed in the cavity was carried at the end of a rotating arm, driven by a steam turbine at speeds up to 11,000 r.p.m., heat being supplied electrically to the extremity of the blade and taken away by water flowing over its root. Exhibits on a smaller scale showed studies of refractory materials such as silicon carbide that are suitable for use as nozzles in uncooled furnace linings in high-temperature gas turbines. One of the several tests to which these parts were subjected was repeated thermal shock, the temperature being changed in a matter of seconds from 1,000° F. to 2,200° F., and vice versa, for hundreds of hours.

Research on the steam turbine is at present mainly concerned with the development of a double-casing high-pressure turbine in which the inner barrel exhausts into the annular outer casing, which is therefore subject to exhaust steam pressure and temperature and so is relatively cool (400° F.), when compared with the inlet temperature (900–1,200° F.). A 14,000-h.p. high-pressure turbine of this type was shown under test. This design is a logical development from a number of successful double-casing low-pressure turbines already in service at sea. Tests have been carried out on a quarter-scale model of this turbine casing to determine the transient distortions of the casing such as may occur during manœuvring and under steady-running conditions. Another exhibit in this section was an instrument that has been developed to enable turbine rotors to be rebalanced in their own bearings on board ship at low speeds. The bearing pedestal vibrations were detected by a relative electromagnetic pick-up activated by a tunable mass–spring system that could be tuned to resonance at the turbine rotor speed, so that vibrations at this frequency were highly magnified. By suitable attachments the vibrational velocity, which is proportional to the out-of-balance resultant force, and the position of this force around the shaft from a reference point were indicated, to provide the information required for rebalancing.

The staff at Pametrada have become famous for their application of electronic techniques to the study of noise and vibration on ships at sea, very largely due to the inspiration and leadership of the late Mr. H. G. Yates, senior designer. Specialist instruments have been designed for this work, including a portable vibration-meter, Muirhead–Pametrada wave analyser, low-frequency wave analyser, automatic wave analyser and electronic torsiograph. The use that has been made of such equipment on board ship has now made it possible for the vibration characteristics of even the most complicated gear and turbine machinery to be predicted in the design stage with a considerable degree of accuracy.

Much attention has been paid to the improvement of transmission machinery, both by the study of toothed gearing of all kinds and by the design and testing of hydraulic reversing transmissions, of which a working model was on view. Six scale models in 'Perspex' showed the space requirements, machinery weights and fuel consumptions for comparable machinery installations of various types designed for a power of 10,000 s.h.p. Present-day requirements of steam turbine, gas turbine and diesel engine were shown by the first three, which could be compared with the others—a high-temperature high-pressure steam turbine set, a high-temperature gas turbine with water-cooled blading, and a steam turbine set supplied with steam from a nuclear reactor.

It was shown that during the past decade the cost and weight of marine turbine and transmission machinery has been reduced by 15 per cent and 50 per cent respectively, while efficiency has been improved 12 per cent. An impressive array of pictures of ships engined by Pametrada designs was on view, the total shaft horse-power of those completed and already in service exceeding 2¼ million. A recent change of policy has led to installations of Pametrada design being built by two licensees in Holland and one in Canada. The hope of those responsible for the exhibition is that owners of ships having seen it may go away and order the most up-to-date machinery embodying the results of this research, instead of being content with conventional designs.

# CHEMICAL RESEARCH LABORATORY, TEDDINGTON

## OPEN DAYS

THIS year the Chemical Research Laboratory, Teddington, of the Department of Scientific and Industrial Research, held its open days during September 27–30, and again the invitations attracted a large number of visitors from government departments, industry, universities and schools. Some of the outstanding exhibits by the six research groups are briefly described in this article.

A feature in the Corrosion of Metals Group was the illustration of advisory services to industry, public bodies and other inquirers. These services, which constitute an important part of the work of the Group, were depicted in two ways: one gave typical inquiries and replies in summary form, the other showed selected letters and the replies almost in full. The questions and answers dealt with a wide variety of subjects and from diverse sources, such as an interested layman, a county surveyor and a research association. The information supplied is based on general corrosion science and on the knowledge gained either in *ad hoc* investigation or in fundamental researches within the programme of research of the Group.

The results of radioactive tracer studies of corrosion inhibition were illustrated graphically. Potassium chromate containing a proportion of radioactive chromium atoms is used, and the amount of chromium found on a steel surface after immersion in the radioactive solution is estimated from the amount of radiation emitted from the surface. Using this technique, it has been shown that during immersion in chromate the growth of the protective film containing chromic oxide on the surface of the metal obeys the same law as the formation of a surface film of ferric oxide during exposure of steel to air. One exhibit illustrated the work being carried out on the development of tarnish-preventive wrappings for use with copper, silver and their alloys. The access to the metal of hydrogen sulphide (small traces of which in the atmosphere are responsible for tarnishing) is prevented by incorporating in the wrap a substance that absorbs the sulphide or converts it to an innocuous compound, or acts as a barrier. A number of additives have been found effective. They include chlorophyll, certain salts of chromic, nitrous and phosphoric acids, hydroxides of certain metals, and tannins with and without the addition of alkali. The investigation is still at an experimental stage, but the results of laboratory tests have been confirmed by exposure in an outdoor shed, and in a sideboard and over a mantelpiece of a living room. Patent applications have been filed both in Great Britain and abroad, the exploitation of these patents being in the hands of the National Research Development Corporation.

The exhibits on view in the Inorganic Group covered the three main lines being pursued by the Group, namely, the preparation of pure elements, the separation of the rare earths and the search for useful elements in wastes and low-grade materials. The demand for highly pure elements for semiconductor research has led to a study of methods of purification, and equipment for the zone-refining of bismuth, gallium and tellurium was demonstrated. For the separation of the rare earths, ion-exchange methods are being examined, coupled with the use of the 'complexone' type of reagent. A large plant has been constructed that will handle kilogram quantities of mixed earths. It consists of two banks of eight columns, all interconnected, together with ancillary equipment, and each column has a resin bed about six feet in depth. A laboratory model of the plant was also on view, as well as a small collection of rare-earth minerals. This research also includes the preparation of the pure rare-earth metals; but this has so far been confined to cerium and lanthanum, small ingots of which were shown. The third line of research was illustrated by the search for selenium in waste products and its discovery in sludges collecting in certain parts of the plant for purifying sulphur dioxide produced by the burning of pyrites in flash roasters. Specimens of the various dusts and sludges occurring in the various stages of the purification plant were on view, the selenium content of these varying from a few parts per million to 60 per cent. This source could provide a substantial additional contribution to the limited supplies in Britain. The excellent collection of pure metals stocked by the Pure Metals Committee of the Department of Scientific and Industrial Research was also on view.

A new type of paper chromatography, which makes use of chemically modified cellulose, was exhibited by the Radiochemical Group. By phosphorylation or amination, normal cellulose is converted to cation- or anion-exchange material respectively and from these special forms of cellulose sheets of paper and columns of powder are prepared for the separation of various metal and acid mixtures. Aqueous solutions of simple salts are used as solvents. Field techniques for the determination of trace metals in soils for geochemical prospecting purposes were again on view. The range of metals dealt with has been considerably extended by the use of both chromatographic and colorimetric procedures.

A new ion-exchange process for the recovery of gold from cyanide solution, which takes advantage of the high selectivity for aurocyanide shown by a weak-base dimethylamine-type resin was demonstrated. This resin enables gold to be extracted from a cyanide solution containing other heavy-metal cyanides with almost 100 per cent selectivity. Another ion-exchange exhibit indicated how uranium can be recovered from dilute sulphuric acid solution by adsorption on a strong-base ion-exchange resin. A new development in the use of solvent extraction for the recovery of metals was illustrated by the use of a kerosene solution of acetyl pyrophosphate for the extraction of uranium from an aqueous solution of phosphoric acid. A physical investigation being undertaken uses a quartz spectrograph with a photomultiplier as light detector to study positive-ion plasma oscillations in halogen-quenched Geiger counters.

Among the exhibits shown by the Organic Group was a semi-micro zone-melting apparatus in which 0·15 gm. of compound can be purified. The material under treatment is contained in a glass tube of 2 mm. internal diameter which is moved vertically upwards at a speed of 1 in./hr. A short molten zone is produced by focusing the filtered light from a 100-W. lamp upon the specimen. The removal of 0·05 per cen of induline from naphthalene was demonstrated. A further exhibit was concerned with a new class of compound containing the pentocyanoferrate group (see *Nature*, 176, 80; 1955). Experiments were shown supporting the structure $[Fe(CN)_5H\dot{N}C_6H_4OH]^{3-}$ for the ion, obtained by the reaction of $Na_3[Fe(CN)_5NH_3]$ with *p*-aminophenol. Possible applications of the intensely coloured compounds of this series included in the exhibit were as spot reagents for metals and for aromatic amines in paper chromatography, and their use in organic syntheses.

Methods for the determination of the molecular weights and molecular-weight distribution of high polymers are being investigated by the High Polymers Group. Instruments shown included an ultracentrifuge, a micro-diffusion apparatus and a light-scattering photometer. Of particular interest was the ultra-centrifuge, which can be used both for analytical and preparative purposes and in which the sedimentation of polymers in solution can be studied both visually and photographically. Zimm–Myerson type osmometers are being used for demonstrating the behaviour of synthetic membranes of graded permeability which have been prepared during research on the osmotic properties of membranes.

Other exhibits by the High Polymers Group illustrated the preparation and uses of ion-exchange membranes. These exhibits included a model electrodialytic cell of the type which can be used for the desalting of brackish water; the water to be treated is passed continuously through the cell, which contains a series of compartments separated by cation- and anion-exchange membranes arranged alternately. In fundamental studies on ion-exchange equilibria, factors determining the selectivity of ion-exchange resins have been investigated. A simple method for the preparation of paper with ion-exchange properties has recently been devised in which the paper is prepared by incorporating a finely divided ion-exchange resin in a cellulose pulp, and experiments were shown illustrating the use of both cation- and anion-exchange papers of this type in chromatographic separations.

The National Collection of Industrial Bacteria, which this year has supplied more than a thousand cultures to industry and research establishments, demonstrated the various techniques employed: methods of preservation, pure culture isolation, freeze-drying in various suspending fluids, morphological and biochemical tests, methods of assay, etc. There were also striking displays of pigment-producing bacteria and antibiotic-producing organisms.

The Microbiology Group also exhibited a new and unusual cytochrome isolated from the strictly anaerobic sulphate-reducing organism, *Desulphovibrio desulphuricans*; it is notable as the first cytochrome to be observed in an obligate anaerobe, and it acts as the major link between the oxidation of organic carbon compounds and the reduction of sulphate by the cell. A continuous fermentation technique, almost automatic in operation, is being used for the reduction of sulphate to sulphide, with hydrogen gas as the reducing agent and carbon dioxide as the main carbon source for cell growth. The same process is being used in the mass production of sulphate reducers for the extraction of cytochrome. Another demonstration illustrated the production of hydrogen sulphide (and therefore sulphur or sulphuric acid) from raw sewage sludge enriched with sulphate. The hydrogen sulphide is produced at the expense of methane normally evolved during the anaerobic digestion of sludge ; but this drawback is being overcome by the development of methane-producing strains resistant to the inhibitory effect of sulphide. Bacteria concerned in the decay of pyretic fossils, a cause of some perturbation in museums, were also on view.

# OBITUARIES

## Prof. James B. Sumner

JAMES B. SUMNER, professor of biochemistry at Cornell University, Ithaca, New York, best known as the first to achieve the crystallization of an enzyme, died on August 12 at the age of sixty-seven at Roswell Park, Buffalo, New York. He had been in excellent health up to a few months before his death. He is survived by his wife, three sons, two daughters and seven grandchildren.

The crystallization of urease in 1926 was Prof. Sumner's most important scientific achievement. The history of this work can be read in his own words in "The Story of Urease" (*J. Chem. Education*, 14, 255 ; 1937) by anyone who wishes a first-hand, true-to-life account of his prolonged efforts to purify the enzyme and then to defend his idea of its chemical nature against severe and intolerant criticism. His skilful refutation of this criticism required experiments of a highly ingenious and exacting nature.

Prof. Sumner was also well known for his work on the enzyme catalase. Another of his major accomplishments that is, however, not so widely known was the first crystallization of a hæmagglutinin (concanavalin *A*) from jack-bean meal, and the discovery that this protein required the presence of a divalent metal for its action.

Prof. Sumner was an excellent teacher as well as research worker, as the writer can testify from personal experience. He constantly brought his lectures to life by means of a variety of personal anecdotes. He was probably at his best, however, in the less formal teaching of his assistants and graduate students, to whom he communicated his wide knowledge of practical laboratory technique.

In carrying out his own research, Prof. Sumner impressed one as being something of a magician. He would often work furiously without revealing exactly what he expected to discover, and then the rabbit would appear. It should be added, however, that in the case of urease, nine years of persistent work were required before his final objective of isolating the enzyme was attained. His thinking was concrete rather than abstract, and his mind operated by brilliant flashes of intuition rather than by the more laborious process of logical deduction from a given set of premises.

Prof. Sumner was somewhat abrupt in manner, and this was apt to lead people to an attitude of reserve towards him until they found by closer association that his true nature was one of kindness and humanity. He was a very loyal friend. He was free from the intolerable conceit often shown by persons of considerable attainment, although he was justifiably proud of his accomplishments. It is unfortunate that, despite being made a joint recipient of the Nobel Prize in 1946 and being elected to the U.S. National Academy of Sciences, he appeared to retain a certain amount of embitterment from the unjustified criticism to which he had at one time been subjected.

Prof. Sumner lost one arm above the elbow in a hunting accident when he was in preparatory school. This may have been an important factor that spurred him on to success in biochemistry, in the face of discouraging advice. In spite of this handicap, he also became an excellent tennis player, and was fond of outdoor sports such as skiing, sailing and hiking.

Prof. Sumner introduced a new era into biochemistry. He lived to see the fruition of his discoveries and on his deathbed he must have felt the satisfaction, in spite of his great suffering, of knowing that he and his work had already become a recognized and important chapter in the history of biochemistry.

ALEXANDER L. DOUNCE

## Mr. Harold Burrows, C.B.E.

HAROLD BURROWS, whose death occurred on September 29, will be greatly missed in the world of medical science. His career was both brilliant and unique. After leaving Marlborough College, he qualified in medicine at St. Bartholomew's Hospital, London, in 1899. He soon distinguished himself as a surgeon and, serving in that capacity in the First World War, was twice mentioned in dispatches. At the conclusion of hostilities he retained his link with the Services by accepting the appointment of consultant surgeon to H.M. Forces with the rank of colonel. In 1919 he was made C.B.E. On resuming his profession after the War he gradually built up one of the largest practices in the west of England, becoming consulting surgeon to both the Welsh Orthopædic and the Gosport War Memorial Hospitals. Harold Burrows received the Jacksonian Prize of the Royal College of Surgeons in 1922 and in the same year was appointed a Hunterian professor. The latter distinction was again conferred upon him in 1933 and 1935.

Shortly after publishing "Pitfalls in Surgery" in 1926, which was an important contribution based largely on his own experiences as a doctor, he became conscious of the strain his large practice had upon his health, and was finally persuaded to abandon clinical work. In 1927 he became a voluntary worker in the research department of the Royal Cancer Hospital, which later became known as the Chester Beatty Research Institute. Burrows was a keen and observant naturalist with a profound biological background, so the transition from medical practice to the life of a laboratory worker was not unduly difficult. In 1930 he was appointed experimental pathologist to the research staff of the Hospital.

Even while engaged in medical practice, Burrows had managed to keep abreast with scientific literature, and his special interest lay in endocrinology and the relationship of hormones to certain forms of cancer. Very naturally this became his special field ; but his interests in cancer research covered a very wide range. He published, apart from his several textbooks, more than seventy papers since he gave up practice in 1927. Some of these articles, mainly on experimental carcinogenesis, were published in collaboration with Sir Ernest Kennaway, Sir Charles Dodds and Profs. J. W. Cook, W. V. Mayneord and E. Boyland. Apart from these numerous scientific contributions, his book "Biological Action of the Sex Hormones", published in 1945, was in many ways a classic. With his combined clinical and biological knowledge, few were better qualified than Burrows to write a book on this complex subject.

It was a critical review of the subject and dealt mainly with the physiological activities of the sex hormones and the reactions of normal tissues to them. A second edition was published by the Cambridge University Press in 1949.

After his retirement from the Chester Beatty Research Institute in 1945, he collaborated with E. S. Horning and published "Œstrogens and Neoplasia" in 1952. This book dealt exclusively with the part played by the sex hormones in both the induction and prevention of certain forms of endocrine cancer, and included much of Burrows's own fundamental work. When Lacassagne in 1932 published his fundamental discovery that œstrogens were implicated in the cause of mammary cancer, Burrows was already working on the same problem and was therefore one of the first to confirm Lacassagne's results. Continuing his researches along these lines, he was the first to discover the relationship of œstrogens to the induction of scrotal hernia in rodents, and also to find that œstrogens are not only carcinogenic but al carcinostatic, since they are capable, under certa conditions, of restraining the growth of some form of hormonal neoplasms.

Burrows was particularly interested in the endo crine factors involved in the causation of tumours the reproductive organs, and shortly before he die at the age of eighty he had already completed th manuscript for a book on this important subjec His last contribution was published in 1954 in th *Journal of Obstetrics and Gynæcology.*

Harold Burrows's many researches over a wid field of cancer, especially those on the study of dis orders of the endocrine glands and their relation t the induction of neoplasia, form a very importan contribution to our present-day knowledge of thi subject. Many have lost a good colleague; but a can take consolation in the fact that his work ha helped to enrich the annals of science.

E. S. Horning

---

# NEWS and VIEWS

## The Negative Proton

The University of California and the U.S. Atomic Energy Commission have jointly announced the detection of the negative proton, or 'anti-proton' (cf. *The Times*, October 20). Protons which had been accelerated to an energy of 6,200 MeV. in the bevatron, the proton synchrotron of the University of California Radiation Laboratory at Berkeley, were allowed to collide with a copper target. Negatively-charged particles coming out in a forward direction from this collision were selected and separated in momentum by a focusing and analysing magnet system to provide a beam of negative particles of known momentum. After a time of flight of about one-tenth of a microsecond, this beam may be expected to consist mainly of negative pi- and mu-mesons, with some negative *K*-mesons (mass about 965 electron masses) and possibly negative protons. These particles were then distinguished both by measurement of their time of flight from the target (since particles of different mass have different velocities for given momentum) and by means of a device measuring the velocity of each particle passing through by the angle of its Čerenkov radiation. In this way the presence of negative particles with protonic mass (within about ten per cent) and distinct from the known *K*-particles and hyperons was established. Their rate of production for the momentum and direction of this experiment was about one negative proton for every 50,000 negative pi-mesons with the same momentum and direction.

No clear evidence of the existence of the negative proton had previously been available. A very direct interpretation could be given for several isolated cosmic-ray events which have been reported by invoking the negative proton, but these interpretations were not unambiguous. On the other hand, theoretical physicists have always had great difficulty in constructing any relativistic theory of the neutron and proton which did not require the existence of their 'anti-particles', the anti-neutron and the negative proton. The theories which have been proposed suggested that these anti-particles could be created together with a proton or a neutron, a nucleonic pair-creation process, when sufficient energy was available to form the rest mass of the nucleon-antinucleon pair in accord with the Einstein relationship between rest mass and energy. The negative proton would be stable in vacuum, but it was expected to react rapidly on collision with normal nuclear matter, a negative proton and a normal nucleon undergoing mutual annihilation and becoming transformed into lighter mesonic particles. It seems most probable that this annihilation process would generally lead to two or three fast pi-mesons, although there are also other possibilities. It has not been established experimentally yet which are the annihilation processes of importance.

The discovery of the antiproton has removed a major uncertainty in theories of the structure of the basic nuclear particles. It may thus be compared with the discovery in 1932 of the antiparticle to the electron, the positively-charged electron known as the positron, in accordance with the prediction of Dirac's theory of the electron. The importance of the present discovery lies in showing that symmetry between particle and anti-particle, already known to hold for the electron and positron and for the positive and negative pi-mesons, is characteristic also of the heavy nuclear particles, and may therefore be expected to be a general and deep feature of any account of the elementary particles of Nature.

## Industrial Fund for the Advancement of Scientific Education in Schools

Some companies which are concerned in the chemical, electrical and mechanical engineering fields of industry, viewing with growing disquiet the shortage of scientists, mathematicians and technologists, have decided to take steps to assist the teaching of pure and applied science and mathematics in secondary schools. The names of the companies are: Associated Electrical Industries, Ltd.; British Insulated Callenders Cables Co., Ltd.; British Petroleum Co., Ltd.; British Portland Cement Manufacturers, Ltd., Group; Courtaulds, Ltd.; The Distillers Co., Ltd.; English Electric Co., Ltd.; Esso Petroleum Co., Ltd.; General Electric Co., Ltd.; Arthur Guinness, Son and Co., Ltd.; Imperial Chemical Industries, Ltd.; Imperial Tobacco (Great

Britain and Ireland) Co., Ltd.; Rolls-Royce, Ltd.; The Shell Petroleum Co., Ltd.; Tube Investments, Ltd.; Vickers, Ltd.; The Wellcome Foundation, Ltd. These companies have accordingly established n Industrial Trust, to be known as the Industrial Fund for the Advancement of Scientific Education n Schools. For capital works at maintained schools, public funds are available, but no such help exists for independent schools and direct grant schools, at many of which the facilities are seriously inadequate hrough lack of capital resources, and it is therefore o these that the sponsoring companies are directing heir intentions. The assistance will be given solely y the provision of capital grants towards the uilding, expansion, modernizing and equipping of cience buildings in independent schools and direct grant schools in the United Kingdom, the Channel Islands and the Isle of Man. More than one and a alf million pounds has already been guaranteed; ut it is believed that many other companies that epend on adequate supplies of pure and applied scientists and technologists will wish to add their support. Indeed, only shortage of time has prevented their being approached already.

An Executive Committee of the Fund has been formed, consisting of the following: Sir Wilfrid Anson; Mr. R. A. Banks; Sir Hugh Beaver (*chairman*); Mr. E. H. O. Elkington; Dr. Willis Jackson; Mr. W. E. Jenkins; Prof. G. F. Mucklow; Mr. J. A. Oriel; Dr. F. Roffey; Dr. C. P. Snow; Sir Alexander Todd; Lieut.-Gen. Sir Ronald Weeks; Mr. A. H. Wilson. The secretary of the Committee is Mr. Peter Ashton, of Courtaulds, Ltd., and the address of the Fund is 20 Savile Row, London, W.1. It will be the responsibility of this Committee to adjudge and assess all applications; its decisions will take into account both the volume and quality of the existing science teaching in any school, as well as the nature of the proposals put forward to extend and improve t, and the steps which the school has taken to help itself.

## Future Policy of the Wellcome Trust

Sir Henry Dale, chairman of the Wellcome Trust, has recently explained the activities of the Trust in relation to the Wellcome Foundation from which its funds are derived, and also the character of its benefactions up to date. The Trust came into existence in 1936 on the death of Sir Henry Wellcome, though the activities of the Foundation and its associated branches commenced much earlier. The first demand on the Trust was the payment of very heavy estate duty, for which Sir Henry Wellcome had made no provision in his will, and for the first five years of its existence all the income of the Trust, which was derived from dividends received on its shares in the Wellcome Foundation, Ltd., was devoted to paying off this duty. Although the Foundation's profits during the Second World War rose considerably, due to the expansion of business in the manufacture of medical and therapeutic supplies, most of the money was either taken as excess profits tax or used in the new capital expenditure demanded by the urgent war-time expansion of its activities. Nevertheless, the Trust has been able to function to a limited extent, the most notable of its benefactions being the endowment of a Wellcome chair of tropical medicine and a Wellcome chair of pharmacology in the University of London. In addition, it has given funds for numerous fellowships and studentships both in Britain and overseas, and has also made provision for an important new medical library for the Royal Society of Medicine, and for three large museum floors, for anatomy and pathology, as a major part of the new building of the Royal College of Surgeons in Lincoln's Inn Fields. Sir Henry Dale pointed out that whereas the activities of the Trust in the past have necessarily tended to be sporadic, the time has now been reached when it can be assured of a substantial income and therefore has the opportunity to initiate a planned policy for spending its resources. To ensure such a longer-term policy and a more co-ordinated planning by the trustees, a full-time administrative staff is needed to deal with the charitable aspect of the Trust's functions, and Dr. F. H. K. Green, formerly principal medical officer on the headquarters' staff of the Medical Research Council, has been appointed scientific secretary of the Trust with the chief responsibility for the executive organization of its spending policy.

## Message for the Foreign Ministers at Geneva

On October 21, on the eve of the meeting of Foreign Ministers at Geneva now in progress, a public meeting was held in the Central Hall, Westminster, to give expression to the sense of urgency widely felt that there should be a fruitful outcome of the discussions. The meeting was sponsored by Earl Russell, Lord Boyd Orr and Prof. C. F. Powell, and a message signed by them and Sir Richard Coppock was sent to Geneva. In it they refer to the Geneva meeting as the natural successor of the July meeting of heads of States, and continue: "At this moment, so crucial for the future of man, we should like to bring to the attention of the Foreign Ministers the warning signed by some of the most eminent scientific authorities in different parts of the world, which dealt with the perils of nuclear war. That statement suggested that neither the public nor the governments of the world are adequately aware of the dangers facing the human race. We feel that statement still to be true; and that the Foreign Ministers need to approach their discussions with a deeper awareness of these dangers. The Foreign Ministers, like all of us, have to learn to think in a new way. They have to ask themselves how they can reach specific agreements on the problems before them so that they will rule out any military contest of which the result must be disastrous to all. . . . We wish to impress on them the view that agreements on one problem will improve the possibility of agreement on others; but that disagreement on any one problem should not rule out discussion and negotiation of others. On the question of Germany and European security, it is good that the governments have recognized that these problems are closely linked. There can be no stable peace while Germany remains disunited, but its unification must be brought about in a way which will not involve an important accession of strength to either East or West and will help to end the division of Europe into two hostile blocs. On the question of a disarmament plan involving reduction of conventional arms, the abolition of nuclear weapons and an effective scheme of control, the viewpoints of both sides now seem so close that agreement ought to be possible". Other matters mentioned are further measures for the exchange of visits and information, the easing of trade restrictions as a contribution to world economic stability, and the recognition of the Peking Government. The message concludes: "In making the cold war a nightmare of the past, the Foreign Ministers will have the support not merely of the peoples of both sides, but of the species Man".

## Humane Killing of Animals

The Universities Federation for Animal Welfare has issued a revised edition of its pamphlet, "Kind Killing", dealing with the humane killing of animals (pp. 28; from the Federation, London, 1955; 6*d*.). The booklet is particularly valuable because the author, Dr. Jean Vinter, realizes that in many circumstances the methods advocated may not be practicable. Sodium pento-barbitone, for example, is recommended for killing dogs and cats, but the most humane ways of shooting these animals are also described. Where this cannot be done, the best way of chloroforming is explained, as are the methods to be used in gas poisoning and electrocution. A separate note is included on the disposal of new-born kittens and puppies. Besides mammals, the pamphlet gives some useful hints on the killing of birds, reptiles, amphibians, fish and invertebrates which are nuisances or needed for dissection.

## 1955 "Science in Industry" Essay Competition

Seventy-seven entries were received for the 1955 "Science in Industry" Essay Competition organized by the *Sunday Times* and *Research*. The *Sunday Times* section of the competition proved to be the more popular, forty-three entries being received for it. The entries were remarkable for their diffuseness, and none was written in a style suitable for a newspaper appealing to the lay public. In consequence, no award was made. The standard of the *Research* section of the competition was a little higher. The first prize (£100) and the Waverley Gold Medal were awarded to Dr. F. Peter Woodford for an essay entitled "Living Reagents"; Dr. Woodford, International Wool Secretariat Postdoctoral Fellow in the University of Leeds, also received the special prize (£50) for the best entry from a competitor less than thirty years of age. The second prize was awarded to Dr. E. C. Potter, a physical chemist employed by the Central Electricity Authority, for an essay entitled "Corrosion in the Modern Power Station". Dr. Potter's essay will be published in *Research*.

## University of Birmingham

The following have been appointed to chairs in the University of Birmingham: Dr. D. G. Tucker, formerly senior principal scientific officer at H.M. Underwater Detection Establishment, Portland, to the chair of electrical engineering; and Prof. D. G. Catcheside, professor of genetics in the University of Adelaide (see *Nature*, 168, 234; 1951), to a chair of microbiology. The title of reader in chemical engineering has been conferred by the University on Dr. S. R. M. Ellis, and that of reader in pathology on Dr. D. B. Brewer. The following have been appointed lecturers: Dr. G. E. Brown (mathematical physics), Dr. G. Bullock (physical metallurgy), Dr. R. F. King (geophysics), J. Manhajm (mechanical engineering), Dr. W. T. W. Potts (zoology) and Dr. S. J. Taylor (mathematics). The following have been appointed to research fellowships: T. R. Carson (electron physics), B. W. Downs (mathematical physics), J. Graham (physical metallurgy), Dr. W. H. Holden (National Coal Board fellowship in chemistry), K. B. Mathur (Imperial Chemical Industries, Ltd., fellowship in chemical engineering), D. S. Rowe (experimental pathology), and Dr. W. I. Stephen (Imperial Chemical Industries, Ltd., fellowship in chemistry).

## University of Leeds

The University of Leeds has conferred the title reader in textile industries on Dr. H. N. Chamberla senior lecturer in rayon technology in the Departme of Textile Industries. The following have be appointed lecturers in the University: Dr. D. Armstrong (Brotherton research lecturer in physic chemistry); Dr. P. Gray (physical chemistry); I B. W. Langley (organic chemistry); R. D. Mack (civil engineering); and Dr. R. M. Tennent (physic

## University of London

The following appointments have been made the University of London: C. H. Barnett, seni lecturer at St. Thomas's Hospital Medical School, the University readership in anatomy tenable at th School; and Dr. R. S. F. Schilling, reader in t Nuffield Department of Occupational Health in t University of Manchester, to the University reade ship in occupational health tenable at the Londo School of Hygiene and Tropical Medicine.

## Announcements

Sir George Barnes, director of television, B.B.C since 1950, has been appointed principal of th University College of North Staffordshire, Keele.

Sir Herbert Manzoni, engineer and surveyor the City of Birmingham, has been elected chairma of the General Council of the British Standard Institution in succession to Mr. John Ryan, who ha completed his three-year period of service as chai man. Sir Roger Duncalfe, chairman of British Glu and Chemicals, Ltd., has been re-elected president o the Institution, and Sir Stanley Rawson, vice chairman of John Brown and Co., Ltd., has bee elected chairman of the Institution's Engineerin Divisional Council.

The following new appointments at the Brookly Botanic Garden, New York, have been announced Dr. Walter R. Tulecke, formerly of Arizona Stat College, research associate; Miss Gunny Larsson, o the Arctic Horticultural Research Station at Öjebyn Sweden, for one year as Ellen Eddy Shaw Fellow Miss Charlotte Mentges, of Frankfurt, Germany, t the educational staff.

Prof. John Wotiz, assistant professor of chem istry, has been appointed associate professor, an Maak-Sang Tsao, instructor of chemistry, has bee appointed assistant professor in the University o Pittsburgh.

Sir Bernard Keen, recently director of the East African Agriculture and Forestry Research Organization, has been appointed scientific advisor to Baird and Tatlock (London), Ltd., 14–17 St. Cross Street, London, E.C.1.

Messrs. Griffin and George, manufacturers of scientific apparatus, announce that, as from November 7, the Griffin and Tatlock Division at Kemble Street, Kingsway, London, will be closed: all correspondence should be addressed to Griffin and George, Ltd., Ealing Road, Alperton, Wembley, Middlesex (Tel.: PERivale 3344. Telegrams: Grifgeorge, Wembley).

Erratum. In the communication entitled "Site of Virus-like Particles in Rous Fowl Sarcoma Cells", by M. A. Epstein, in *Nature* of October 22, on p. 785, col. 2, line 3, the word 'are' should be omitted; it is the vacuoles which are visible by phase-contrast microscopy.

# TELEVISION AND FILM UNIT AT THE LONDON ZOO

THE Zoological Society of London, its Gardens at Regent's Park and its Park at Whipsnade have ways enjoyed a great deal of newspaper and radio ublicity. With the advent of the Independent elevision Authority (ITA) several programme-roducing companies have been formed, and some of hem have asked the Zoological Society of London grant them television rights. The Society takes he view, however, that it would be wrong to grant xclusive rights to any one company, and that it ould be equally impossible to have numerous com-anies working on the Society's premises, perhaps even at the same time, and disturbing its work. xclusive rights cannot be granted nor can a com-letely non-exclusive arrangement be contemplated. The Society has therefore decided to make the best ossible zoological material available and at the same ime to retain control of the Society's interests in elevision programmes and films, and to ensure that o responsible organization is denied the opportunity f broadcasting the programmes of its work. This will best fulfil the Society's policy of presenting its work to the public.

Of the several approaches made to the Society, all of which were carefully considered, that made by Granada was by far the most attractive and prac-icable. Granada proposed that the Society, in con-unction with Granada, should establish a permanent esident Television and Film Unit to produce pro-grammes for television, for the cinema, and for more pecific educational and scientific purposes. The Unit will be under the direction of a university-trained zoologist and will have at least two cameramen, perhaps more, preferably people with some scientific interest in zoology. It will cover all the work of the Society at Regent's Park, Whipsnade, on xpeditions abroad or wherever it may be necessary o go for special material. Its first function will be to provide the Society with documentary material, and it will be able to undertake long-term projects which may need a considerable period of time for their completion.

The Society looks to television for something more than revenue alone. It is the medium that can best project the Society's work and encourage the primary object of the Society's Royal Charter, granted in 1829, which is "the advancement of Zoology and Animal Physiology and the introduction of new and curious subjects of the Animal Kingdom" on a scale far beyond the possibilities previously available. The work of the Unit will fulfil these objects laid down in the Charter, and while it will not suffer from any lack of scientific integrity it will have a wide appeal to the public. The use of the new medium will do much more than exploit the easy entertainment value of animals; the possibilities for such a Unit are enormous and have never been grasped by any organization before.

In addition to its long-term projects and quarterly schedules of work, the Unit will keep a daily diary in picture and sound of events of special interest, new arrivals and so on, thus building up an extensive film and sound library for use in making programmes, educational and research films. Documentary matter needing the slow accumulation of material over months or even years will be recorded, and zoological expeditions to all parts of the world will also be an important part of the work of the Unit. Techniques to be used will include photomicrography, slow-motion cinematography, infra-red lighting and the 'hidden eye' to observe animal behaviour continuously over long periods.

The films will be available for production of television programmes and also for exhibition in cinemas, universities and schools. In addition, live broadcasts will be regularly produced. Granada will in general have first option; but the television programmes will be available to other users. Granada will distribute the programmes and films.

Under this arrangement the B.B.C., with which the Society has co-operated fully for many years, will be able to broadcast programmes of zoological interest in association with the new Unit.

---

# SMOKE ABATEMENT IN BRITAIN

## CONFERENCE IN BOURNEMOUTH

THE National Smoke Abatement Society may take credit for having provided for many years a platform on which discussion of the problems of smoke abatement have been given full scope. All elements of the community have in their turn been given their say. From year to year there have been heard the oft-repeated claims of the crusaders for cleaner air. For quite a few years careful research work and surveys of atmospheric pollution have been carried out by the Atmospheric Pollution Research Committee, and a conference of representatives of local authorities has been held under the ægis of the Department of Scientific and Industrial Research. One must not forget, too, the contributions to technical development, which have a bearing on these problems, made by a large body of scientists and engineers in fuel technology and resulting in a knowledge of how to burn fuel smokelessly. The Society's platform has again in these fields been the means of publicizing from time to time the painstaking efforts in technical development that must provide the basis of any really effective action in smoke abatement.

In this critical year of the Society's history, the Government's Clean Air Bill is likely to be debated. Accordingly, the proceedings of this year's annual conference of the Society, held in Bournemouth during September 28–30, are of particular interest. In keeping with past traditions, all aspects of the thorny problems to be faced have in some measure received attention, and opinions have been voiced which ought to reach the ears of the legislators. In his presidential address to the Society, Sir Ernest Smith rightly stressed the influence, in bringing about this situation, of the informed body of opinion into which there have been injected a large variety of ideas and much practical understanding by the activities of the Society. This is not to disregard the contributions made by that other large but silent body of expert opinion containing the practitioners of the technologies involved, who for upwards of a generation have provided a technical basis upon which smokeless combustion practice may be achieved. Without the 'know how' to burn fuel smokelessly, legislative action would be ineffective. The need at the present time is the problem of effective application of this existing knowledge.

The conference this year has provided interesting descriptions of recent progress in domestic heating by centralized methods, in particular of the Westminster City Council's district-heating scheme, considered from the financial, engineering and operational aspects. The scheme shows a saving of coal as well as an overall economy, a reduction of atmospheric pollution and improvement in domestic amenities.

Floor warming was an ancient practice known to communities as wide apart as the early Koreans and the Romans. To-day, with the application of electrical heating, the principle of thermal storage may be applied, the electricity being supplied to concrete flooring in 'off-peak' periods. Gradually, but surely, the hardy and reluctant dwellers of the British Isles are succumbing to the lure of the use of partial central heating, an interesting new feature of this practice being the application of forced circulation of hot water in small pipes—a result of research by the British Coal Utilization Research Association. All the heat from the boiler is kept within the living space of the house and is localized mainly in the radiators as the piping is so small. Another interesting article explains how the stuffiness of ducted hot air, another practice emanating from the Romans, may be safeguarded by suitable control of the movement of the air. The above are merely a selection of the many interesting points emerging from the technical discussions of the conference.

On the issues involved in the projected Clean Air Bill, opinions were many and comprehensive, ranging from contributions by the representatives of local authorities to several informative explanations of the purport of the Beaver Report by members of the Committee. These make much more intelligible reading than does the draft of the Clean Air Bill itself. Proverbially, the draft of a Parliamentary Bill in any case provides a form of mental persecution for the layman. The contributions to the Bournemouth conference give at least a clear indication of the intentions of the Report, and the reactions of much representative opinion from the local authorities. The views of the ordinary man and of the industrialist were unfortunately not heard; this is to be regretted, since they may be regarded in some respects as the victims for the sacrifice.

The objectives of the conference were, as would be expected, altruistic and worthy. The factors of practicability of some of the intentions may be quite another matter, about which, it is to be hoped, something may at last be heard in the debates in Parliament, if the victims have not become mesmerized by the certainty of a kill. Nevertheless, it must be agreed that now there looms before us some prospect of wise action which may contribute materially to a cleaner Britain that is so much desired by all. How much cause for thanksgiving may emerge in next year's conference.

R. J. SARJANT

# CAMBRIDGE ASTRONOMICAL SYMPOSIUM

THE symposium on "Astronomical Seeing", he at the Observatories, University of Cambridg during September 12–14, was timed to follow th General Assembly of the International Astronomic Union at Dublin, and thus to take advantage of th presence in Europe at this time of astronomers from all over the world. Its object was to provide forum for the exchange of ideas and informatio relating to the various aspects of the subject. Thes aspects include the accumulated knowledge of visu observers; the extensive *ad hoc* instrumental studie that have been made more recently, especially in th United States; the theory of scintillation, develope mainly with particular reference to radio problems and meteorological information about inhomogeneit and turbulence in the atmosphere. The aim was t provide time in the programme for sufficient dis cussion, so that progress could be made towards th resolution of real differences.

Dr. J. S. Hall (U.S. Naval Observatory, Washington, D.C.) described experiments in which correlation had been found between intensity scintillation in certain frequency-ranges and the speed of the uppe winds. Lamps attached to balloons showed les scintillation even at a height of 30,000 ft. than di stars observed at the same time; but it is probabl unsafe, he said, to conclude from the experiments s far made that appreciable seeing effects come from greater heights. Dr. Hall showed a film of shadow bands crossing the objective of the Washington 40-in telescope, and of extra-focal Hartmann patterns. Dr P. B. Fellgett (Cambridge Observatories) reviewed the physical theory of scintillation. Plane wave-fronts of starlight are diffracted by irregularities in the refractive index of the air, and the diffracted beams interfere to give phase- or amplitude-scintillation according to their mutual phases, which depend on the distance from the irregularities. Brightness-scintillation is usually negligible just below the irregularities, and increases with distance, while phase scintillation decreases slightly. The complex autocorrelation function of the amplitude across the mean direction of travel remains constant; and the mean intensity distribution in a telescopic image is also independent of distance from the source of disturbance. The spatial frequencies in the scintillation differ in general from those in the irregularities of refractive index. Dr. A. Hewish (Cavendish Laboratory) presented quantitative results for some chosen cases. He showed calculations and slides of the detailed development of brightness changes beyond sinusoidal phase-changing layers of various amplitudes; of the interchange between brightness changes and phase-scintillation; and of the corresponding autocorrelation functions of complex amplitude, showing the dominance of harmonics of the layer-frequency when the phase change is large. The corresponding statistical developments were shown for a layer having a Gaussian autocorrelation function of refractive index.

Dr. G. Keller (Perkins Observatory, Ohio) gave a detailed account of work at the Perkins Observatory. Observations have been made of the temporal power-spectra of brightness changes for various telescope apertures; the correlation of scintillation in certain frequency-ranges with upper-wind speed; correlation of upper-wind direction with the dependence of cintillation, observed through a slit covering the bjective, on the position-angle of the slit; and the egree of coherence between scintillation in selected requency-ranges observed in two neighbouring pertures. Dr. W. H. Steavenson (Cambridge) dis- ussed the effects which can be distinguished visually n extrafocal images or when the eye is placed at the ocus of the telescope. The 'high seeing' appears as hadow patterns blown at high speed across the perture, and defocusing experiments indicate an verage height of origin of about 10 km. Slower hadow bands originating within a few hundred feet f the telescope can be seen to move with the surface vind. Local dome and tube effects are recognizable y their geometry. In large reflectors, the cooling of he mirror causes disturbances in the thin layer of ir at the face of the mirror; these are much more erious than the well-known changes in mirror sphericity and can often be the dominant cause of mage spread. Dr. A. Hynek (Ohio State University, Columbus) reported studies of image motion made by Dr. A. G. Wilson at Flagstaff, Arizona. Star-trails recorded on fast-moving film showed the amount of movement, the proportion of the time that the image is sharp, and the occurrence of multiple images. These studies were made with special reference to the design of methods of photographing Mars, and an important conclusion is that at Flagstaff the instantaneous image movement is nearly the same over the whole disk of the planet. Dr. Hynek also reported some very recent work at Ohio State University which included measures of image movement in two colours. If image-spread were an effect of rapid image motion, this might provide a further test of the remark of Hewish and Keller that the red images may be expected sometimes to have a sharper 'core' than the blue.

Dr. B. H. Briggs (Cavendish Laboratory), describing radio observations of the scintillation at neighbouring wave-lengths, said that in the ray-interference approximation the correlation across the spectrum is simply related to the spread in the ray path-lengths between the source and observer. Rapid frequency-change experiments yield records similar to the spectrum-scintillation photographs of Zwicky, and the problems of interpretation are also similar. Dr. E. H. Linfoot (Cambridge Observatories) took up the question of measuring the harm done by bad seeing. Seeing effects reduce the rate at which a given telescope can record information about the sky. The loss can be estimated in terms of the mean transmission factors (sine-wave response factors), which are essentially equal to the mean autocorrelation function of the complex displacement across the aperture. Dr. Linfoot showed how the reduction in information capacity (in Shannon's sense) can be calculated from the statistics of seeing; generally speaking, the loss is of second order when the phase-errors are small. Dr. R. Goody (Imperial College of Science and Technology, London) presented meteorological data on turbulence and convection in the atmosphere. By day, in clear weather, convection is most intense near the ground and falls rapidly throughout the first 1,000 ft. Convection is enhanced over large mountains and islands. A small island should have good daytime seeing, and even a few feet of height above the ground could be beneficial. Aircraft results show inhomogeneities at various heights. A few accelerometer records from balloon flights show increased turbulence near the tropopause, but it is not known whether this is typical. The northern edge of the jet stream in the northern hemisphere is sometimes very turbulent. Generally, however, the atmosphere is non-adiabatic and is continually being mixed, so that the causes of seeing effects are unlikely to be confined to any narrow range of height.

In the discussion, widely different opinions were expressed about the usefulness of the ray approximation to the Huyghens wave treatment. One view is that ray theory is adequate under suitable conditions for small phase perturbations. It was urged in reply that ray theory is essentially the limit of wave theory as the wave-length becomes very small compared with the relevant geometrical path-differences, so that it is expected to be valid (as in aberration calculations) only for large phase-changes. It was the general opinion that the phase-changes corresponding to good seeing could be of the order of a few radians, but the lack of any specific measurements of this fundamental quantity illustrates how much is still to be learnt. It was pointed out that the combined effect of spatial smoothing by the objective aperture, and temporal smoothing in the electrical filters, would in general make the amount of scintillation recorded photoelectrically dependent on the transverse speed of the shadow bands. Until this is allowed for, it cannot be said whether the observed wind-scintillation correlation represents an actual physical connexion between wind-speed and optical inhomogeneities in the air. Non-isotropic inhomogeneities would necessarily give rise to telescopic images that are not radially symmetrical, although this effect might be masked by disturbances originating at another height. It was suggested that the height of origin of scintillation could be found in principle from the cross-over wave-length in the colour scintillation; from the ratio of phase to brightness-scintillation at different wave-lengths; and by the analogue of the spaced-receiver experiments of Briggs *et al.*, the linear transverse velocity being found from the correlation of scintillation in two apertures and the angular velocity by observations of two neighbouring stars. A plea was made for observations in narrower wave-length ranges.

---

# HUNGARIAN–CZECHOSLOVAK POLAROGRAPHIC CONFERENCE

FOR the first Hungarian–Czechoslovak Polarographic Conference held in Veszprém, Hungary, during August 11–14, seventeen Czechoslovak polarographists, mostly from the Polarographic Institute of the Czechoslovak Academy of Science, were guests of the modern Chemical University in Veszprém at the meeting arranged jointly by the University, the Hungarian Chemical Society and the Hungarian Academy of Science. Prof. J. Heyrovský was the leader of the Czechoslovak delegation; from the Hungarian side, Dr. Polinszky (dean), Dr. Preissich (secretary of the Chemical Society), Dr. Cieleszky (chairman of its Polarographic Section), and Prof. Bognár (general secretary of the Hungarian Academy) organized the Conference extremely successfully. The Minister of Education, Prof. Erdey-Grúz, a prominent physico-chemist, was in the chair. At the opening of the Congress, a diploma of honorary fellowship of the Hungarian Academy of Science was presented to Prof. J. Heyrovský, who then delivered an address on the "New Trends in Polarography". Prof. L.

Erdey addressed the general assembly on the "Development of Polarography in Hungary".

The forty-six communications that followed were divided into two parallel sections, one for applications in inorganic analysis, the other for biochemistry and biology. Lectures and discussions were in German, English, French, Hungarian and Slovak. General oscillographic polarography was discussed at a conjoint meeting by J. Heyrovský and quantitative oscillography by R. Kalvoda, who demonstrated their specially constructed cathode-ray oscillographs. As innovations may be mentioned: polarographic estimations of chromatograms (J. Proszt and J. Kis), automatic polarographic analysers of long duration (J. V. A. Novák), streaming of electrolytes induced by alternating currents (J. Dévay), derivative currents obtained by electromagnetic induction (J. Proszt and J. Paulik), deposition of magnesium at the streaming electrode (K. Győrbiró, L. Poós and J. Proszt). In the biological section, several communications concerned Brdička's protein test, the determinations of vitamins, oxygen in tissues, alkaloids and many applications in pharmacy and food production, and the study of macromolecules by means of suppression of maxima.

The communications will be published in full in German by the Hungarian Academy of Science in a special volume. Brief abstracts of the papers may be obtained through Dr. E. Bodor, Chemical University, Veszprém, Hungary.

It should be added that Veszprém lies close to the famous Lake Balaton, on the banks of which the delegates enjoyed discussions for several days after the Congress. J. Heyrovský

# NATIONAL PHYSICAL LABORATORY, TEDDINGTON

## REPORT FOR 1954

The annual report for 1954 of the National Physical Laboratory, Teddington*, consists of the report of the Executive Committee which was presented to the General Board at its meeting during the afternoon of May 20, 1955, the annual open day of the Laboratory (see *Nature*, 175, 1102; 1955), and detailed reports, prepared by the respective superintendents, of the work of the nine divisions and Test House of the Laboratory.

The Executive Committee refers with particular pleasure to the visits of Their Majesties the King and Queen of Sweden on June 29, and of the members of the Royal Commission on the Civil Service on May 12. Other visitors during the year included parties from the Royal Naval College, Greenwich, and delegates from the joint spring meeting of the Institute of Metals with the Société Française de Metallurgie, and from the General Assembly of the Internationl Union of Pure and Applied Physics. A thirty-minute television outside-broadcast directly from the Laboratory took place on June 2, and the work of the Laboratory, with special reference to aerodynamics research, was also described in a schools' broadcast on October 27. In addition, the director of the Laboratory, Sir Edward Bullard, took the leading part in a studio programme, entitled "Power from the Sun", which was broadcast on October 11.

At the beginning of the annual report, the name of the members of the General Board, the Executive Committee, the Promotions Sub-Committee, the Froude Ship-Research Sub-Committee, and a newly constituted body, the N.P.L. Advisory Committee on Radioactive Standards, are listed. The new Committee formerly existed as an informal body, consisting of representatives of the Atomic Energy Research Establishment, the Radiotherapeutic Research Unit of the Medical Research Council, the Royal Cancer Hospital and the National Physical Laboratory; Dr. B. W. Robinson, superintendent of the Physics Division of the Laboratory, was appointed chairman of the Committee. In order to make the work of the Laboratory better known to industry, two liaison officers were appointed during the year for a three-year period, and it is reported that they have visited thirty-two research associations and have made direct contact with a number of industrial firms. The new building for the Metallurgy Division, which contains the refractories section, the X-ray section and laboratories for work on radioactive tracers, was formally opened by Sir Lawrence Bragg on April 6, and in June a new Division, that of Control Mechanisms and Electronics, was formed by amalgamating the control mechanisms section of the Metrology Division with the Electronics Division. The field of work to be covered by the new Division is a wide and important one, dealing with the automatic control of experimental, industrial and administrative operations and the development techniques and equipment for data-processing and computation; but, at present, work is to be restricted to a continuation of that previously carried out by the two original sections.

The Laboratory took part in several exhibitions of scientific apparatus, including the Physical Society annual exhibition, the Royal Society soirées and a conversazione arranged by the Institution of Civil Engineers. Two international symposia were held during the year at the Laboratory, one in May on "Creep and Fracture of Metals at High Temperatures" and the other in November on "Precision Electrical Measurements". The proceedings of the symposium on "Automatic Digital Computers", held in March 1953, and four new booklets, Nos. 5–8, in the series "Notes on Applied Science" were published during the year. In addition, one hundred and forty-six scientific papers were contributed by members of the staff of the Laboratory to various journals and periodicals; lists of these are appended to each detailed divisional report.

The individual reports of the various divisions of the Laboratory indicate the wide range of scientific subjects covered. The Laboratory has, in addition to an extensive research programme, part of which is paid for by other government departments, certain specific responsibilities, including the maintenance of standards and routine test work. It would appear that the programme contains more items than are really desirable, and a reduction in the number in order to enable more rapid progress to be made with the remainder, and perhaps also to commence on a few new urgent items specially appropriate to the Laboratory, is being considered. The Aerodynamics Division has carried out important work on the application of boundary-layer control to the reduction of drag and the increase of lift. Helicopters appeared on the research programme of the Division for the first time, and a twin-rotor model for wind-tunnel tests was being made. Some fundamental work con-sting of high-speed tunnel experiments on the flow f air at supersonic speeds over elliptic cones has ready received practical application in the behaviour f high-speed aircraft and the use of highly swept ings.

* Department of Scientific and Industrial Research. National Physical Laboratory: Report for the Year 1954. Pp. viii+98+7 plates. (London: H.M.S.O., 1955.) 4s. net.

In the Control Mechanisms and Electronics ivision work has continued on digital computers, nalogue computers and data-reduction devices. Two magnetic-drum stores have been installed on the ilot model of the automatic computing engine ACE); an enlarged and improved version of the lectronic simulator has been put into service and used in conjunction with the London School of Economics for an extensive study of economic systems; and, at the request of the Committee on High-speed omputers of the Department of Scientific and Industrial Research, a group was formed in May to study he mechanization of large-scale clerical operations y means of electronic-digital techniques and equipment. A new impulse generator for 3·2 MV. was installed during the year in the high-voltage section of the Electricity Division, and, in connexion with its work on frequency standards, a highly stable oscillator controlled in frequency by a cavity resonator has been developed by the Division. Steady progress was maintained with the cæsium atomic-beam standard.

The Light Division has spent several years developing methods for the production of diffraction gratings using techniques suggested by Sir Thomas Merton. The stage has now been reached where good-quality and reasonably sized gratings, suitable for use in research and industry, can be produced comparatively cheaply. Work on the application to the control of machine tools of the system of moiré fringes which is formed when two identical diffraction gratings are superimposed with their rulings nearly parallel has also been actively pursued. The Metrology Division reports considerable progress in the development of autocollimation and pneumatic gauging as a means of making highly accurate dimensional measurements for research and industry, and mention is made of the machines that have been built in the Laboratory to measure bore diameters of 0·1–6 in. to an accuracy of ± 0·000 01 in., in addition to an apparatus to measure the diameter of wire as fine as 0·000 2 in. to a similar accuracy. A new absolute determination of gravity, in which the free up–down motion *in vacuo* will be timed, is envisaged, in order to improve the accuracy of measurement of barometric pressure and hence the steam point, and some preliminary work has already been done on the proposed interferometric method for measuring the distance over which the motion is to be observed. Consideration is also being given to the construction of a transportable primary-standard barometer for additional improvement of the precision of realization of the temperature 100° C.

In the Metallurgy Division an investigation of the processes taking place during the fatigue of metals has been started, and in the study of intercrystalline fracture of ion alloys and certain copper alloys at low temperatures some remarkable results have been obtained. A comprehensive report was issued in October 1954 giving results of creep tests lasting up to ten thousand hours (more than a year) on steels to be used in the British Electricity Authority's new power stations. The Physics Division has co-operated in an international comparison of three resistance thermometers, constructed at the United States National Bureau of Standards, Washington, D.C., the Institute of Metrology, Leningrad, and the National Physical Laboratory, respectively, and its acoustics and sound measurement section has given assistance with a form of acoustical treatment designed by the Building Research Station for the stonework of the new Coventry Cathedral. The radiology section has constructed a new free-air ionization chamber for use with X-rays generated up to 300 keV. Features of the new chamber are that it is of the guarded-field type and that the air pressure and the potential of the case relative to that of the electrode system can be varied. The Mathematics Division has devoted most of its time to the solution of problems for industry and other government departments, using the pilot model of the automatic computing engine, and one of the largest problems tackled has been the analysis of stresses set up in the steam-catapult retardation structure in H.M.S. *Ark Royal*. An interesting development reported by the Ship Division is that tests were undertaken for the first time during the year on sailing yachts. Considerable assistance in other connexions has also been given by this Division to the Yacht Research Council.

Finally, the annual report, which is presented with an attractive cover and is illustrated, concludes with a report of the Test House and with a list of the senior staff of the Laboratory, arranged according to the various Divisions.

# EDUCATION IN ENGLAND AND WALES DURING 1954

THE report of the Ministry of Education on "Education in 1954"* gives statistics for primary and secondary education in England and Wales and for university awards and further education during the year; but the section on advanced technological education in technical colleges continues to display the confusion in which technological education still lies and which the institution of a new award recently announced by the Minister does nothing to remove. The number of children in the maintained schools increased by about 120,000 in 1954 and will continue to grow, but by decreasing amounts, until 1958. The number of children in the infant schools had already started to decline by the beginning of 1954; but the secondary schools will not receive their largest increase in numbers until 1958, and the peak will be reached at the end of 1960. The provision of additional places in secondary schools is well in hand: of some 210,000 new places brought into use during the year ended October 1, 1954, 75,000 were in secondary schools, while a further 200,000 places were under construction; and the building programme for 1954–55 is providing some 120,000 places in secondary schools out of a total of 187,000.

The number of teachers increased by 6,100 in 1953, and for 1954 the increase is estimated as more than seven thousand, while the entry of 11,768 students for two- or three-year courses at training colleges was the highest recorded. Generally, the staffing position tended to improve during the year; by 1961 at latest, nearly all primary-school classes should be reduced to the regulation size of forty pupils or less, and in the secondary schools over the same period it should be possible to maintain the present staffing standards, which are appreciably better than those of five years ago. The supply of graduate teachers of mathematics and science has continued to cause serious concern, quality rather than quantity being the deficiency in 1954; but difficulty is anticipated in recruiting even a sufficient number of these teachers to meet the growing needs of the secondary schools. Sir David Eccles, in his introduction to the report, refers to the action he has taken to see whether existing salary scales for such teachers engaged in more responsible or advanced work are adequate for their purpose and likely to lead to the needs of the schools being properly met, and also to the consultations with the universities, industry and other departments as to the possibility of restraint in the recruitment of graduate scientists. This approach has been deprecated by the Advisory Council on Scientific Policy in its subsequent report, but no other proposals are made for meeting the shortage, although area training organizations and colleges have considered the possibility of increasing the output of non-graduate teachers able to take some part in teaching science and mathematics, especially in secondary modern schools. The main difficulty has proved to be one of suitable candidates. The National Advisory Council on Education for Industry and Commerce was asked to examine the requirement for trained technical teachers, and on its advice the Minister decided to retain the technical training colleges in Bolton, Huddersfield and London.

---

* Education in 1954: being the Report of the Ministry of Education and the Statistics of Public Education for England and Wales. Pp. viii+197. (Cmd. 9521.) (London: H.M.S.O., 1955.) 7*s.* 6*d.* net.

The National Advisory Council submitted revised proposals for a national award in advanced technology and has also paid particular attention to the development of sandwich courses, which it discussed with the Federation of British Industries. Although during the year another 113 advanced courses at technical colleges were approved for the special 75 per cent grant (making a total of 493) and the number of advanced short courses for scientific workers and technologists already employed in industry was practically doubled, it is clear that the confusion between technical and technological education persists; and that the proposal to develop ultimately some thirty technical colleges into advanced regional colleges carries grave risks of spreading available resources too thinly to be effective even if staff of the requisite calibre can be attracted. Building projects to the value of more than £7·5 million were completed during 1954 at further education establishments, out of a total £58,858,000 completed. The Minister announced at the end of the year an increase for 1955–56 of £2·5 million in the annual building programme for technical education, as well as the relaxation of certain restrictions on the type of course for which new technical college building can be approved. At the same time, he emphasized the need for continued economy in educational expenditure and for giving priority to certain selected projects if the new advances are to be made good and delay avoided in proceeding to further advances.

More than fourteen thousand students entered universities and university colleges in 1954 with financial assistance from public funds, and further progress is reported towards more uniform practice among local education authorities in standards of selection and in rates of grants. Thirty State scholarships were again offered for mature students, and, since these arrangements were instituted in 1947, 204 such scholarships have been awarded, mostly in English, economics and politics, but in recent years increasingly in natural sciences and mathematics. Referring to Colonial students, the report states that in 1954 the training colleges accepted 161 students from twenty different Colonial Territories and also found places for four students from the Sudan and twelve from Iraq and for seventeen Colombo Plan scholars. There is ample evidence that the experiment of training Colonial teachers in training colleges in Great Britain is proving a success: the students are well liked and hard working, and seem to enjoy the life and work of the colleges. Exchanges of teachers with Commonwealth countries and the United States only totalled eighty-eight (eighty-six in 1953), and only eleven went to European countries (nine to France, one to Germany and one to Austria).

The report also covers the Victoria and Albert Museum and the Science Museum, London, noting that completion by 1960–61 of the Centre Block of the Science Museum building will have accomplished the second of the three stages of development recommended by the Bell Committee in 1912. Issues in the Reading Room of the Science Library were 26,002, compared with 25,241 in 1953; requisitions for external loans rose from 94,772 to 101,683, and 176,960 photocopy sheets were issued compared with 157,894 in 1953. On the major issue of a science centre and the project for a national lending library of science and technology, the report is silent.

# ELECTRON MICROSCOPIC OBSERVATIONS ON THE STRUCTURE OF THE SIEVE PLATES IN *CUCURBITA*

By C. E. L. HEPTON, PROF. R. D. PRESTON, F.R.S., and G. W. RIPLEY
Department of Botany, University of Leeds

THE movement of solutes through the phloem of plant stems has long been an object of intense study and has produced a voluminous literature. In spite of this, however, it cannot be claimed that any of the proposed mechanisms of transport are any more satisfactory now than they were when first suggested. The explanation is not far to seek. It is generally agreed that translocation occurs along the sieve tubes at rates which are enormously higher than could possibly obtain by diffusion alone. Whether these rates are achieved by convection (for example, mass flow) or by some kind of 'activated' diffusion (for example, movement at an interface) the major barrier to flow occurs in the sieve plate, and it has become very clear that further advances must await a thorough elucidation of the structure of this plate

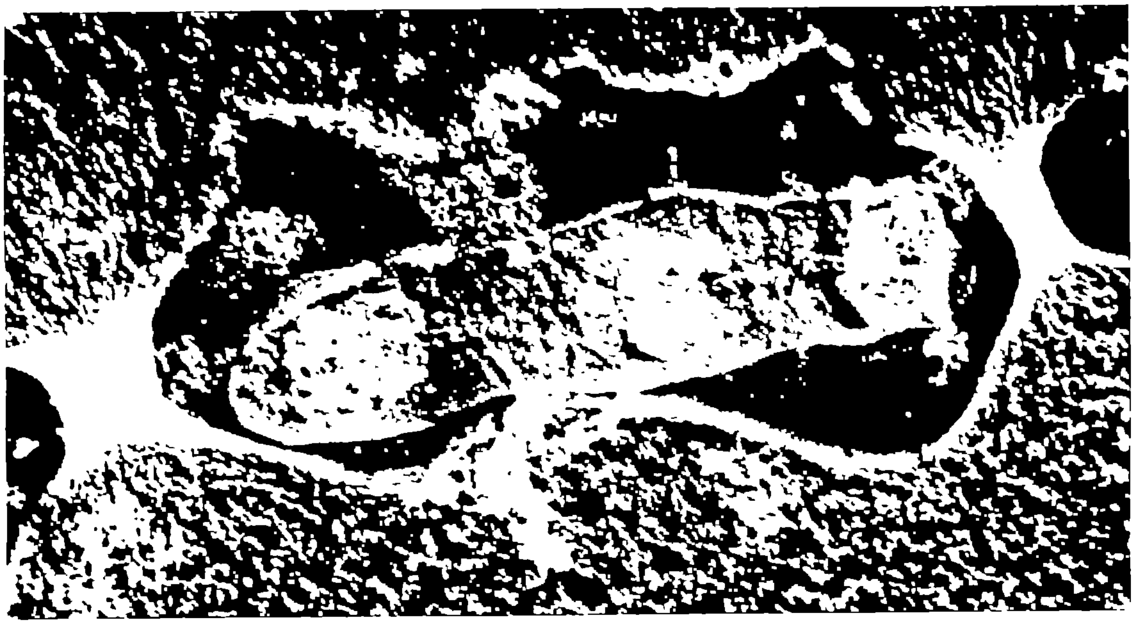

Fig. 1. Longitudinal section through sieve plate of young *Cucurbita* stem. Shadowed palladium-gold, magnification 18 700 ×. Note the two pores on either flank cut in almost median section; the position of a third pore, out of section, may be detected in the centre

and, in particular, the nature of the content of the sieve pores. This has been emphasized in a recent discussion of the structure of phloem in terms of its functions[1].

We have now completed a series of preliminary observations on the sieve plates of *Cucurbita* which we consider to represent a distinct advance of sufficient importance to be recorded at this time. Pieces of stem 4–5 in. long cut from young plants growing in a greenhouse were immersed for two hours in 0·3 *M* sucrose. This treatment was intended to reduce the turgor pressure in the sieve tube elements and hence to minimize slime plug formation, following the method of Currier, Esau and Cheadle[1]. Separate vascular bundles were then dissected from a central piece about 1 cm. long and fixed in a 1 per cent solution of osmic acid in a veronal-acetate buffer at *p*H 7·25. After washing in buffer solution for two hours they were imbedded in the usual way in a mixture of 10 parts butyl and 3 parts methyl methacrylate. Ultra-thin sections, both transverse and longitudinal, were cut on a Hodge-type microtome made in this laboratory. The methacrylate was removed by passing the sections through amyl alcohol and amyl acetate and the preparations shadowed with palladium-gold. These sections are all of sieve tubes which we presume to be functional.

The transverse sections of sieve plates are not presented since they are not of a quality to yield any new information. They do, however, substantiate as

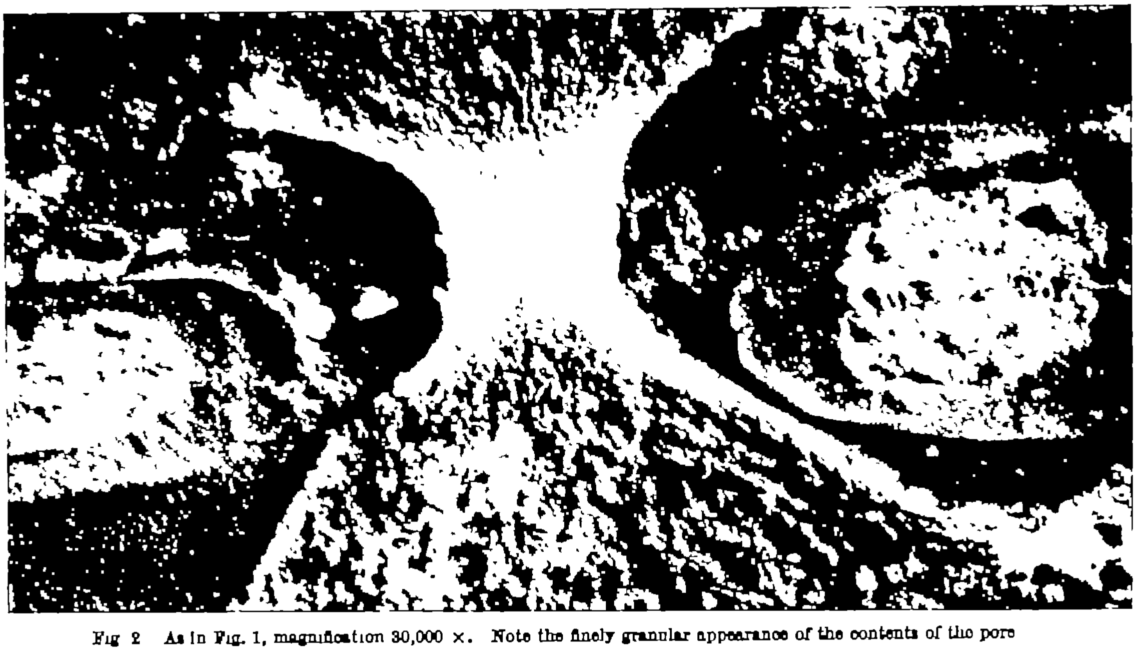

Fig 2 As in Fig. 1, magnification 30,000 ×. Note the finely granular appearance of the contents of the pore

fully as such sections can the diagrammatic representations made by Esau[2], namely, that the pores appear to be plugged with material confluent with what appears to be the cytoplasm of the sieve tubes. Representational longitudinal sections, however, which were much more successful and are in any event more likely to yield critical information, are illustrated in Figs. 1 and 2.

Examination of these photographs leads to several important conclusions:

(1) The cytoplasm is continuous from one sieve tube to the next through the sieve pores. The contents of the pores are withdrawn from the pore walls; but this is probably an artefact induced largely by the pretreatment with the sugar solution. It would seem that in Nature the pores are completely plugged. This at last confirms the suspicion voiced by various workers (for example, Crafts[3]) based on much less adequate observation under the light microscope.

(2) There is no continuity of vacuole across the sieve pores. Although the cytoplasmic strands have collapsed, this can scarcely have been due to collapse of a hollow tube, for in that case we would have expected to observe the vacuole opening out on each side of the pore into that of each of the contiguous elements.

(3) The wall of the sieve plate has itself an unexpectedly complex structure. We do not wish at the moment to comment further upon this.

(4) There appear to be few or no micro pores through the walls as large as 200–300 A. as postulated by Crafts[3] in a recent review. The shrinkage of the cytoplasm in the pores makes it difficult to assess the probable condition in untreated material, so that the size of any presumptive micro pores here remains an open question.

Space will not permit a complete analysis of these findings in terms of translocation mechanisms even if this would be profitable at this time. It may, however, be pointed out that even this preliminary work may reasonably be interpreted as demanding a new approach to the problem. The mass flow hypothesis of Münch[4] postulates a continuity of vacuoles from sieve element to element as part of the flow path. This is now demonstrably erroneous, and, in view of the fact that mass flow of the whole cytoplasm is difficult to conceive, the complete hypothesis as first formulated must fall. The attempts made by Crafts[3] to meet this eventuality, by assuming the existence of capillaries in the cytoplasm of the pores of the order of 200–300 A. wide, seems to be on no safer ground even if such pores could be shown adequate to cope with the solute movement. In any event, a simple calculation shows that, even assuming Poiseuille flow in such fine capillaries, the pressure gradient across the thickness of the sieve plate would need to be so high as to be inconceivable.

Similarly, the intervention of cytoplasmic streaming championed by Curtis[5] can scarcely be considered any longer feasible even on anatomical grounds alone. For unless the cytoplasm streams through the pores—demanding a complex and carefully regulated two-way flow which seems highly unlikely—the rate of movement would then be limited by diffusion through the pores. Most workers seem, moreover, to doubt that streaming occurs in mature functioning sieve tubes. Finally, the diffusion at an interface discussed by Van den Honert[6] meets with the difficulty that the only continuous interface available is a solid–liquid interface. Movement at such interfaces is known to be much too slow to account for the measured rates of solute transfer.

It could therefore be that the time has come to discard mechanisms which are fundamentally purely physical. A recent paper by Kursanov[7] emphasizes the probable role of metabolic factors in solute transport in phloem; we can only add that the apparent continuity of the cytoplasm suggests strongly that vital processes play a more important part than is sometimes assumed.

# SPECIFICITY IN CHEMICAL AND ENZYMATIC OXIDATIONS OF GLUCOSE ANOMERS

By DR. RONALD BENTLEY

Department of Biochemistry and Nutrition, Graduate School of Public Health, University of Pittsburgh, Pittsburgh 13, Pa.

THE chemical oxidations of glucose[1,2] and methyl glucosides[3] to gluconic acid are often more rapid with the β- than with the α-anomers. The reagent most extensively studied is bromine in solutions buffered at about $pH$ 5·4[4]. Under these conditions, the pyranose ring is converted first to δ-gluconolactone in high yield. Gluconic acid is then formed by slow hydrolysis of the lactone. The ratio of the rates of oxidation at 0° is $\beta : \alpha = 39{\cdot}2$, and similar increased reactivities are found for the β-forms of a number of pentoses, hexoses and disaccharides[2].

Elucidation of the mechanism of these reactions should have an important bearing on the biochemical oxidations of glucose, for which an even higher order of specificity exists. In one such enzymatic oxidation, using notatin (glucose aerodehydrogenase), it was shown that, like the chemical reaction with bromine, the initial product is δ-gluconolactone; further, the reaction is more rapid with β-glucose[5]. It has now been demonstrated unequivocally that the specific substrate of notatin is β-D-glucopyranose[6]; α-D-glucose is oxidized at about the rate of other sugars and the ratio of rates in this case is the highest yet observed ($\beta : \alpha = 156$). An analogous case is that of the glucose dehydrogenase isolated from ox liver, which is also specific for β-D-glucose[7]. Glucose

-phosphate dehydrogenase similarly produces 6-phoshogluconolactone from the Robison ester[8]; the ynthesis of this ester by catalytic saponification of : 2 : 3 : 4 - tetraacetyl - β - D - glucose 6 - phosphate[9] trongly suggests that in this case, too, the enzyme s specific for the β-anomer.

In this communication, an attempt will be made to interpret these chemical and enzymatic specificities in terms of a conformational analysis similar to that developed in the case of *cyclo*hexane and other alicyclic compounds. Such an analysis indicates that the hydroxyl group on carbon atom 1 of α-glucose is in a sterically hindered position, and that reactions directly implicating the hydroxyl group will take place more readily with β-glucose. Mechanisms for the chemical and biochemical oxidations will be discussed in the light of stereochemical considerations.

## Conformation of Glucose

Although the possibility of strainless 'chair' and 'boat' forms of the pyranose ring was recognized by Haworth[10], glucose is usually represented in the Haworth perspective formula as a (strained) planar structure, the substituents being considered as above or below the plane of the ring. In 1947, Hassel and Ottar[11] discussed the structure of molecules containing *cyclo*hexane or pyranose rings and stated that: "All experimental evidence indicates that the six-membered pyranose ring found in many sugars will generally have the staggered form corresponding to the symmetrical *cyclo*hexane ring", that is, to the 'chair' form. The possible conformations for pyranoses were considered in detail by Reeves[12], who concluded that in the case of D-glucose the most stable conformation was that indicated as C1 in Fig. 1. The alternative 1C structure (which is derived from C1 by ring conversion[13]) contains more 'instability factors'. Hassel and Ottar further pointed out that if the pyranoses existed in such 'chair' forms, the substituents would occupy either the axial (*a*) or equatorial (*e*) position as in the case of the *cyclo*hexane derivatives (in this communication, the recently recommended nomenclature of Barton *et al.* will be used[14]).

These considerations have been borne out in detail by X-ray analysis of the crystal and molecular structure of α-D-glucose[15]. The pyranose ring is found to be six-membered in the 'chair' conformation and with the predicted *cis*-glycol grouping on carbon atoms 1 and 2. Although this proof of the 'chair' conformation (C1) is conclusive only for the solid state, this most stable conformation almost certainly persists in solution, as the work of Reeves indicates[12]. More accurate representations for the glucose anomers therefore are the formulæ (I) and (II) for α- and β-glucose respectively (Fig. 2). In α-glucose, the hydroxyl on carbon atom 1 is in an axial position, all the other hydroxyls and the primary alcohol group being equatorial. In β-glucose, all the hydroxyls and the primary alcohol group are equatorial. Differences in the infra-red spectra of α- and β-anomers have recently been observed and related to the fact that the hydrogen atom in the α-anomer is in the equatorial position[16].

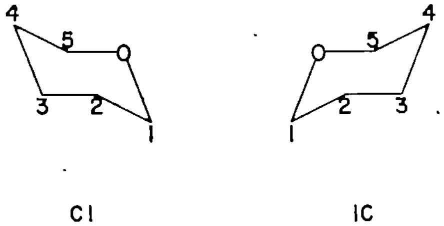

Fig. 1. Chair conformations of the pyranose ring. (These conformations have been redrawn from those of Reeves (ref. 12) so that the position of the oxygen atom in C1 corresponds with that in the conventional Haworth formulæ

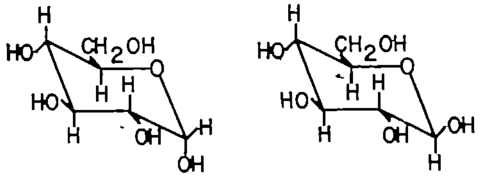


(I) (II)

Fig. 2. Conformations of α-glucose (I) and β-glucose (II)

## Reactivity of Axial and Equatorial Groups in Glucose

It was pointed out by Barton[17] that, because of their more crowded nature, axial groups in alicyclic compounds would tend to be hindered in their chemical reactions. (Examples of compounds sterically hindered in this way have been summarized recently by Klyne[18].) By analogy, therefore, the axial hydroxyl group at carbon atom 1 in α-glucose would be expected to be less reactive than the corresponding equatorial hydroxyl group in β-glucose. This greater reactivity of β-glucose should also extend to compounds in which the hydroxyl group is substituted. There is, indeed, much evidence to show that derivatives of β-glucose are the more reactive, and the following examples are cited in support of this contention.

(*a*) Acid hydrolysis of β-methyl-D-glucopyranoside is almost twice as rapid as that of the α-glucoside[19]. For most glycosides a similar increased rate of hydrolysis of the β-anomers is observed (for examples, see Pigman and Goepp[20]). A notable exception to this generalization is the case of the methyl-D-gulopyranosides, where the α-anomer is more readily hydrolysed. A possible explanation is the anticipated[12] conformational instability of the C1 structure for D-gulose; in the 1C alternative, the α-hydroxyl on carbon atom 1 would be equatorial.

(*b*) The reductive cleavage of β-benzyl-D-glucopyranoside tetraacetate to 2 : 3 : 4 : 6-tetraacetyl-β-D-glucopyranose takes place rapidly and smoothly in dry ether with a palladium catalyst[21]. The corresponding α-derivative is cleaved with difficulty and only incompletely. Similarly with the benzyl-D-xylopyranoside triacetates, the reaction is more rapid with the β-anomer. Since D-xylopyranose has the C1 conformation, this is comparable to the case of D-glucose. With benzyl-D-arabinopyranoside triacetates, the reverse ratio (α > β) was observed. This is in harmony with the postulated 1C conformation for D-arabinose[12], where the α-hydroxyl would be equatorial. Unfortunately, comparable data for the α- and β-benzyl-L-arabinopyranoside triacetates (where the conformation is C1 and where the cleavage of the β-compound should be the more rapid) were not recorded.

(*c*) Only phenyl-β-glucoside reacts with aqueous alkali to form 1 : 6-anhydroglucose; after two weeks boiling of the α-form with 2·6 *N* potassium hydroxide, there was no rotational change, and 85 per cent of the starting material was recovered in crystalline form[22]. Since this reaction is believed to require the formation of a 1 : 2-anhydride[23], the reaction would take place more readily with the di-equatorial (β) than with the axial-equatorial anomer (α).

(*d*) Differences in stability of the pentaacetyl-D-glucopyranoses[24] also point to the hindered nature of the α-acetoxy group. Thus the reaction of the β-anomer with titanium tetrachloride is very fast, producing (initially) tetraacetyl-β-D-glucopyranosyl chloride. The α-anomer, on the other hand, is very stable under these conditions.

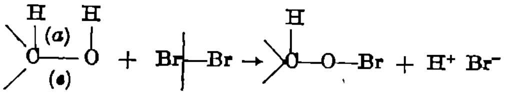
## Mechanism of Chemical Oxidation of β-Glucose with Bromine

Although, therefore, in the reactions of the type $—OH \rightarrow —OR$ or $—OR \rightarrow —OH$, *cyclo*hexane and glucopyranose compounds react most readily when the reagent attacks an equatorial substituent, an apparent exception to this generalization exists in some oxidations of the type $=CHOH \rightarrow =CO$. Barton pointed out[17] that the oxidation of some *cyclo*hexanols (to *cyclo*hexanones) with chromic acid in acetic acid solution takes place more readily at an axial than at an equatorial group ; similar differences occur with N-bromosuccinimide in the steroid field. This exception to the general rule that equatorial groups react the more readily was resolved by Barton's suggestion[17] that in these oxidations the rate-determining step was still an attack on an equatorial substituent, that is, on hydrogen. In other words, the rate-determining step did not involve the hindered axial hydroxyl group. This suggestion has received elegant confirmation from the studies of chromic acid oxidations by Westheimer *et al.*[18]. These studies show that the mechanism of such chromic acid oxidations does involve attack on the hydrogen atom as the rate-determining step.

It is apparent that for a given reaction with a pair of anomers the ratio of rates will be determined by two factors : (*a*) the actual reaction mechanism will determine which of the substituents is subject to the rate-determining attack ; (*b*) the overall reaction will be the more rapid when the substituent subject to the rate-determining attack is equatorial.

Turning now to the case of glucose oxidation by bromine, it is suggested that the reaction mechanism of this oxidation involves, as a rate-determining step, a direct reaction at the hydroxyl group. This seems most likely in view of the electrophilic nature of bromine. Since the hydroxyl at carbon atom 1 in β-D-glucose is equatorial, this group should therefore be more reactive in such a reaction than the corresponding (axial) hydroxyl of α-glucose.

Although in the reactions of sugars and halogens it is usually difficult to specify the precise nature of the substrate or oxidant, it has been shown that in the bromine reaction (which with β-glucose is rapid even at 0° and gives almost theoretical yields of the lactone) free bromine is the actual oxidant[8]. Isbell and Pigman suggested that the oxidation took place through an addition product between the ring oxygen atom and bromine[8]. Only in β-glucose was further reaction possible because of the favourable steric situation. Whether or not this addition occurs, it is now suggested that the electrophilic reagent (bromine) will make an initial attack on the equatorial hydroxyl group leading to the hypobromite intermediate (III). If this is the rate-determining step, the rate should be diminished by acid, in harmony with the observed facts.

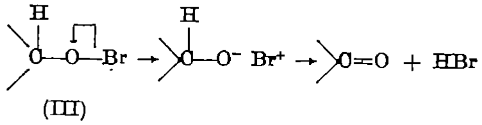


(III)

Considerable evidence substantiating a hypobromite intermediate such as (III) is found in the known reactions of the simple aliphatic hypohalites. Primary and secondary hypohalites are very unstable, particularly to light[26] ; although it has more recently been stated that, in the complete absence of traces of acid, ethyl hypochlorite is stable for several hours[27]. On spontaneous decomposition, primary hypohalites yield aldehydes, secondary hypohalites yield ketones, and the more stable tertiary hypohalites yield a ketone and an alkyl chloride according to the following equations[28] :

$$\begin{aligned} &RCH_2OCl \rightarrow RCHO + HCl \\ &R_2CHOCl \rightarrow R_2CO + HCl \\ &R_3COCl \rightarrow R_2CO + RCl \end{aligned}$$

Similar studies led to the conclusion that secondary hypohalites are the least stable[26]. Although alkyl hypobromites are less well known, methyl and ethyl hypobromites can be prepared, at least in solution[29]. It seems reasonable, therefore, to postulate (III) as an intermediate and to make the further assumption that it decomposes rapidly to form the $=CO$ group of the lactone in the same way as do the secondary hypohalites. Since oxygen is more electronegative than bromine, the reaction is written as below ; that is, as a transfer of a hydride ion to a brominium ion. Such a transfer is very similar to that proposed by Hammett for the mechanism of the Cannizzaro reaction[30].



(III)

In one case a slightly increased reactivity of α-glucose to an oxidizing agent, chlorous acid, has been observed[31]. This reaction is certainly more complicated than that with bromine, as indicated by the approximate stoichiometric relationship :

$$RCHO + 3HClO_2 \rightarrow RCOOH + HCl + 2ClO_2 + H_2O$$

Additionally, some cleavage of the carbon chain occurs with formation of oxalic acid. Owing to unfavourable experimental conditions, it was not possible to prove or disprove whether δ-gluconolactone was an intermediate product. It is tentatively suggested that, in this chlorous acid oxidation, the molecular species involved is the free aldehyde (or aldehyde hydrate) form of glucose. Although the results of Jeanes and Isbell[31] are insufficient for precise kinetic calculations, it can be estimated that for the initial period the ratio of oxidation-rates (α : β) is about 2. This is of the same order as the observed ratio of rates of mutarotation ($k_\alpha : k_\beta = 1{\cdot}883$)[8], a process which probably does involve the free aldehyde form. The slightly more rapid oxidation of α-glucose is therefore a result of the more rapid opening of the ring which occurs with this anomer.

Marked differences of rates in favour of β-glucose occur in the oxidation with sodium hypoiodite in alkaline solution[1b] (β : α = 25). It is believed that similar considerations to those outlined above in connexion with the bromine oxidation will also apply in this case.

## Mechanism of Enzymatic Oxidation of β-Glucose

It was originally concluded by Bentley and Neuberger[5] that the initial step in the notatin reaction was removal from glucopyranose either of a proton and an electron, or alternatively a hydride ion. In the absence of definite information, these reactions were written so that the hydrogen atom removed first was that attached to carbon. If the arguments developed here are correct, it will be more likely that the initial point of attack by the enzyme is the equatorial hydroxyl group. It is suggested that this attack is developed through an electrophilic site on the enzyme surface (indicated as *X* in Fig. 3), leading to the removal of a proton and the formation of an enzyme-substrate intermediate (IV). This intermediate is analogous to that (III) postulated in the bromine oxidation. The final steps are now very much the same as those originally suggested, that is, transfer of a hydride ion from the intermediate (IV) either directly to the prosthetic group, flavin adenine dinucleotide (FAD), or possibly first to some other reactive site on the enzyme surface. The overall result is thus the transfer of the proton removed initially and the hydride ion to flavin adenine dinucleotide. Although this has been discussed in terms of an ionic mechanism, as originally pointed out[5] it could equally well be represented as a radical mechanism. The only essential difference between the mechanism now proposed and that originally suggested is that the initial point of attack is now believed to be the equatorial hydroxyl group.

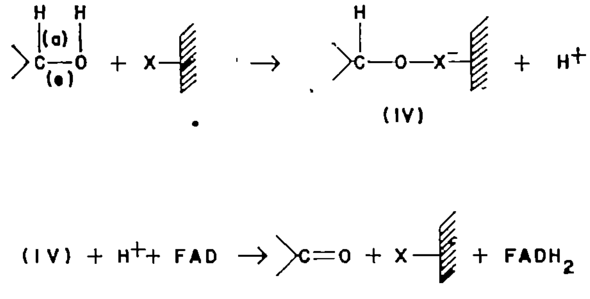


Fig. 3. Mechanism of oxidation of β-glucose with notatin. (*X* is a postulated electrophilic site on the surface of the enzyme)

The biochemical oxidation =CHOH → =CO has also been extensively studied in the inositol series, both with bacterial suspensions (*Acetobacter suboxydans*, *Aerobacter aerogenes*[31,32]) and with cell-free enzyme preparations[33]. The specific stereochemical requirements for these oxidations are that the group being oxidized must be an axial group, and that the carbon atom *meta* to this group must carry an equatorial hydroxyl. These oxidation mechanisms, therefore, are different from those operating in the case of glucose, but closely resemble the chromic acid oxidations discussed earlier; it seems most probable that they involve attack by the enzyme on the equatorial carbon–hydrogen bond as the rate-determining step. Mechanisms analogous to that proposed for the chemical oxidations[25] can readily be envisaged for these enzymatic reactions.

## Conclusion

The observed differences in the rates of oxidation of the glucose anomers are believed to be explained on the basis that: (*a*) the reaction mechanism necessitates a rate-determining attack on a hydroxyl group; and (*b*) that in α-D-glucose the axial hydroxyl is sterically hindered.

It seems likely that similar principles will be helpful in many other branches of carbohydrate chemistry and in the interpretation of some aspects of enzyme specificity. It is perhaps significant that an enzyme (mutarotase) which catalyses the interconversion of α- and β-glucose has recently been described in some notatin preparations[34] and in animal tissues[35].

### Experiments on the Complete Suppression of Stammering

We have been conducting simple physical experiments upon people severely handicapped by various forms of stammering or stuttering, and have obtained results of surprising generality. Under certain conditions of external control, these people may be induced to speak fluently at normal speeds, and with no difficulty. The experiments clearly illustrate the fact that stammering (at least of all the varied classes examined) is caused, not by motor, but by perceptual faults.

The twenty-five volunteer subjects (all adult) of this preliminary series were introduced through speech-therapy clinics and exhibited various degrees of speech difficulty. In several cases tonic spasms up to a minute in duration were observed. In all cases, speaking was interrupted by hesitations, repetitions or silent periods. Various objective measures of the degree of speech difficulty have been adopted (for example, time to read a standard text; number of speech breakdowns; sum of durations of the gaps, hesitations and repetitions in utterance). These objective measures enabled us to estimate the improvement during external control.

External control has been exercised by interfering with the complex of monitoring and control processes associated with speaking. Two methods have been employed. In the first, a very loud tone was applied through headphones to the ears of the subject, preventing his perception of the voice sounds which he produced. A frequency of about 150 cycles per second was found most effective. The subject was required to read aloud from a simple text of about 120 words; the results are illustrated by Fig. 1. In this figure, (*a*) shows the duration of repetitions, hesitations and gaps in the speech of these subjects, summed over the period of the test, before the tone is applied; (*b*) shows the same observations when the tone was applied. In both cases, the results have been presented in sequence of subjects, rearranged along the horizontal axis in order of their usual degree of speech difficulty.

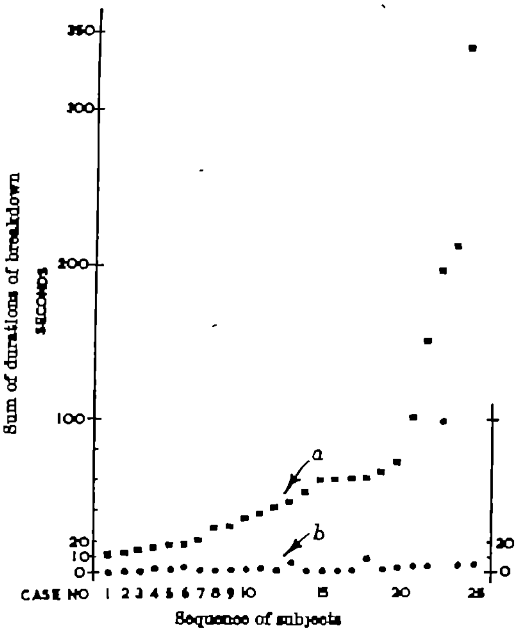

Fig. 1. Total duration of all hesitations, repetitions and silent intervals in the speech of stammerers reading a 120-word test: (*a*) usual performance; (*b*) with applied tone

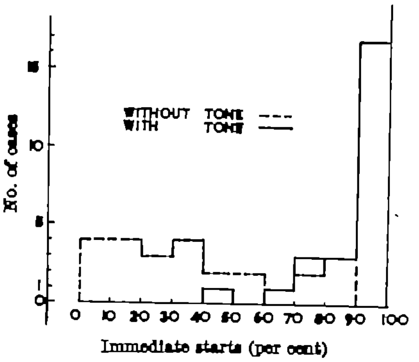

Fig. 2. Histogram showing distribution of cases according to ability to make immediate starts in utterance, both without and with applied tone

In twenty-four cases out of twenty-five, the improvement was remarkable. The exception was the only individual who normally worked in surroundings with a high ambient noise-level.

We also measured the ability of each subject to make an immediate start in utterance, each time a new starting point was indicated, by pointing to a new part of the text. Successive points were indicated randomly and in rapid sequence. We found that when the tone was applied, hesitation was markedly reduced in every case (Fig. 2).

Since aural voice-feedback for speech monitoring is mediated mainly through air and bone conduction, it seemed of interest to verify their relative influences on stammering. Blocking the air-conduction pathway only (as by stopping the ears) did not consistently alter the speech habits of stammerers; on the other hand, if both pathways were blocked (as we have shown with the above technique) stammering virtually ceases.

The second method of interference with the monitoring processes does not involve reading. The subject 'shadows' an unseen message read by the operator steadily and continuously. 'Shadowing' means repeating concurrently. In this situation, the subject did not see the text, and was obliged to concentrate on the message. It is known that such 'shadowing' presents no difficulty to people of normal speech habits[1]. It now seems that stammerers also find little difficulty and can be induced to 'shadow' fluently when reassured, even without practice.

Both normally fluent speech and stammering are believed to be habit-forming for the speaker, and on this basis the shadowing technique has been used by one of us as a form of clinical treatment for stammering. The patients were taught to copy intonation and rhythm while 'shadowing', and to work at steadily increasing speeds.

In five severe cases of stammering, this method has produced a striking improvement in a period of two to four weeks; this improvement has been maintained in all cases to date; no negative results have so far been obtained.

# The Four Possible Waves in Ionized Gas in a Magnetic Field

According to the magneto-ionic theory of Appleton[1] and others, two distinct radio waves may be propagated through ionized gas permeated by a magnetic field. More recently, three hydromagnetic waves have been found for the same medium[2,3]. A 'plasma' or electron sound wave has long been known, but only investigated for the relatively simple cases of zero magnetic field[4,5] or propagation across the magnetic field[6]. Finally, sound waves must be capable of propagation in the magneto-ionic medium. These numerous waves have been discovered from diverse approaches, and the connexion between them, if any, is not clear.

All waves in the magneto-ionic medium comprise electromagnetic fields associated with oscillations of the electrons and heavy ions. They should all be disclosed by solving the field equations together with suitable momentum transfer equations. The resulting dispersion equation for fully ionized gas is found to be of the fourth degree, indicating four, and only four, possible waves. In more complex gas mixtures other modes appear, but these may be regarded as oscillations of the ion gas within the neutral gas, together with forced oscillations of the latter. Other additional waves which seem to exist when drift motions are present[7] are not real[8], but may result from motion of the observer relative to any irregularities fixed in the gas. Since only four different wave types occur, some of the waves mentioned above must be identical.

At 'low' frequencies (where heavy-ion motion is important) the 'ordinary' and 'extraordinary' hydromagnetic waves have been found and discussed[9]. Their magnetic and electric vectors are elliptically polarized, tending to circular and plane for propagation along or perpendicular to the steady magnetic field. As the frequency rises, these waves retain their identity, although the refractive index of the medium is not necessarily always a real quantity. At 'high' frequencies (when heavy-ion motion is unimportant) they have, as simple limiting cases, the radio ordinary and extraordinary waves of Appleton's theory.

A third wave may occur at low frequencies which we call the 'magnetic-sound' wave. It is almost plane polarized, with the gas velocity vector lying between the wave normal and the magnetic field. A limiting case is a nearly pure sound wave along the magnetic field; its field is an electric potential only. As would be expected, the magnetic-sound wave is not disclosed when gas pressure is neglected (as by Åström[9]).

The fourth wave is important at high frequencies; it is analogous to the magnetic-sound wave and might be termed a 'magnetic-plasma' wave. Like the magnetic-sound wave, it has a simple limiting case in the well-known plasma waves propagated along the magnetic field[6]. The general case of the magnetic-plasma wave (like the magnetic-sound wave) is far more complicated than the special case. It has a full electromagnetic field and a Poynting flux. It does not appear in the usual magneto-ionic theory because electron gas pressure is neglected, an approximation which usually has a small effect on the ordinary and extraordinary waves but annihilates the magnetic-plasma wave.

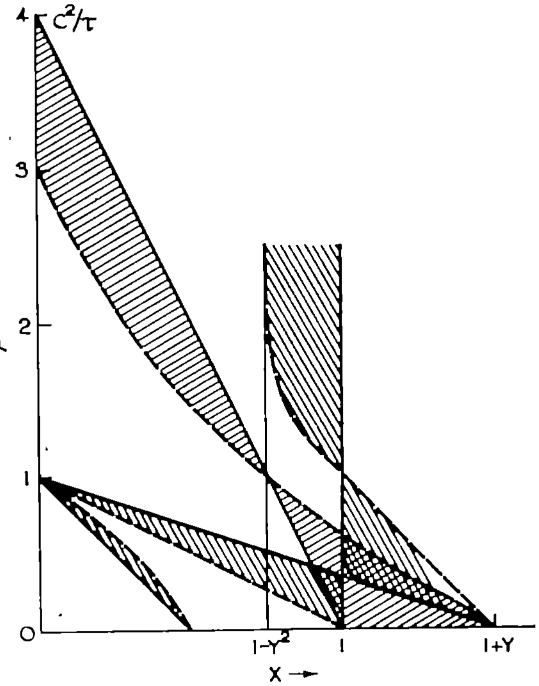

Fig. 1. Refractive indices of the ordinary, extraordinary and magnetic-plasma waves. Ordinary and extraordinary waves, ▨; magnetic plasma waves, ▩

Further study of magnetic-plasma waves is important, particularly in regard to the part they may play in the origin of intense solar radio emission. The microscopic approach used by Gross[6] leads to excessive mathematical difficulties in the general case, as well as some very surprising results in the special case he investigated. The use of transport equations may introduce some inaccuracies but permits a general survey of the wave properties to be made with relative ease. A preliminary investigation has been completed.

Vital properties of the ordinary and extraordinary radio waves were demonstrated graphically by Ratcliffe[10], whose plot is shown in Fig. 1. Here $\mu$ is the refractive index of the medium and $X$ and $Y$ the ratios of the 'plasma' frequency and gyro-frequency to the wave-frequency; $c$ is the velocity of light and $\tau$ is one-third the mean square random velocity of electrons. Full and dashed lines correspond to propagation along and across the magnetic field; the cross-hatched areas between correspond to the full range of oblique propagation. The graph allows wave velocities and reflexion points (in a variable medium) to be estimated. The corresponding plot for the magnetic-plasma wave is shown and seen to overlap that of both ordinary and extraordinary waves. Thus, under suitable conditions the ordinary (or extraordinary) and magnetic-plasma waves having the same frequency and direction of propagation have identical velocities and so will tend to travel as a composite wave.

## Anomalies in the Cosmic-Ray Shower Curves for Lead

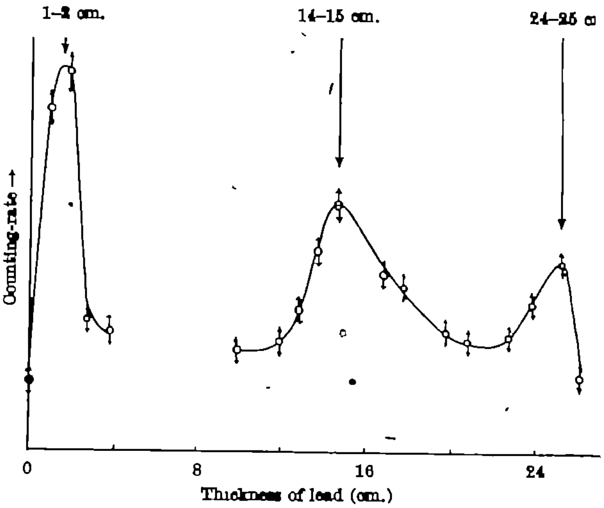
SHOWER curves have been investigated by a number of workers. The first maximum at a thickness of 1–2 cm. of lead is well established and has been satisfactorily explained. The existence of second and third maxima in the shower curve at greater thickness of lead has, however, been a matter of controversy.

Clay and Scheen[1] have found a second maximum in gold, mercury and lead; they used three-fold coincidences. Its appearance with four- and five-fold coincidences was, however, not equally well pronounced in their experiments. Clay and Klein[2] have confirmed the existence of the second maximum in tin as well, using three-fold coincidences. They, however, do not find any trace of the third maximum, as observed by Swan and Ramsey[3]. Nielsen, Morgan and Morgan[4], using four- and five-fold coincidences, give no convincing proof of the existence of the second maximum.

The second maximum has been explained by Clay and Scheen by assuming that a cosmic ray meson produces a high-energy knock-on electron in lead and the two particles account for three-fold coincidences. A four-fold coincidence will only occur if another electron is produced in the absorbing material either by a knock-on electron, by cascade processes or by the primary meson itself. They believe that this theory explains the divergent results of different workers about the second maximum.

Experiments have been carried out here using three-fold and four-fold coincidences. Our experimental arrangement is similar to that used by Clay and Scheen. The top tray consists of seven counters each 2·5 cm. in diameter and 35 cm. long placed in parallel immediately below the lead layer. The distance between the top and bottom trays was about 17 cm. The second maximum is found to occur at a thickness of 14–15 cm. of lead, and it is pronounced in all the curves obtained by an amount greater than the standard deviations. There is also a third maximum at a thickness of 24–25 cm. of lead. This occurs in all the experiments, though it is never as clear as the second maximum.

There was an indication that the second and third maxima were situated at greater thickness with four-fold than with three-fold coincidences. We have tried five-fold coincidences as well, but have not been able to detect any shift in the position of the second and third maxima obtained with the four-fold coincidences. The thickness of the lead layer was changed in steps of 1 cm. in these experiments.



The experiments were carried out under a concrete roof about one foot thick, at Lahore, lat. 31° 33′ N.

Fig. 1 gives a typical curve showing the first, second and third maxima in lead obtained by us using four-fold coincidences. We thank Mr. Taseer for drawing the figure.

## Minor Oscillations of Magnetographs

AT the Alibag Magnetic Observatory, two sets of photographic magnetographs have been in use for several years past. The magnetograph room is an insulated cubicle with double walls, double roof and double basement. A working floor or basement of flagstones is supported by trusses several feet above the ground. Isolated pillars with circular guard air-spaces come up through the insulating layers and the working floor of flagstones right from the ground. The Watson magnetographs (horizontal force, *H*; declination, *D*; and vertical force, *V*) and their recorders have rested on these isolated pillars since 1903–4. The La Cour magnetographs and their recorders are on pillars erected only above the working floor, with no rigid connexion to the ground below. The *D* instrument has been in use since 1936 and the *H* and *V* instruments have been in use since 1946.

The Watson and La Cour magnetographs for *H* and *V* have nearly the same order of magnification and are equally sensitive; but the La Cour *D* instrument is more sensitive than the Watson *D* magnetograph.

A thunderstorm passed over Alibag on June 2, 1955, between 1530 and 1900 hr. I.S.T. While the wind speed did not exceed at any time 25–30 m.p.h., the thunderclaps were very loud and persistent over

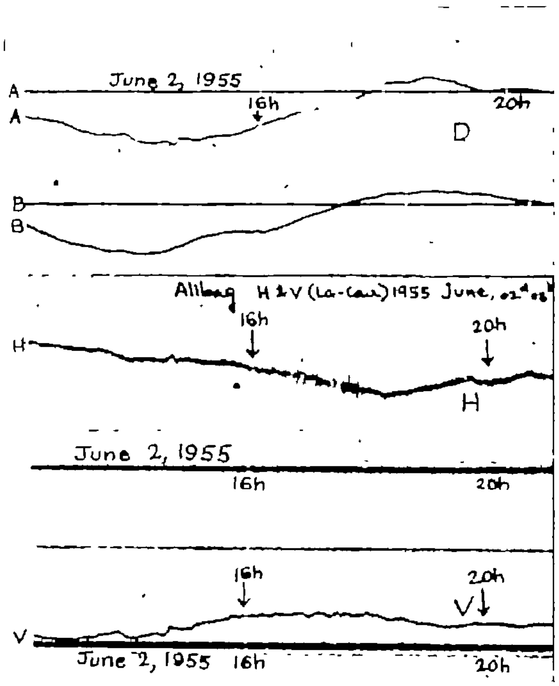

Fig. 1. La Cour magnetograms (*D*, *H* and *V*) during a thunderstorm on June 2, 1955, between 1630 hr and 1900 hr. I.S.T. *A*, June 02d. 08h. 52m. → ; *B*, June 03d. 18h. 41m. →

and near the Observatory. Between 1630 and 1800 hr. I.S.T., the La Cour *H* magnetograph shows (Fig. 1) a large number of oscillations with displacements amounting on either side to 80γ. The La Cour *D* (trace slightly fainter) also shows considerable disturbance at the same time. The *V* trace is not much affected. However, the Watson magnetographs show no disturbance. The La Cour *H* and *D* magnetographs have magnets suspended by fine quartz fibres whereas the magnet of the La Cour *V* has a knife-edge support.

It would be interesting to know if other observatories have recorded similar oscillations, and, if so, the mode of mounting their magnetographs. Ramanathan[1] has discussed the effect at Alibag of lightning discharges on a magnetometer. Records with La Cour *H* and *V* magnetographs had not commenced at that time.

We thank Mr. M. Panduranga Rao for assistance.

## Double-Illumination Microscopy

When an unstained preparation is viewed through the microscope by transmitted light (substage), light parts of it may appear black for one of two reasons: either they absorb much light or they reflect much light back towards the light-source. In the latter case, 'black' parts can be lit by incidental (suprastage) light; if the transmitted and incident lights differ in colour, then these parts will be clearly seen against a contrasting background with a marked three-dimensional effect. The reflected light is best supplied through a bullseye (or equivalent) condenser from a standard tubular lamp-house. This arrangement concentrates the reflected light beneath the microscope objective sufficiently strongly to balance the light coming through the substage condenser.

Red (magenta) and green (or blue-green) light filters appear to give the best contrast. For most purposes the transmitted light should be green, the reflected light red. If this arrangement of colours be reversed, there is a reversal of emphasis on the parts of the section presented to the eye. Thus 'normal' illumination of a ground section of bone will emphasize the corpuscle spaces and canaliculi of the Haversian systems; 'reversed' illumination will emphasize the bony matrix and its trabecular form.

This 'double-illumination' is as useful with high powers as with low, and is helpful in teaching. Full technical details will be published elsewhere [see *Irish Journal of Medical Science*, October 1955].

## Interference to the Ultra-Violet Spectrophotometry of Barbiturates

The quantitative analysis of barbiturates in body fluids is now generally carried out by ultra-violet spectrophotometry[1]. The difference in absorption at 240 mμ in 0·5 *N* ammonium hydroxide and in acid gives an accurate measure of the quantity of barbiturate.

Work so far published suggests that this is a reliable technique, as very few interfering substances have been noted. It is possible, however, that certain coumarin anticoagulants or other drugs might interfere, and readings over a wide range of frequencies are therefore taken. During the past three months in this laboratory, an interfering substance that possibly occurs naturally has been found in four livers from various cases of sudden death and in one sample of urine submitted from a drunken person who, it was suspected, might have also taken barbiturate.

The compound has been found to be soluble in ether and phenolic in character, and is therefore extracted together with the barbiturates. The method of extraction used was substantially that of Valov[2].

The similarity of its ultra-violet absorption curve with that of barbiturates in 0·5 *N* ammonia and acid (see Fig. 1) indicates that, if this substance is present, it seriously interferes with quantitative analysis of barbiturate by ultra-violet spectrophotometry. The quantities of this compound present in the liver samples have been such as to suggest barbiturate concentrations of 1–4 mgm. per 100 gm. While work is proceeding on the isolation and identification of this compound, it is felt that its presence should be reported immediately in view of the widespread use of the method. In this laboratory the ultra-violet absorption analysis of the barbiturate fraction from viscera is followed by paper chromatography in an *n*-butanol / 5 *N* ammonia solvent system[3]. In this system the unknown compound runs at $R_F$ 0·95,

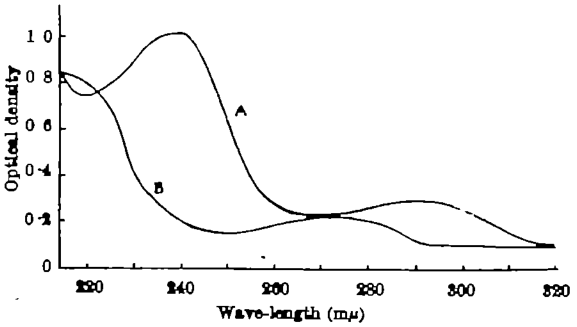

Fig. 1. Curve *A*, in 0 5 *N* ammonium hydroxide; curve *B*, in 0 1 *N* sulphuric acid

thus separating it from all the barbiturates. It also fluoresces blue in ultra-violet light. It does not react with the mercuric sulphate / diphenylcarbazone reagent[3] for barbiturates, but with ferric chloride/ ferricyanide[4] gives a blue spot.

A routine check of the ultra-violet ratio of optical densities at 265 mμ and 290 mμ, coupled with examination of the paper chromatogram under ultra-violet light, followed by elution of the fraction of $R_F$ 0·95 with $N/10$ sodium hydroxide, in which its spectrum is the same as in $0·5\,N$ ammonium hydroxide, as distinct from barbiturates, will show its presence. If this unknown compound is present, quantitative analysis of the barbiturate must be carried out by ultra-violet spectrophotometry after separation of an aliquot of the extract from the interfering substance on a paper chromatogram.

The reason for suspecting that these observations may be linked with a natural compound, possibly of seasonal origin, is not only the variety of cases in which it has been observed, but also the fact that in one case a compound having extremely similar ultra-violet absorption characteristics was isolated from the contents of a stomach. In this case the material was treated with acid ammonium sulphate[5], and the aqueous filtrate was then extracted first with ether, and, after making alkaline with ammonia, again with ether and finally with chloroform. Only in this last chloroform extract was the chromophoric group found. From the liver of this same person there was isolated from the 'phenolic' ether-soluble fraction a compound with the similar ultra-violet chromophore. This, coupled with the previous fact, suggests the substances may be metabolically related. Work is proceeding on the identification of both these compounds.

I thank Dr. F. G. Tryhorn, director of this Laboratory, for advice and for permission to publish this communication.

## Electrical Effects associated with the Mechanical Deformation of Single Crystal of Alkali Halides

IT has been reported[1] that when single crystals o natural rocksalt are plastically deformed, there is temporary increase in their ionic conductivity. Th increased conductivity appears to decay exponentiall with a time constant of the order of 1 min. The effec has also been reported[2] for synthetic crystals o potassium chloride and bromide, both pure an coloured by the presence of *F*-centres. In this cas the time constant of decay was of the order of 0·5 sec Experiments have been carried out here during th past three years to investigate this effect further using synthetic crystals of various alkali halides[3] The crystals were either grown from the melt usin the Kyropoulos technique or obtained from othe sources.

The measurements were carried out on specimen about 1 cm. × 1 cm. × 0·5 cm. in size cleaved from the crystals. The larger opposite faces were roughened with emery paper, and colloidal graphite was painted on to serve as an electrode, although other electrode materials were investigated. The specimens were placed between two parallel brass disks and a known constant stress was applied. This stress was increased in steps up to a maximum of approximately 200 kgm./cm.². The conductivity was also measured at the same time by means of a sensitive electrometer valve and d.c. amplifier. The ionic conductivity of the specimen was presented as a deflexion on the screen of a cathode-ray oscilloscope, and any change with time could be observed or photographed.

An increase in the conductivity of the following crystals (sources indicated in brackets) was observed under the influence of plastic deformation: potassium chloride (Harshaw Chemical Co., Messrs. Hilger, Ltd., and Durham); sodium iodide (Messrs. Hilger, Ltd.); and potassium iodide (Harshaw Chemical Co.). An increase of conductivity was also observed in sodium chloride from the Harshaw Chemical Co. and potassium bromide from Messrs. Hilger, Ltd., but only at high stresses (> 40 kgm./cm.²). It was notable, however, that no increase of conductivity occurred in samples of sodium chloride from Messrs. Taylor, Taylor and Hobson, Ltd., Messrs. Hilger, Ltd., Dr. Korth, Universities of Aberdeen and Durham. Where the increased conductivity was observed, it was often quite large (hundredfold) and appeared to be proportional to the stress applied. Once the increase had been obtained for any given stress and had decayed, it could only be made to reappear by exceeding the value of the stress previously reached. The time constant of decay of the increase of conductivity was in all cases in the range 0·4–1·1 sec. The experiments on the change of conductivity were carried out over a range of temperature. In general, the effect decreased rapidly with increasing temperature, and at a temperature of 400° C. it was almost negligible.

A second effect was also discovered[3], and this has also been reported independently by Fischbach and Nowick[4]. It was found with all the specimens of alkali halides mentioned above that on the application of a stress a potential appeared between the electrodes on the surface of the crystal. The sign of the potential was quite random for any given specimen, and indeed often changed in the course of an experiment, for example, with increasing stress. The potential effect was very dependent upon the state of the ystal surface and appeared to be caused by local ress inhomogeneities at the surface. Using so far possible equal stress increments, an investigation the variation of the potential effect with mperature was made. It appeared to be independent of temperature up to 180° C. but then ecreased with increasing temperature, becoming lmost negligible at 250° C. The actual value of the otential developed at the electrodes depended on e input resistance of the measuring circuit, a typical ariation being 10 V. for an input resistance of $10^{11}$ hms to 0·1 V. for $10^{8}$ ohms. The crystal thus beaved as a low-power potential source. The appearnce of a potential under stress was also a transient henomenon and it decayed with time. Generally, he time constant of decay was rather smaller than r the conductivity change, being about 0·3 sec. he potential effect was present in all the crystals entioned above but differed in magnitude from one rystal to another.

It would seem that there are two distinct effects resent when single crystals of alkali halides are echanically deformed: first, a change in the ionic onductivity which is associated with the process of omogeneous strain throughout the crystal; secondly, he appearance of a potential at the electrodes caused y stress inhomogeneities. The latter is suggested ince the potential effect depends on the nature of he crystal surface and it can appear when the value f the stress applied to the crystal as a whole is less han the yield stress for plastic flow.

It is hoped to publish a fuller account of this work lsewhere. Acknowledgments are made to the Department of Scientific and Industrial Research for a maintenance grant (T. L. G.), to the Research Fund of the Durham Colleges for a grant for apparatus, to the Physics Department, University of Aberdeen, Messrs. Hilger, Ltd., Dr. K. Korth, and Dr. J. J. Markham for gifts of crystals, and to Prof. J. E. P. Wagstaff for laboratory facilities placed at our disposal.

## Formation of Complexes of Fluorocarbons and Fluorocarbon Derivatives with Polar Hydrocarbons, Polar Polymers, Proteins and Polypeptides

VARIOUS studies started four years ago have suggested that complexes form between $—CF_3$ and $—CF_2$ groups and polar groups such as —OH, $—NH_2$, —SH, —*R*NH, etc. This interaction appears to be independent of the position of these polar groups and has been observed in solution as well as in solids. Thus, it is quite different from urea-hydrocarbon complexes[1].

In attempting to elucidate the nature of the complex, fluorocarbon acids, the corresponding salts and other fluorocarbon derivatives have been found to protect proteins against heat, various chemical denaturants such as urea, etc.; for example, it has been possible to heat a 1 per cent bovine serum albumin solution to as high as 175° C., store it at that temperature for an hour or more, and find no physical or biochemical evidence of denaturation.

Under slightly different experimental conditions, it was found that the longer-chain fluorocarbons were much more active as protein coagulants[2] than the shorter-chain corresponding derivatives. Since in the case of the carboxylate acid derivatives, for example, the acid strength is essentially independent of the chain-length, it would be necessary to postulate some effect of the fluorocarbon chain-length on the protein, probably through the hydrogen-bond network, through the polypeptide chain and/or through the polar groups on the protein surface. The protective action mentioned above is thought to involve a strengthening of the hydrogen-bond network of the protein molecule. Other evidence gathered as to the existence and nature of the complex is summarized as follows.

The curve of $\Delta n$ (change in refractive index), with $c$, concentration, in systems forming micelles, shows a change in slope when the critical micelle concentration is reached. This is observed in paraffin-chain salts[3], perfluoroacids and other fluorocarbon derivatives. When the solvent is changed from water to 1–5 per cent ethanol in water, $\Delta n$ has a maximum as a function of $c$ for perfluoroacids. Conductivity measurements (Klevens, H. B., and Vergnolle, J., unpublished results) indicate little or no interaction between the alcohol and the fluorocarbon ion. There are also discontinuities in the curves of surface tension versus concentration for solutions of fluorocarbon derivatives in mixed solvents (alcohol–water)[4]. No such discontinuity is observed in paraffin-chain salts dissolved in alcohol–water mixtures. Further, in contrast to the linear decrease in critical micelle concentration of the paraffin-chain salts with increase in alcohol concentration[5], a larger initial decrease in this concentration of perfluorocarbon acids and other derivatives is observed upon the addition of various polar hydrocarbons, followed by a region in which there is little further decrease in critical micelle concentration with increase in the concentration of polar additive[6].

These results indicate the presence of two components in solution: (1) a complex between fluorocarbon and alcohol; and (2) a non-complexed fluorocarbon.

In a study of the spectra of propanol in various solvents[7], it was observed that there is a marked hypsochromic shift when the solvent is changed from a hydrocarbon to a fluorocarbon. This blue shift is much more than is observed for compounds such as the aromatic hydrocarbons, where spectra are usually only sharpened by change of solvent from hydrocarbon to fluorocarbon.

Nuclear magnetic resonance studies (measurements made for me by G. R. Holzman, J. H. Anderson and W. Koth, of the Mellon Institute, and by J. N. Shoolery, of Varian Associates) of perfluorooctanoic acid in water, in a 1 per cent butylamine solution, and when adsorbed on bovine serum albumin molecules, show definite and marked differences in their $—CF_3$ spectra. For equivalent fluorine concentrations in the three systems studied, there was a relative decrease in the $—CF_2$ spectra and a correspondingly much greater decrease in the $—CF_3$ spectra as the solvent was changed from water to butylamine in water, and an even greater change was observed when protein was present.

These latter measurements are the first definitive ones which support the above hypothesis as to direct interaction between $-CF_2$ and $-CF_3$ and various polar groups.

Ultracentrifuge, viscosity and light-scattering measurements and partial molar volume data on these fluorocarbon–polymer systems also indicate some interaction. Details of these measurements will be published shortly.

The major portion of this work was done and various concepts and conclusions were reached, while I was an Advanced Research Scholar under the Fulbright Act in Paris, 1951–52. Further confirmatory evidence was obtained at the University of Minnesota and in the Graduate School of Public Health at the University of Pittsburgh.

# Direct Spectrophotometric Determination on Paper of Chromatographic Spots of Cobalt and Copper

QUANTITATIVE paper chromatography is likely to become a general micro-analytical method on account of its penetrating power and rapidity. Quantitative determination of spots can be speeded up by direct titration of the spots on paper, with a reproducibility of ± 3–4 per cent in the case of molybdenum and vanadium[1]. Copper, cobalt[2], nickel and chlorides have already been studied, too.

Direct photometry or densitometry in white light has been applied to the measurement of chromatographic spots of vanadium[3] revealed with oxine, of phosphorus[4], of cobalt and copper[5]. The final complex opacity includes opacity of the paper, which has to be checked millimetre by millimetre befo even chromatographic development, and has to b taken into account at the end for the piece of pape at the exact place of the spot. This is not practic when the spot travels too far away from the startin line[6].

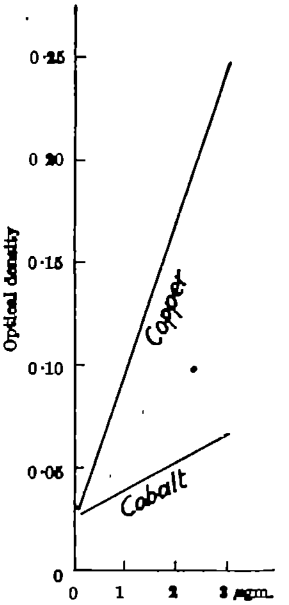

Fig. 1

Direct spectrophotometry on paper for spot revealed chromatographically has a more general an practical application. For example, a definite wave length can be used for these measurements, as whe operating on solutions. This wave-length is chose after drawing both absorption curves, that for th complex and that for the reagent; and it correspond to the spectral region where these two curves sho the greatest absorption difference.

Organic reagents and complexes are so insolubl in water that very little of them is given up to thi solvent from a strip of paper carrying a given quantit of such substances. Photometric measurements ca be carried out, however, by slipping the strip of pape bearing the spot or the vaporized reagent betwee the wall of the usual spectrophotometric cell and prismatic calibrated glass adapter, with a few drop of water to eliminate air bubbles. Optical densitie of vaporized strips with α-nitroso-β-naphthol o

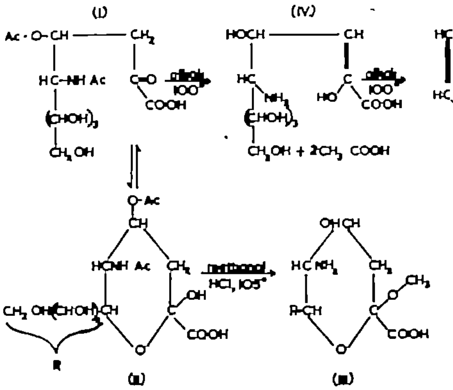
## Structural Relationship between Sialic Acid, Neuraminic Acid and 2-Carboxy-Pyrrole

AN interesting field of biochemical research was pened when Blix[1] isolated from bovine submaxillary gland mucin a crystalline reducing acid, named sialic acid[2]. Its most probable composition is given as $)_{14}H_{23}NO_{11}$ or $C_{14}H_{21}NO_{10}.H_2O$. Bovine sialic acid ontains an N-acetyl and an O-acetyl group, one rimary alcohol group and a total of five hydroxyl groups[3]. Consumption of free iodine, when sialic acid s titrated with hypoiodite, and of one molecule of ydrogen, when the acid is submitted to treatment with sodium borohydride, is interpreted by Blix *et al.*[3] as indicating the presence of a free aldehyde group. The liberation of less than one mole carbon monoxide per mole sialic acid upon treatment with sulphuric acid would suggest the presence of an α-hydroxy group[3].

Neuraminic acid in the form of its alkali-stable methoxy derivative was first isolated by Klenk from gangliosides[4] and more recently from bovine submaxillary gland mucin and from a urine mucoprotein[5], its composition being $C_{11}H_{21}NO_8$ or perhaps $C_{10}H_{19}NO_8$. This substance has no reducing power, but is ninhydrin-positive[4]. Sialic acid and the methoxy derivative of neuraminic acid are characterized by the purple colour they give on heating with Ehrlich's *p*-dimethylaminobenzaldehyde reagent even without alkali pretreatment (direct Ehrlich reaction), by the violet colour they produce on treatment with Bial's orcinol reagent and by the considerable humin formation on heating with dilute mineral acid.

A reducing, nitrogen-containing compound responding to treatment with Ehrlich's and Bial's reagents and with dilute mineral acid in exactly the same manner as do sialic and neuraminic acids was isolated in our laboratory as the product of an enzyme-substrate interaction[6,7]. The influenza virus enzyme and the receptor-destroying enzyme of *Vibrio cholerae* were found to liberate from ovomucin and from homogeneous mucoproteins (prepared from human urine and from bovine submaxillary gland mucin respectively) the above compound, which by dialysis was readily separated from the reaction mixture. Its properties suggested to Odin[8] and Klenk[9] close similarity to, if not identity with, sialic and neuraminic acid respectively. Upon treatment with mild alkali (0·1 *N* sodium carbonate, 100°, 20 min.) 2-carboxy-pyrrole was obtained from the enzymatically released product in a yield of about 0·05 per cent of the pure mucoprotein[9,10]. The same pyrrole compound was formed in a yield of 0·05 per cent from the homogeneous mucoproteins, known to contain sialic acid, by treatment with 0·63 *N* barium hydroxide for 8 hr. at 100° (ref. 10; see also Hiyama[11]).



The proposed structures for sialic acid ($I \rightleftarrows II$) and the methoxy derivative of neuraminic acid (III) would account for all relevant observations. The direct Ehrlich reaction given by I and III may be visualized as proceeding via IV to V, the benzaldehyde acting as a trapping agent for the otherwise acid-labile pyrrole derivative; the alkali stability of III arises from its acetal structure. Neuraminic acid (IV) may be regarded as an aldol type of condensation product of 2-amino-2-deoxy-hexose with pyruvic acid, the aldol type of linkage rendering recovery of the amino-sugar by acid treatment impossible[2,4,7]. The location in this condensation product of a keto, a hydroxyl and an amino-group in the <2,4,5> position provides optimal conditions for cyclization to pyrrole.

Direct evidence for the key reaction IV → V of the diagram was afforded by condensing glucosamine with pyruvic acid in alkaline medium heated for 20 min. at 100°. In this way, 0·5 gm. glucosamine hydrochloride and 5·1 gm. sodium pyruvate, dissolved in 500 ml. 0·17 *N* sodium carbonate, yielded about 1 per cent of the theoretical amount of 2-carboxy-pyrrole. This yield is of the same order of magnitude as that obtained from bovine submaxillary mucoprotein, assuming, as seems most likely[3], that its sialic acid content of 17 per cent is responsible for the production of 2-carboxy-pyrrole. 2-Carboxy-pyrrole was identified chromatographically and spectrophotometrically as described in detail elsewhere[10]; its quantity was calculated by means of the molecular extinction coefficient[10].

Strong support for the structures shown in the diagram is afforded by the finding[12] that *N*-acetyl-neuraminic acid, but not (III), is converted to (V) on treatment with alkali.

The ready conversion by alkali to (V) of (I) and of the enzymatically released product, with our recent observation that concomitant with the enzymatic release of this product the sialic acid content of the bovine mucoprotein is reduced by 64 per cent, leaves little doubt on the identity of the two compounds.

I am indebted to Dr. J. W. Cornforth, London, for advice and suggestions throughout the work.

## Occurrence of *n*-Nonadecanoic Acid in Ox Perinephric Fat

WHEN *n*-heptadecanoic (margaric) and *n*-pentadecanoic acids[1] were isolated from hydrogenated mutton fat, it was anticipated that all the normal odd-numbered fatty acids appropriate to the series would be present in natural fats. Subsequent evidence points to this being the case. Apart from the occurrence of *n*-$C_{15}$ and *n*-$C_{13}$ acids in unhydrogenated butterfat, and of *n*-$C_{15}$ and *n*-$C_{17}$ acids in unhydrogenated fish-liver oil, *n*-$C_{11}$ acid has been located in hydrogenated butterfat, and all the acids (odd and even) from $C_2$ to $C_{10}$ have been shown to be present in the volatile acids of ox perinephric fat.

We now report the isolation from hydrogenated ox perinephric fat (sample *J*/21) of trace quantities of the $C_{19}$ member, *n*-nonadecanoic acid. The chemical and physical properties of the fraction isolated (denoted *U74S3S*, weight 0·20 gm.) were as follows: saponification equivalent 297·5 (calculated for $C_{19}H_{38}O_2$, 298·5); melting point 67·5–68·0° (literature records are 68·65° [2] and 68·5° [3] for *n*-nonadecanoic acid); X-ray long spacing 43·77 A. (± 0·5 A.) for sample prepared from benzene (literature records[4] 44·13 A. for sample prepared from acetone). Were this fraction 17-methyloctadecanoic acid, its melting point would be less than 1 deg. below that of the normal isomer (literature records[5] 67·3–67·8°), but its X-ray long spacing[6] would be of the order of 36·2 A.

Although *n*-nonadecanoic acid has been prepared synthetically it has not hitherto been isolated from a natural or a hydrogenated fat.

Further details of this work will be published later.

## Volatile Fatty Acids in Phospholipids

USING the micro-technique of James and Marti it has been established that bovine muscle phosph lipids contain small amounts of volatile fatty acid and it is possible that this finding can be extend to animal phospholipids in general. Hitherto, in t absence of techniques for the micro-estimation of t low molecular-weight fatty acids, it has general been accepted that the fatty acids of phospholipi tend to be of high molecular weight only. A co secutive series of normal fatty acids from $C_2$ to $C_{10}$ h been identified in ox perinephric fat[2].

To minimize post-mortem enzymatic hydrolysis the lipids, the bovine muscle, which had been free from visible fat, was finely minced and heated i boiling ethanol within an hour of slaughter. Th ethanol-ether extracts of the dried tissue, from whic non-lipid impurities had been removed on cellulose were separated into phospholipids and glyceride A preliminary separation was carried out makin use of their differing solubilities in acetone, and fro the impure phospholipid thus obtained (phosphoru content, 3·7 per cent) further glyceride was separate by using silica gel previously activated for 24 h at 120° C. Glycerides were eluted with chloroform[4] while under the same conditions phospholipids wer adsorbed on to the silica gel. The phospholipid (phosphorus content, 3·9 per cent) were then elute with methanol. Purified solvents were used in th extraction and separation procedures. It was foun that the muscle contained 2·71 per cent glyceride and 0·57 per cent phospholipids.

The phospholipids were hydrolysed by refluxing with 1 per cent sulphuric acid in ethanol for 3 hr. and then with approximately 13 per cent potassiu hydroxide in ethanol for 5 hr. After removal of th unsaponified material by ether extraction (6·9 pe cent by weight) the fatty acids were steam-distilled. The soaps of the acids volatile in steam were concentrated to an approximately normal solution and an aliquot was acidified and applied to the gas-liquid chromatogram by the procedure suggested by James and Martin[1]. The column was operated at 137° C.

The acids identified were acetic, octanoic, propionic, hexanoic, butyric, *iso*-valeric and valeric in decreasing amounts on a molar basis. These volatile acids represented approximately 0·17 per cent by weight of the total fatty acids present in the muscle phospholipids.

## Protection of Deoxyribonuclease from Ionizing Radiation by Adsorbents

THE present communication presents experimental evidence which indicates that adsorption of deoxyribonuclease on a liquid–solid interface affords protection of enzymatic activity from radiation damage. Other means of protecting enzymes in aqueous solutions have been described by various investigators[1–6], but, to our knowledge, no information is available concerning the protective effect of adsorption.

Crystalline deoxyribonuclease (DNase crystalline, purchased from Worthington Biochemical Co., Freehold, New Jersey) with a *p*H optimum at 7·5 was used in all experiments. The enzymatic activity was determined according to Kowlessar *et al.*[7]. Although the enzyme adsorbed on cellulose powder could not be eluted, the suspension of the adsorbed enzyme showed enzymatic activity 10–35 per cent less than that noted when the enzyme was in aqueous solution. 10 ml. of a solution containing 5 μgm. of the enzyme and 5 mgm. of cellulose powder (Whatman standard grade cellulose ashless powder) was irradiated with 1,090 r. in a glass centrifuge tube while being stirred. The radiation factors were: 206 kVp., 1,453 r. per min., 20 m.amp., no filtration and target–object distance of 10·3 cm.

In all experiments, the enzymatic activity of the adsorbed and non-adsorbed deoxyribonuclease fractions, separated by centrifugation, was determined before and after exposure to X-rays. In the case of pre-exposure samples, the system was equilibrated first by stirring for 20 min. A typical experiment (2*a*, *b*) in Table 1 shows that the non-adsorbed fraction of the enzyme was almost completely inactivated, whereas the adsorbed fraction of the enzyme was protected significantly from inactivation by X-rays.

In another experiment (Table 1, 3*a*, *b*) the cellulose was separated after thorough mixing with the deoxyribonuclease solution. The resultant supernatant solution and precipitate were irradiated separately, the precipitate having been suspended in a volume of distilled water equal to that of the supernatant phase. The results of five experiments demonstrate again that the adsorbent protects the enzyme.

The degree of protection afforded the enzyme by the adsorbent is a function of the amount of enzyme in the adsorbed state. This is illustrated by the results in Table 2 relating the amount of cellulose added to the system to the degree of inactivation of deoxyribonuclease.

Varying degrees of protection of deoxyribonuclease from X-radiation are obtained with different adsorbents such as ion-exchange resins, silica gel. 'Celite' and bone ash. This suggests that the mechanism by which adsorption protects the enzyme is not specific for any one adsorbent. The biological implications of such a phenomenon are exemplified by preliminary observations which suggest that deoxyribonuclease is protected from inactivation by X-rays when adsorbed on rat spleen mitochondria.

Table 1. EFFECT OF X-IRRADIATION ON THE DEOXYRIBONUCLEASE – CELLULOSE SYSTEM

| System | Enzyme activity (per cent remaining) Non-irradiated control | After irradiation | *R** |
|---|---|---|---|
| (1) Deoxyribonuclease | 100 | 13 | 13 |
| (2) Deoxyribonuclease + cellulose, irradiated together and then separated | 66 | 29 | 44 |
| (*a*) supernatant | 48 | 5 | 11 |
| (*b*) precipitate | 18 | 14 | 78 |
| (3) Deoxyribonuclease + cellulose, irradiated after separation into solid and liquid phase | | | |
| (*a*) supernatant | 100 | 52±7 | 52 |
| (*b*) precipitate | 100 | 84±20 | 84 |

$$* R = \frac{\text{Enzyme activity after irradiation}}{\text{Enzyme activity of non-irradiated control sample}} \times 100.$$

The enzyme activities in experiments (2), (2*a*) and (2*b*) are referred to (1) as 100, whereas in (3*a*) and (3*b*) the respective non-irradiated sample serves as reference point.

In (3*a*) and (3*b*) the standard deviations are also shown.

Table 2. RELATIONSHIP BETWEEN THE DEGREE OF THE PROTECTION AND THE AMOUNT OF THE ADSORBENT

| Amount of cellulose (mgm.) | Per cent of enzyme + activity remaining after irradiation | Per cent of activity with supernatant* |
|---|---|---|
| 0 | 39 ± 14 | 100 |
| 0 1 | 36 ± 7 | 69 |
| 1 | 35 ± 1 | 84 |
| 5 | 72 ± 13 | 49 |
| 10 | 92 ± 10 | 20 |
| 30 | 80 ± 10 | 6 |
| 100 | 100 | — |

$$* \text{Per cent of activity} = \frac{\text{Activity in the supernatant}}{\text{Total activity}} \times 100.$$

Several hypotheses may be advanced in order to explain the observed protection by adsorbents: (1) the ratio of free radicals to enzyme molecules in the adsorbed fraction is much lower than it is in the supernatant phase; (2) the free radicals do not migrate freely into the micellar space; or (3) competitive reactions on the surface of the adsorbent decrease the number of free radicals available for enzyme inactivation. Since the number of adsorbent particles involved in this system is much less than the number of molecules of the usual protective reagents, and since little protection is afforded the enzyme in the supernatant phase by the dispersed adsorbent (Table 1–2), it seems unlikely that the protective effect obtained is of the customary competitive variety[1,2,3].

These experiments and others of a similar nature will be published in detail elsewhere.

## A New Method for 'Hydrolysis' of Nucleic Acids with Phosphorus Pentoxide

NUCLEIC acids consist of nucleotides linked together by ester linkages between the phosphate group of one and the ribose group of another nucleotide as shown below:

Base—sugar—phosphate
|
Base—sugar—phosphate
|
Base—sugar—phosphate
|
Base—sugar—phosphate

Hence it should be possible to separate the bases in free form if the sugar links are broken down. Sugars are known to be susceptible to hydration.

Table 1. Phosphorus Pentoxide Hydrolysis of Deoxyribonucleic Acid isolated from Tumour Tissue

Kjeldahl nitrogen value for original deoxyribonucleic acid, 10·5 per cent. Nitrogen value calculated from the bases isolated, 9·3 per cent.

| | (I) Found (μgm. base/mgm. deoxyribonucleic acid) | (II) Calculated nitrogen value from col. I (μgm. nitrogen/mgm deoxyribonucleic acid) |
|---|---|---|
| Adenine } Thymine } | 110* | 44* |
| Guanine | 70 | 33·6 |
| Cytosine | 40 | 15·2 |
| Uracil | — | — |
| | Total nitrogen | 92·8 |

* Adenine and thymine have the same $R_F$ values for the solvent used, hence in the calculation of nitrogen values the mean value for adenine and thymine is used.

Experiments were therefore carried out with the view of breaking down the ribose bridges with a dehydrating agent such as phosphorus pentoxide in order to find if the free bases are liberated. The results form the basis of the present preliminary report of a new method of 'hydrolysing' the nucleic acids.

Nucleic acids separated from biological materials by the method of Chargaff *et al.*[1] and commercial samples of deoxyribo- and ribo-nucleic acids were used for the investigations. To 10 mgm. of dry nucleic acid powder in a clean dry test-tube, sufficient phosphorus pentoxide was added to cover the nucleic acid. The tube was stoppered, shaken vigorously and then heated in an electric oven at 150° C. for two hours. To the charred mass 2·5 ml. of 0·1 *N* hydrochloric acid was added to dissolve the bases. The solution was filtered to separate the carbon particles. The clear solution was then spotted on a Whatman No. 1 filter paper and an ascending chromatogram run overnight using 79 per cent saturated ammonium sulphate solution, 19 per cent water and 2 per cent *iso*propanol as the solvent[3]. After drying the chromatogram at room temperature, the positions of the purines and pyrimidines were located by taking a contact print with ultra-violet light[4] on Kodak rapid reflex document paper (*DOUSTAT*, 23). Corresponding areas on the chromatogram were then cut out and eluted by overnight extraction with 10 ml. of 0·1 *N* hydrochloric acid. The bases were estimated quantitatively[2], using the Beckman spectrophotometer (Model *D.U.*) at 265 mμ. The results of some analyses of tumour deoxyribonucleic acid are shown in Table 1. Here it will be seen that the Kjeldahl nitrogen value for the isolated deoxyribonucleic acid is 10·5 per cent and that accounted for by the isolated bases is 9·3 per cent, thus indicating that the hydrolysis and the recoveries are fairly complete.

The treatment with phosphorus pentoxide is a fairly drastic one, and before the usefulness of the method could be assessed it is necessary to study its effects on pure purines and pyrimidines, to rule out the possibility of destruction of the bases during the process. This has been tested by recovery experiments after treating pure samples of the base individually with phosphorus pentoxide. The result are shown in Table 2.

Table 2. Recovery of Pure Purines and Pyrimidines subjected to Treatment with Phosphorus Pentoxide and Subsequent Separation by Paper Chromatography

| | Quantity of base taken (μgm.) | Quantity of base found (μgm.) | Percentage recovery (per cent) |
|---|---|---|---|
| Adenine | 250 | 250 | 100 |
| Guanine | 250 | 235 | 94 |
| Cytosine | 250 | 245 | 98 |
| Uracil | 250 | 240 | 96 |
| Thymine | 250 | 230 | 92 |

It can be seen that the recoveries are fairly good. Besides the recovery experiments, two other criteri were employed for confirming that the phosphoru pentoxide treatment does not affect the bases namely: (1) ultra-violet absorption spectra; and (2) the $R_F$ values of the bases after treatment with phosphorus pentoxide. The absorption spectra and the $R_F$ values of the bases were unaffected by the treatment.

It appears, therefore, that the new method bring about complete hydrolysis without in any way affecting the recovery of the bases. Further work on this method is in progress.

Thanks are due to Dr. V. R. Khanolkar and Dr. A. R. Gopal-Ayengar for advice and criticism, and to Dr. T. B. Panse for facilities to use the Beckman spectrophotometer.

## Effect of Denervation on the Histochemical Appearance of Cholinesterase at the Myoneural Junction

The sensitivity of the motor end-plate to acetylcholine is known to increase after denervation. Many workers have investigated by chemical analysis the cholinesterase content of denervated muscle in an attempt to explain this increased sensitivity. The results have, however, been confusing. Marnay and Nachmansohn[1] reported that the cholinesterase content of muscle increased following nerve-section, while Couteaux and Nachmansohn[2] and Stoerk and Morpeth[3] found that it became reduced. Sawyer *et al.*[4], working on skeletal muscle of the rat, guinea pig and rabbit, reported that the concentration of cholinesterase at first became reduced after nerve section and later became increased to considerably more than its normal complement. Since the results obtained by chemical analysis include the cholinesterase present in the terminal nerve fibres[5] and also that present in muscle other than at the motor end-plate, it seemed desirable to investigate the problem using a histochemical method and to confine the study to the cholinesterase content of the motor end-plate.

Fourteen guinea pigs, seven males and seven females, aged about one year were used for the present investigation. The animals were anaesthetized with ether and the sciatic nerve was cut in mid-thigh. One animal of each sex was killed by a blow on the back of the neck at the seventh, eleventh, fifteenth, nineteenth, twenty-second, twenty-eighth and forty-fifth days following nerve section. The denervated gastrocnemius was removed from each animal, and at the same time the normal gastrocnemius was moved from the other leg to serve as a control. The specimens were fixed in 10 per cent formol saline for 6 hr., and frozen sections 50μ thick were cut and then washed in distilled water for 1½ hr. Sections om the denervated and control gastrocnemius muscles were then processed using the histochemical technique described by Koelle[6] and modified by Couteaux and Coërs[7]. To ensure adequate control, denervated and a normal control muscle section om the same animal were always incubated together r exactly the same length of time. The cholinesterase appearances were assessed by studying the concentraon and distribution of the copper sulphide precipitate at the motor end-plate.

All the control muscle sections showed that the cholinesterase at the motor end-plate is situated in the walls of gutters on the surface of the muscle fibres and is present in the form of a series of horseshoe-shaped plates as described by Couteaux and Taxi[8]. The muscles which had been denervated for seven ays showed that the concentration and distribution of cholinesterase at the motor end-plate were the same as in the controls. In the muscles which had been enervated for eleven days, the concentration of cholinesterase was slightly reduced compared with he controls, while in those which had been denervated for fifteen days the concentration of the holinesterase was still further reduced and the gutters were less well defined, the edges being irregular. After denervation for nineteen and twenty-two days, it was difficult to make out the normal outline of he motor end-plate even in muscle sections which had been incubated for sixty minutes; the cholinesterase was greatly reduced in amount and its distribution was uneven; and the horseshoe-shaped plates were no longer visible. In those muscles which had been denervated for twenty-eight days the cholinesterase could only just be recognized as a faint shadow against the pale background of the muscle fibres. No cholinesterase was found to be present in the motor end-plates of muscles denervated for forty-five days. Throughout the investigation the results in both sexes, as would be expected, were identical.

These preliminary observations show that the cholinesterase concentration at the motor end-plate of the gastrocnemius muscle of the guinea pig begins to become reduced at about the eleventh day following denervation, and this reduction progresses until at the forty-fifth day no cholinesterase can be found. This gradual reduction in the cholinesterase concentration at the motor end-plate may be partly responsible for the increased sensitivity of denervated muscle to acetylcholine.

## Sources of Platelet Factor for the Thromboplastin Generation Test

The thromboplastin generation test of Biggs and Douglas[1] is of great assistance in the diagnosis of hæmorrhagic diatheses characterized by defective thromboplastin generation. One modification, due to Bell and Alton[2], substitutes the more convenient human brain extract for the platelet suspension. Human brain is not a readily available material, and the preparation of the extract from it is laborious and time-consuming.

Platelet factor is believed to be a phospholipid. Soybean is a readily available source of phospholipids, and soybean phospholipid has been used for counteracting thrombocytopenic bleeding in X-irradiated dogs[3]. A preparation similar to that of White *et al.*[3] was prepared by their method from the commercially available soybean product, 'Lecithin Emulgo No. 4'. It is a light-tan coloured powder, rapidly darkening and becoming sticky on exposure to air at 20° C. The yield is more than 50 per cent of the starting material. The powder is homogenized in physiological saline at a concentration of about 10 mgm./ml. to make the stock solution for the thromboplastin generation test. It is stored at − 20° C. It is diluted before use to from 1 : 50 to 1 : 200 with physiological saline to obtain clotting times with normal bloods of 10 ± 1 sec. Both in Cambridge and the United States (personal communication, W. N. Bell), the soybean suspension has been substituted for platelet suspension in the thromboplastin generation test and has proved satisfactory in the diagnosis of hæmophilia and Christmas disease (Fig. 1). It is intended to use it in further studies on abnormal bloods as these become available in Cambridge.

Preliminary experiments have suggested that the Bell brain extract and the soybean phosphatide are

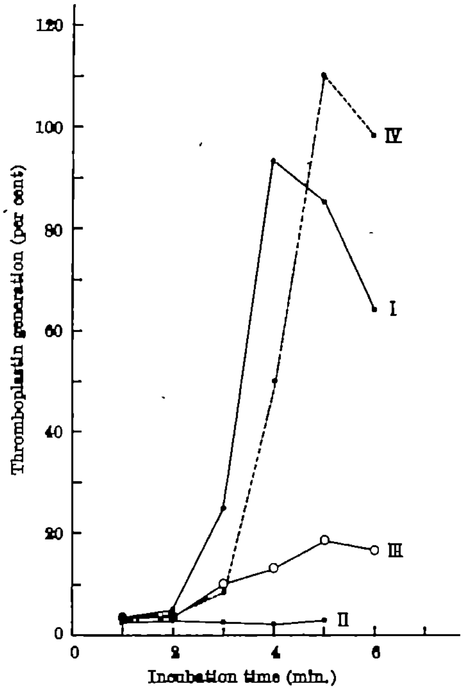

Fig. 1. Abnormal bloods in the thromboplastin generation test using soy phospholipid in place of platelet suspension. I, Normal plasma and serum; II, hæmophilic plasma and normal serum; III, Christmas disease plasma and serum; IV, Christmas disease plasma and normal serum

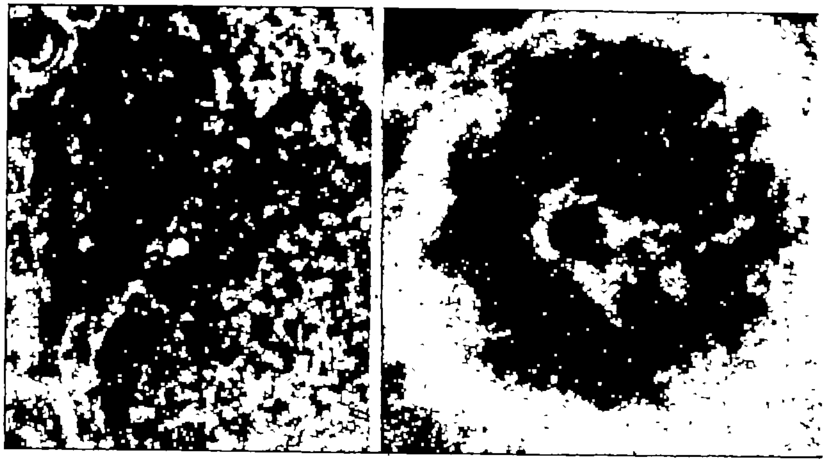

[Golgi bodies of: (1) *Schistocerca gregaria*, × 750; (2) *Laccotrephes rubra*, × 1,600

similar in nature. Further proof has been obtained by chromatographing the two materials on Whatman No. 3 paper impregnated with silicic acid. The papers were developed with 30 per cent methanolic chloroform by the ascending method, dried, sprayed with 0·2 per cent butanolic ninhydrin, heated at 120° for 7 min., and, after noting the position of the positive spots, treated with phosphomolybdic acid and stannous chloride. The extracts both contain a small amount of ninhydrin-positive material of $R_F$ c. 0·0 together with a large amount of choline-containing material of $R_F$ 0·90–1·00. A small amount of choline material stays at the starting point. Further work in progress is directed towards the identification of the active material. It is to be noted that it is very difficult to obtain papers with a uniform degree of impregnation with silicic acid. It is therefore necessary to compare compounds directly on the same paper.

Work with the thromboplastin generation test for a period of two years has confirmed its usefulness as a diagnostic test; but as a method of assay for phospholipid material it suffers from the defects of most biological tests—the degree of accuracy is never better than ± 20 per cent—together with a pronounced personal error in finding the exact moment of clotting. At the faster end of the scale a difference of one second causes considerable error. It has also been suggested elsewhere[4] that the degree of division of phospholipid material in suspension partially determines its biological activity. The effect of suspension-size has not yet been determined in this laboratory.

## Golgi Bodies in Nerve Cells of Insects

Some time after the publication of Shafiq's papers[1] on the nerve cells of the locust, Prof. Vishwa Nath asked me to undertake a comprehensive study of the Golgi material in the nerve cells of invertebrates and vertebrates. I have just completed my investigations on the thoracic neurones of the locust, *Schistocerca gregaria* Forsk., and the local water-bug, *Laccotrephes rubra*. My observations are based on the study of neurones of the fifth instar and immature adults of locust and adult water-bugs.

*Schistocerca gregaria* Forsk. The Golgi bodies (lipochondria of Shafiq) of the living neurones of this locust, when examined under the phase-contras microscope, show a highly refractile dark cortex an an almost colourless medulla. Besides, there ar smaller, highly refractile, homogeneous Golgi sphere The Golgi bodies can be stained with the vital dye neutral red and methylene blue; but it is the medull of the Golgi body which alone takes up the dye From this it is concluded, in conformity with Shafiq and Roque[2], that the medulla of the Golgi body i a vacuole with acidic contents (Fig. 1).

In paraffin sections of Helly's fixed – post-chrome material and stained with sudan black, the Golg spheres present a thick outer blue-black cortex an an inner very lightly staining medulla. There ar also smaller homogeneously stained Golgi spheres In smears fixed with Flemming without acetic aci and stained with sudan black, the Golgi bodies show a homogeneous structure; but very rarely an incomplete investing rim is seen around a lightly staining medulla. In Helly's post-chromed-hæmatoxylin preparations the Golgi bodies appear exactly as in Helly's post-chromed fixation followed by sudan black. Hæmatoxylin stains the Golgi bodies as dark homogeneous spheres when preceded by chrome-osmium fixatives. They can be stained with acid fuchsin (Masson's triple stain).

In Kolatchev preparations the Golgi bodies appear as heterogeneous spheres showing an osmiophilic cortex and an osmiophobic medulla; but the osmiophobic substance becomes greatly swollen up and the spheres become flattened. A few Golgi crescents are also seen as optical sections of the Golgi spheres (Nath[3], Shafiq[1], Roque[2]). In Aoyama preparations also the Golgi spheres, showing a duplex structure, come up beautifully in finished sections; but invariably artefacts, in the form of black granules on or around the Golgi spheres, appear.

Regaud's post-chromed-hæmatoxylin preparations generally show duplex Golgi bodies; but these preparations also show neurofibrillae as described by Beams and King[4]. The Golgi bodies are completely washed out in Bouin's fluid.

Thus the Golgi bodies described by me appear to be identical with the lipochondria of Shafiq[1]. Similar osmiophil bodies (rings, semicircles, crescents and rods) have been described as Golgi bodies by Beams and King[4] and Beams *et al.*[5]. But Shafiq did not observe any neurofibrillæ.

*Laccotrephes rubra.* The Golgi bodies of the thoracic neurones of this water-bug are almost similar to the inary spheroids' of *Helix* (Thomas[6]). It has been served that in this material there is generally a anule or a crescent attached to a vacuole. The anule or the crescent appears as a dark, highly fractile component attached to the vacuole in the ving neurones examined under phase-contrast, hereas the vacuoles are seen as colourless bodies Fig. 2). The granular or crescent-shaped component f the Golgi body appears to be lipoidal in constituon, as it is stained by sudan black. It also reduces smium and silver. It is darkly stained by hæmtoxylin preceded by chrome–osmium fixatives. he vacuole can be stained with the vital dye, eutral red. When the vacuoles are homogeneously tained with this dye, it becomes difficult to see the poidal component. The optimum impregnations of smium or silver do not impregnate the vacuoles ; nd they are also not stained by sudan black. It is hus clear that the lipoidal cortical component of he 'binary spheroids' of Thomas[6] represents the Golgi material, and the vacuolar part of the spheroid he vacuome of Parat.

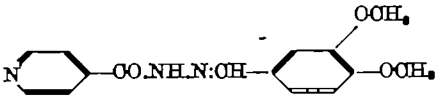
## Anti-Tuberculous Activity of Verazide (1-*iso*Nicotinoyl-2-veratrylidene Hydrazine)

THE high *in vitro* activity of 1-*iso*nicotinoyl-2-veratrylidene hydrazine (0·06 μgm. per ml.), henceforth referred to as verazide, has been previously reported by us[1] and others[2,3]. Fox and Gibas[4] report that 2 : 2-alkylidene derivatives of isoniazid (among which was included verazide) were markedly tuberculostatic in mouse tuberculosis. There is no reference, however, to the degree of activity of verazide or to its activity when given by intermittent dosage.

This report deals with the *in vivo* action of verazide and directs attention to its prolonged action and potential value in the treatment of tuberculosis. As verazide :



1-*iso*Nicotinoyl-2-veratrylidene hydrazine

is an insoluble derivative of isoniazid, it was decided to test its *in vivo* action by intermittent dosing at weekly, fortnightly and monthly intervals, using the healing ulcer technique previously described by one of us[5]. In addition, isoniazid was included for comparison. The results are shown in Table 1.

We have already shown[5] that a chemotherapeutically interesting anti-tuberculous agent is capable of scoring a healing ulcer value of 50 after 28 days treatment. Thus, verazide given in doses as low as 10 mgm./kgm. at weekly intervals exhibits a fair degree of activity, and at 30 mgm./kgm. is capable of effecting an almost complete healing of tuberculous ulcers with only three injections. At higher doses more widely spaced, for example, at 14–28-day intervals, the high degree of activity is maintained. Interestingly enough isoniazid, which is completely excreted in 24 hr. in animals[6] and man[7], is highly active (healing ulcer value 95) when 30 mgm./kgm. is given at weekly intervals. In the treatment of human tuberculosis, however, isoniazid is not given in doses exceeding 5–8 mgm./kgm. because of its toxicity.

Table 1. ANTI-TUBERCULOUS ACTIVITY OF VERAZIDE *in vivo*

| Drug | Dosage (mgm./kgm. body-weight) | Route | No. of doses | No. of animals | H.R. value* after 28 days treatment |
|---|---|---|---|---|---|
| Verazide | 5 mgm. weekly | Intramus. inject. | 4 | 4 | 15 (inactive) |
| Verazide | 10 mgm. weekly | Intramus. inject. | 4 | 4 | 58 (fair activity) |
| Verazide | 15 mgm. weekly | Intramus. inject. | 4 | 4 | 61 (fair activity) |
| Verazide | 30 mgm. weekly | Intramus. inject. | 3 | 4 | 98 (high activity) |
| Verazide | 30 mgm. weekly | *Per os* | 4 | 4 | 78 (moderate activity) |
| Verazide | 30 mgm. fortnightly | Intramus. inject. | 2 | 4 | 78 (moderate activity) |
| Verazide | 45 mgm. fortnightly | Intramus. inject. | 2 | 4 | 92 (high activity) |
| Verazide | 60 mgm. monthly | Intramus. inject. | 1 | 4 | 77 (moderate activity) |
| Isoniazid | 30 mgm. weekly | Intramus. inject. | 4 | 4 | 95 (high activity) |

* H.R. value = percentage cure of tuberculous lesions as measured by the healing ulcer technique (ref. 5).

Determination of acute toxicity by intraperitoneal injection of mice showed that the $LD_{50}$ of isoniazid was 200 mgm./kgm. body-weight, whereas the $LD_{50}$ of verazide was 700 mgm./kgm.

To summarize these results, verazide is highly active in the treatment of established tuberculosis in the guinea pig when given in intermittent doses either at 7-, 14- or 28-day intervals. It is active when given by mouth, but to a lesser degree than by injection. Finally, verazide is only one-third as toxic as isoniazid when measured by acute toxicity for mice. These findings will be reported and extended elsewhere.

We wish to thank Miss Janice Edgar and Mr. J. Buttifant for their assistance.

## Overcoming Cross-Incompatibility among some Mexican Diploid Species of *Solanum*

SPECIES of *Solanum* belonging to the section *Tuberarium* and occurring in Mexico have long been of interest to potato breeders, as several of them possess resistance to the late-blight caused by *Phytophthora infestans* de Bary. Like the tuber-bearing species of *Solanum* found in South America, the Mexican species also form a polyploid series comprising diploids ($2n = 24$), triploids ($2n = 36$), tetraploids ($2n = 48$), pentaploids ($2n = 60$) and hexaploids ($2n = 72$). These species have been classified

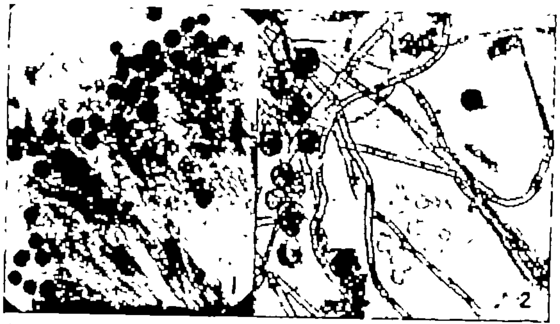

Fig. 1. Stigma and part of style of *S. pinnatisectum*, 72 hr. after pollination with *S. lanciforme* pollen. There is practically no germination of pollen

Fig. 2. Pollen of *S. bulbocastanum* germinated on an agar–sucrose–gelatin medium

in eight distinct taxonomic series, and our information concerning the cytogenetic affinities among them is still very fragmentary. As a preliminary towards gathering such data, a systematic survey of ability to cross among the diploid species occurring in Mexico was undertaken by me, during the summer of 1953, at the Inter-regional Potato Introduction Station, Sturgeon Bay, Wisconsin.

The following diploid species were used in the study: *S. pinnatisectum* (series *Pinnatisecta*), *S. bulbocastanum* (series *Bulbocastana*), *S. lanciforme* (series *Cardiophylla*) and *S. polyadenium* (series *Polyadenia*). In the first set of crosses made in the usual way (emasculation followed by controlled pollination), only the cross *S. pinnatisectum* × *S. polyadenium* succeeded. A study was then made of the causes for the failure of seed-setting in the crosses *S. pinnatisectum* × *S. bulbocastanum* and *S. pinnatisectum* × *S. lanciforme*. For this purpose, the ovaries with style and stigma were fixed in Carnoy's solution (alcohol, acetic acid, chloroform, 6 : 1 : 3), 24, 36, 48, 72 and 120 hr. after pollination, sectioned and stained with acid fuchsin and light-green. Examination of the slides revealed that in both crosses there was little or no germination of the respective pollen on the stigma even after 72 hr. from the time of pollination (Fig. 1). This duration is usually found to be sufficient to allow fertilization in compatible crosses. In the few germinated pollen grains the length of the tubes was only about three times the diameter of the pollen.

To overcome the pollen-stigma incompatibility, two techniques were tried, namely, smearing the stigmatic exudation from the pollen parent on the stigma of the pistillate parent, before pollination, and applying a suitable artificial medium for pollen germination on the cut surface of the style after removal of the stigma. An intermediate method described below led to the formation of berries and seeds in both crosses. The stigma, with a small portion of the style, was removed with a pair of fine scissors from the flowers of *S. pinnatisectum*, and a drop of an agar–sucrose–gelatin medium was applied to the decapitated surface of the style. This medium was prepared by dissolving 0·5 gm. of agar and 2·5 gm. of sucrose in 25 c.c. of distilled water to which 0·5 gm. of gelatin was added. The pollen grains of many species of *Solanum* were found to grow well in this medium (Fig. 2). After applying pollen to this medium on the cut surface of the style, the cut style was covered with a piece of moist cotton wool. From the crosses *S. pinnatisectum* × *S. lanciforme* and *S. pinnatisectum* × *S. bulbocastanum* thus made, four and three berries containing on average thirty-nine and eight seeds respectively we obtained. Seeds from these crosses were grown the Inter-regional Potato Introduction Statio Sturgeon Bay, in the summer of 1954 by Dr. R. V Hougas, who found that the plants were real hybrid

Such crosses have been attempted previously b several workers in different countries but withou success[1]. The hybrid between *S. pinnatisectum* an *S. bulbocastanum* may be of particular interest t potato breeders as a valuable breeding stock, sinc Niederhauser and Mills[2] have recently reported tha *S. bulbocastanum* is not only resistant to late bligh but is also probably the only species immune to i

This investigation was supported by a grant fro the Research Committee of the Graduate School wit funds provided by the Wisconsin Alumni Researc Foundation. I thank Drs. D. C. Cooper, G. H Rieman and R. W. Hougas for advice and help durin the course of the study.

## The Pogonophora

A report has recently been published in the daily Press alleging that Russian zoologists have lately discovered a new phylum of animals, the Pogonophora. This is, of course, a mistake, and in the paper by A. V. Ivanov, published in *Systematic Zoology*, 3, 69 (1954), and in *Dokl. Akad. Nauk S.S.S.R.*, 100, 175, 381, 595 (1955), acknowledgment is generously made to all previous workers on this interesting group. The animals have been known for some time; but Ivanov has created a new phylum for them, and this may have caused the misunderstanding.

Pogonophora are elongated tubicolous animals the body of which is composed of a short anterior portion bearing tentacles and a very long trunk. The anterior portion contains two pairs of coelomic cavities of which the first contain so-called nephridia and the second are continuous with the cavities of the tentacles. The trunk contains a third pair of coelomic cavities in which lie the gonads. The hinder part of the trunk shows repeated ring-shaped papillæ of chitinous platelets serving as adhesive organs. A dorsal nerve centre is present; but no trace has hitherto been found of gut, mouth or anus.

Although so much remains to be discovered in these animals, it is quite possible that Caullery and Ivanov are right in looking for their affinities among those groups which include the Enteropneusta. The tripartite arrangement of the cœlom and the dorsal nerve centre immediately suggest this. Details will be eagerly awaited regarding the structure of the so-called nephridium before it will be possible to compare it with the nephridium of the actinotrocha larva of *Phoronis*. Altogether, enough is known of these organisms to whet the appetite for more, and the results of Prof. Ivanov's further investigations will be awaited with interest.

# FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

## Monday, November 7

University of London (at King's College, Strand, London, W.C.2), 5.30 p.m.—Prof. Charles Sadron (Strasbourg): "The Morphology Large Chain Molecules".*

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on Lagrange's Principle as the Basis of a Unified Treatment of the Action of Electrical Indicating Instruments".

Society of Chemical Industry, London Section (joint meeting with the Institute of Metals, London Section, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Mr. N. P. Inglis: "The Production and Properties of Titanium and its Alloys".

Society of Chemical Industry, Food Group (joint meeting with the Association of Public Analysts, at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Prof. Charles Wesley Dunn (U.S.A.): "The United States Federal Food, Drug and Cosmetic Law".

Royal Geographical Society (joint meeting with the Alpine Club, at the Royal Festival Hall, London, S.E.1), at 8.30 p.m.—Mr. Charles Evans and Mr. George Band: "Kanchenjunga Climbed".

## Tuesday, November 8

British Psychological Society, Industrial Section (in Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p.m.—Dr. P. J. Fensham: "Communications and Supervisory Organisation during a Period of Automatic Innovation".

Zoological Society of London (in the Mappin Refreshment Pavilion, Mappin Terrace, Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Meeting.

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. Arthur Gaitskell: "The Gezira Scheme".

University of London (at the Royal College of Science and Technology, South Kensington, London, S.W.7), at 5.30 p.m.—Prof. A. W. Skempton: "The Development of Soil Mechanics and its Place in the University" (Inaugural Lecture).

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. O. G. Edholm: "The Effect of Cold on Man". (Fourth of fifteen Lectures on "The Scientific Basis of Medicine".)*

Illuminating Engineering Society (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. F. Jackson, Mr. R. Molloy and Mr. K. Scott: "Efficiency of Fluorescent Lamps".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. M. Hurel: "High Aspect Ratio Wings".

Institute of Metals (at the Royal Institution, Albemarle Street, London, W.1), at 8.30 p.m.—Prof. Cyril S. Smith (University of Chicago): "The Shape of Grains in Single-Phase and Two-Phase Alloys".*

## Wednesday, November 9

Institute of Metals (at the Royal Institution, Albemarle Street, London, W.1), at 10 a.m.—Symposium on "The Mechanism of Phase Transformations in Metals".

University of London (at the Postgraduate School of Medicine, Ducane Road, London, W.12), at 2 p.m.—Dr. P. Fourman: "Salt and Water Metabolism".*

Physical Society, Colour Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.30 p.m.—Mr. E. H. Leach: "Structure of the Retina and Colour Vision"; Dr. W. A. H. Rushton, F.R.S.: "The Physical Measurement of Human Cone Pigments in the Normal and the Colour Blind".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S W.1), at 5.30 p.m.—Mr. J. R. Hawkins and Mr. G. Nonhebel: "Chimneys and the Dispersal of Smoke".*

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p m.—Prof. F. H. Garner, Mr. G. H. Grigg, Prof F. Morton and Dr. W. D. Reid: "Preflame Reaction in a Diesel Engine".

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. G. B. B. Chaplin, Mr. R. E. Hayes and Mr. A. R. Owens: "A Transistor Digital Fast Multiplier with Magneto-Strictive Storage"

Society for Water Treatment and Examination (joint meeting with the Institution of Heating and Ventilating Engineers, at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1), at 5.30 p m.—Symposium on "Corrosion".

University College London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m —Prof. Sven Hörstadius (University of Uppsala): "On the Determination of the Bilateral Symmetry in the Sea-Urchin Egg".*

Society for Analytical Chemistry, Microchemistry Group (at The Feathers, Tudor Street, Strand, London, E.C 4), at 6.30 p.m.—Discussion on "The Determination of Carbon and Hydrogen".

## Thursday, November 10

Royal Society (at Burlington House, London, W.1), at 4.30 p.m.—Mr. R. A. Bagnold, F.R.S.: "The Flow of Cohesionless Grains in Fluids"; Mr. B. R. Morton, Sir Geoffrey Taylor, F.R.S., and Mr. J. S. Turner: "Turbulent Gravitational Convection from Maintained Sources".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. T. H. Kinman, Mr. G. A Carrick, Mr. R. G. Hibberd and Mr. A. J. Blundell: "Germanium and Silicon Power Rectifiers".

Society of Chemical Industry, Microbiology Group (joint meeting with the Agriculture and Pesticides Groups, at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Dr. N. F. Robertson: "Disease Resistance in Plants".

## Friday, November 11

Physical Society, Acoustics Group (in the Physics Department, Imperial College, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Dr. E. G. Richardson: "The Acoustic Interferometer".

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre, Mining Institute, Neville Hall, Newcastle-upon-Tyne), at 6.15 p.m.—Prof. L. C. Burrill: "The Optimum Diameter of Marine Propellers. A New Design Approach".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Mr. A. R. Powell, F.R.S.: "The Procurement of Some Hitherto Rare Metals".

University of London (at Wye College, Wye, near Ashford, Kent), at 8.15 p.m.—Sir Mortimer Wheeler: "The Story of the Ancient Britons".*

## Saturday, November 12

British Psychological Society (joint meeting with the Social Psychology Section, in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 2 p.m.—Mr. W. A. Belson "Learning and Attitude Changes Produced by a Television Broadcast, with Special Reference to Research Method"; Mr. Alexander Mitchell: "The Content of Communication"; Mr. P. L. Short: "The Development of Some Experimental Techniques for Obtaining Viewers' Reactions to T.V. Films"; Dr. Eunice Belbin: "The Effect of Propaganda on Recall, Recognition and Behaviour".

British Interplanetary Society (in the York Hall, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Dr. J. M. K. Kooy: "Space Travel and Future Research into the Structure of the Universe" (Overseas Lecture).

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturer or Lecturer (with teaching, research and/or industrial experience, preferably with research or industrial experience of electronic circuits) in Physics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (November 10).

Research Assistant (graduate in civil engineering) in Public Health Engineering, for work forming part of an extensive programme of research in aspects of public health engineering—The Registrar, King's College, Newcastle-upon-Tyne (November 12)

Lecturer in Pharmacology—Registrar, King's College, Strand, London, W.C.2 (November 15).

Lecturer in Fuel Technology and Chemical Engineering—The Registrar, The University, Sheffield (November 19).

Senior Research Officer (with laboratory experience in the diagnosis and investigation of diseases of equines, especially mares and new-born foals, and ability to organize a service covering diagnosis, investigation, research and advice on such diseases) at the Veterinary Research Laboratory, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (November 22).

Professor of Engineering at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Ceylon, November 24).

Director of the West African Institute of Social and Economic Research, University College, Ibadan—The Secretary, Inter-University Council for Higher Education Overseas, 1, Gordon Square, London, W.C.1 (November 30).

Lecturer (graduate, with special interest in surveying) in Civil Engineering—The Registrar, King's College, Strand, London, W.C 2 (November 30).

Lecturer in Geography—The Secretary of University Court, Glasgow (December 1).

Chair of Building Science—The Registrar, The University, Liverpool (December 10).

Lecturer in Metallurgy in the Faculty of Engineering—The Secretary and Registrar, The University, Southampton (December 15).

Chair of Bacteriology—The Secretary, The University, Edinburgh (December 31)

Assistant Experimental Officer (with training in agricultural science), for research work on the nutrition of grazing animals—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

Chemist (with first- or second-class honours degree, or equivalent qualification, and at least three years general industrial experience, preferably with a knowledge of liquid fuels and lubricants), at the Central Laboratory, Chiswick—The Recruitment and Training Officer, London Transport, 55 Broadway, London, S.W.1, quoting F/EV.550.

Lecturer (graduate of a British university, preferably with an interest in electromagnetic theory and teaching experience) in Mathematics, to teach to final B.Sc. degree standard—The Clerk, Northern Polytechnic, Holloway, London, N.7.

PRODUCE OFFICER (with a university degree in commerce, economics or agriculture and with administrative ability, preferably with experience of inspection and grading of agricultural products) with the Government of the Western Region, Nigeria—Crown Agents, 4 Millbank, London, S.W.1, quoting MIB/35384/TA.

SENIOR LECTURER (with practical experience and extensive chemical knowledge of both thermo-setting and thermo-plastic resins) IN PLASTICS TECHNOLOGY—The Clerk, National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

SENIOR SCIENTIFIC OFFICERS and SCIENTIFIC OFFICERS (with a first- or second-class honours degree in physics or electrical engineering, or equivalent qualification, preferably with experience in the field of spark and arc discharge phenomena, plasma research or particle acceleration; for senior posts at least three years postgraduate research experience is necessary), to study problems associated with the production and acceleration of charged particles—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 782/34.

## LECTURES AND COURSES

### IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

SOUTH KENSINGTON, LONDON, S.W.7

PHYSICS DEPARTMENT

(Technical Optics Section)

A Course of Practical Instruction will be given in Microscopy during the period January 30, 1956 to February 24, 1956. It will consist of eight periods of three hours each but with only two such periods per week per student. The experimental work will be arranged to suit individual requirements. As the number of students to this course will be strictly limited, early application is advisable.

Application for admission should be made to the Registrar of the Imperial College, Prince Consort Road, London, S.W.7. The fee is four guineas.

### UNIVERSITY OF LONDON

A lecture entitled "On the Determination of the Bilateral Symmetry in the Sea-urchin Egg" will be given by Professor S. Hörstadius (Uppsala) at 5.30 p.m on November 9 at University College (Physiology Theatre), Gower Street, W.C.1.

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar.

## OFFICIAL APPOINTMENTS

*The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged* 18 *to* 64 *inclusive, or a woman aged* 18 *to* 59 *inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order,* 1952.

### SOUTH AFRICAN MUSEUM

The Trustees invite applications for the post of Director of the South African Museum, Cape Town. Salary £1,400 by £50 to £1,600, plus current cost-of-living allowance (married £234) Participation in the Technical Colleges Provident Fund, administered by the Commissioner of Pensions, is compulsory. Vacation leave 38 days per annum. Duties to commence on April 1, 1956. Single fare passage provided. Candidates must hold a degree in biological sciences (preferably zoology, botany, geology) from a recognized university. If not already proficient in both languages (English and Afrikaans) the successful candidate will be expected to become so within a reasonable period. Applications, stating age, qualifications and experience to reach the undersigned on or before December 1, 1955

Further particulars may be obtained from the Director and Secretary to the Trustees, P.O. Box 61, Cape Town.

### CHELSEA POLYTECHNIC

Manresa Road, S.W.3

DEPARTMENT OF PHYSICS

Head of Department: Dr. W. H George, M Sc., Ph.D (Lond.), F.Inst.P.

Applications are invited for the post of full-time Senior Lecturer (or Lecturer) in Physics. Candidates should possess teaching, research and/or industrial experience. Research or industrial experience with electronic circuits would be an advantage. Ample time and facilities for research will be provided. The successful candidate will be graded as Senior Lecturer or Lecturer in accordance with qualifications and experience. The salary scales attaching to these grades are as follows: (a) Senior Lecturer: men, £1,065 by £25 to £1,215 per annum; women, £882 8s. by £20 to £1,215 per annum, plus London allowance of £36 or £48 according to age. (b) Lecturer: men, £965 by £25 to £1,065 per annum; women, £799 11s by £20 to £1,065 per annum, plus London allowance Placing on the scale will be in accordance with previous service in a similar capacity.

Further particulars and form of application may be obtained by sending a stamped addressed foolscap envelope to the Clerk to the Governors. Applications should be submitted within fourteen days of the appearance of this advertisement.

---

ELECTRONIC ENGINEER OR PHYSICIST required for the development of new colour television tube. Technological ability essential. Experience in vacuum tube techniques and in electronic circuitry desirable. Salary £800 to £1,200 according to qualification. Good prospects for future.—Applications to Head of the Department of Electrical Engineering, Imperial College, London, S W.7

---

### EXPEDITION TO ANTARCTICA

THE FALKLAND ISLANDS DEPENDENCIES SURVEY, which maintains isolated land bases in the Antarctic, requires a MINING GEOLOGIST. Salary £1,000 a year with all found, including clothing and canteen stores. Candidates, preferably single, must be of high physical standard and must possess a good honours degree in mining geology Field experience of not less than five years is essential. They should have a genuine interest in polar research They will be required to spend 18 or 30 months in the Antarctic under conditions which are a test of character and resource.

Write to the Crown Agents, 4 Millbank, London, S.W.1. State age, name, in block letters, full qualifications and experience, and quote M3B/35406/NF.

### DEPARTMENT OF AGRICULTURE

DUBLIN

Applications are invited for a temporary post of Biologist in the Fisheries Branch of the Department of Agriculture. Applicants must hold a recognized university degree (or equivalent qualification) for which an adequate study of zoology and botany is necessary. The salary will be at the rate of £577 inclusive a year (man) and £485 inclusive a year (woman).

Applications should be made by letter addressed to the Secretary, Department of Agriculture (Establishment Division), Upper Merrion Street, Dublin, giving full details of qualifications and experience and enclosing copies of references. Applicants with service in the Defence Forces, or Auxiliary Defence Services, should give full particulars. Latest time for the receipt of applications 5 p m. on November 15, 1955.

### UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment to a Lectureship in Anatomy. Preference will be given to applicants who have a B Sc honours or M.Sc. degree with training in comparative anatomy and histology. The substantive salary attached to the post of Lecturer is on the scale £850 by £50 to £1,150 per annum In addition a married man will receive cost of living allowance at such a rate as may be authorized from time to time, the present rate being £234 per annum. The successful applicant will be required to assume duty in Johannesburg on January 3, 1956, or as soon as possible thereafter. An allowance is made towards travelling expenses.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in South Africa and London, is November 28, 1955.

### ST. MARY'S HOSPITAL MEDICAL SCHOOL

LEVERHULME RESEARCH FELLOWSHIPS

Applications from graduates in medicine or science are invited for three Leverhulme Research Fellowships of a value of £800 to £1,000 per annum. The Fellowships will be for a period of a year, renewable up to three years, and may be held in any pre-medical, pre-clinical or clinical department of the Medical School

Applications (in duplicate), stating age, qualifications, experience, and a brief outline of the research work proposed, together with the names of two referees, should reach the Secretary, St Mary's Hospital Medical School, Paddington, W 2, not later than November 26

---

DEPARTMENT OF AGRICULTURE FOR Scotland requires Scientific Officer (Botanist) at Plant Registration Station, East Craigs, Corstorphine, Edinburgh. Salary scale: £501 to £905 (men); £501 to £805 (women), subject to equal pay scheme. Post unestablished. Prospects of establishment for candidates between age 21 and 28. Qualifications: first- or second-class honours degree in botany. Duties: Registration of new varieties of potatoes; yield trials; development of virus-tested stocks; description of varieties and investigation of problems.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G 354/5A. Closing date November 19, 1955

---

### ROYAL TECHNICAL COLLEGE EAST AFRICA

Incorporating the Gandhi Memorial Acad
(Principal: Major-General C. Bullard, C
C.B E, B Eng, M.I.Mech.E., M.I.E E.)

Applications are invited for the following pointments in the Department of Engineer Senior Lecturer in Civil Engineering. S Lecturer in Mechanical Engineering. Candi must be capable of teaching to degree or professional level and assisting with develop of laboratories. Qualifications: degree, mem ship of I.C.E./I.Mech.E., industrial and te ing experience. Applied thermodynamics mechanics of fluids to degree level required mechanical post. Lecturers or Assistant Lectu in Civil, Mechanical and Electrical Engineer Qualifications: degree and/or membership appropriate Institution; teaching and indus experience desirable, mathematical specialist required. The College, established under autonomous Governing Council by the R Technical College of E. Africa Act, 1954, is b built in Nairobi as the main instrument in Bri E. Africa of higher technical and commer education for all races and will admit students in March, 1956. Salary scale (inclu temporary c.o.l.a.): Senior Lecturers, £1,531 £1,934 per annum; Lecturers, £1,162 to £1, per annum; Assistant Lecturers, £937 to £1, per annum, or slightly lower for transferred wishing to retain Colonial Government pen rights. (Staff on scales quoted could contrib to College pension scheme or maintain exis rights under, e.g., F.S.S U. or Ministry of Edu tion, College paying employer's contributio Status and commencing salary dependent on perience and qualifications. Partly furnis houses or flats provided, rent according to sal Free first class passes to and from Kenya first appointment, leave and normal retirem for persons appointed and wives; up to equival of one adult passage for dependent child under 21. Leave on full salary at rate of f days for each month's resident service. Tours service 24-36 months.

Further information may be obtained fr Secretary, Advisory Committee on Color Colleges, 1 Gordon Square, London, W.C.1, whom applications (five copies), giving det of education, qualifications and experien should be sent by November 28, 1955.

### UNIVERSITY OF ABERDEEN

Applications invited for two Lectureships Physiology: (1) Either on scale (c), salary £1, to £2,050 if the Lecturer has a medical qualifi tion, otherwise £1,350 to £1,550, or on scale ( salary £1,200 to £1,700 if the Lecturer has medical qualification, otherwise £950 to £1,3 The Lecturer will be required to develop the b physical aspect of physiology, and should ha research interests in muscle physiology, neu physiology or the physiology of the special sens (2) Either on scale (b), salary £1,200 to £1,700 the Lecturer has a medical qualification, oth wise £950 to £1,350, or on scale (a), salary £7 to £1,075 if the Lecturer has a medical qualifi tion, otherwise £650 to £950 Superannuati (F.S.S.U.) and children's allowance. Part removal expenses refunded.

Conditions of appointment and forms of app cation should be obtained from the Secretar The University, Aberdeen, with whom applic tions (eight copies), giving the names of thr referees, should be lodged not later than Nove ber 18, 1955. Applicants outside the Brit Isles may submit one copy only.

### COLLEGE OF TECHNOLOGY

BIRMINGHAM

DEPARTMENT OF PHARMACY AND BIOLOGY

Applications are invited for the post of Assi tant Grade "B" in biological subjects. Ap plicants should possess a good degree in one the biological subjects. Salary will be in a cordance with the Burnham (Further Educatio Scale for Grade "B" Assistants, (men) £525 b £25 (final increment £20) to £820, (women) £4 by £20 to £655 (plus equal pay increment), wi additional graduate and training allowances whe applicable. In fixing the commencing salar account will be taken of teaching and industri experience

Further particulars and form of applicatio may be obtained from the Registrar, College o Technology, Suffolk Street, Birmingham, 1, o receipt of stamped, addressed foolscap envelop Completed forms should be returned to him no later than two weeks after the appearance of th advertisement.

K R PILLING,
Clerk to the Governing Body

# ATMOSPHERIC POLLUTION IN BRITAIN

THE Clean Air Bill that the Government pro- duced at the end of July to implement the ncipal recommendations of the Beaver Report, ich called for legislation, has just received a ond reading in the House of Commons. It is no sense a party measure, and while it conforms sely to the sense and purpose of the Beaver Report, e recommendations of which have won general ceptance, in its present form it may well be regarded a working draft. As such it has not only been dely discussed in the technical Press, but also at e annual conferences of the National Smoke Abateent Society during September 28–30 and of the nitary Inspectors' Association on September 30. oreover, while the Bill itself says nothing about lphur compounds, that aspect was emphasized in pers presented, for example, at the symposium on e prevention of atmospheric and water pollution in e chemical industry arranged by the London ction of the Society of Chemical Industry last pril and in Dr. A. Parker's Des Voeux Memorial cture at the National Smoke Abatement Society's nference on September 30.

In general, the Bill has been welcomed as likely to a long way towards implementing the views of the eaver Committee. Criticism has chiefly been that ere are too many escape clauses, and a resolution lopted at the Sanitary Inspectors' Association Conrence which welcomed and pledged support to the ill urged that the reservations or exemptions conmplated in respect of offences should not be allowed obstruct its aims. It was also suggested that the sponsibility for the control of smoke from the dustrial processes scheduled in Section 109 of the ublic Health Act 1936 should remain with the local thorities, and that it should no longer be necessary serve notices for smoke nuisance.

Commenting on the Bill at this Conference, Sir ugh Beaver regretted that the Bill omitted to tablish a Clean Air Council or to declare specifically at clean air was to be the national policy. Such a claration would force nationalized industries to ke due account of this matter; and the Clean Air ouncil would be invaluable in securing co-operation research, which is difficult to achieve without some ntralized body. The Beaver Report itself lists a umber of topics on which further research or evelopment work is required, including particularly e possibilities of reducing the amount of sulphur fuel, of preventing release of the sulphur in the el into chimney gases, of removing sulphur from e chimney gas before discharge into the air and of roviding more information on the dispersion of lphur compounds in flue gases after discharge from imneys of different heights and in all atmospheric nditions.

Matters such as these, and the study of the physiogical effects of air pollution in general on health in lation to respiratory diseases and particularly the fects of combinations of sulphur dioxide and smoke, clearly call for co-ordinated effort by a number of research bodies and institutions; one outcome of debate on the Bill in Parliament should be the provision of some satisfactory means of ensuring that concerted long-range research in such matters, and in others upon which the ultimate achievement of a clean air policy in Britain depends, is neither neglected nor starved of adequate resources. This is perhaps one aspect to which scientists might give particular attention. If the proposal for a Clean Air Council is rejected, Parliament should be left in no doubt where the responsibility for effective research in this field rests. If it is suggested that it should be left generally to the Lord President of the Council or the Advisory Council for Scientific Policy, the occasion should be used for a closer scrutiny of the proposed organization, to satisfy Parliament and responsible professional opinion that the organization is adequate and appropriately staffed and provided with funds on a scale and in a way sufficient to ensure continuity of effort. The importance of such co-ordination is further indicated by the announcement on October 7 by the Public Health Committee of the Western European Union that a preliminary study of air pollution is to be made in the seven countries of the Union (Belgium, France, Luxembourg, The Netherlands, the Federal German Republic, Italy and the United Kingdom).

The question of staff may be more formidable than appears to have been recognized in the discussions that have so far taken place. In the absence of a body specifically responsible for research on the many aspects of atmospheric pollution and its prevention, it may be difficult not merely to secure a reasonable balance of effort between those varied aspects and between the short-term and the long-term effort, but still more to ensure that such research effort is not deflected, particularly in the existing shortage of scientific and technical man-power, by the exigencies of other fields of research. Moreover, it is premature to expect local authorities to carry out their greater responsibilities which the Bill proposes to place upon them unless they have at their disposal a much larger and well-trained staff.

Sir Hugh Beaver emphasized this aspect at the Sanitary Inspectors' Association's Conference at Scarborough. He does not think that the magnitude of the task is as yet realized. Pointing out that there are 200,000 furnace chimneys to be watched in the 'black areas', as well as 20,000 steam engines, he emphasized that the sanitary inspector's burden would be greatly increased; in view of the shortage of man-power, he suggested the formation of an inspecting staff below the specialist grades, which would be competent to carry out 90 per cent of the routine work. Moreover, on the other side, the prevention of smoke itself requires the use of better trained staff, and in a discussion at the conference of the National Smoke Abatement Society there was agreement that all stokers of hand-fired furnaces should be trained and certificated. Mr. Gerald Nabarro, who withdrew his private member's bill on air pollution in favour of the Government's measure, stated that last year only 650 out of 75,000 boilermen employed in industry had been trained to a minimum standard; but he agreed with Mr. Alfred Robens that in two or three years it would be reasonable to insist that only a trained stoker should be in charge of a hand-fired furnace.

It is desirable that the escape clauses of the present Bill should be considered in the light of the demands which the Bill makes for trained staff and the problem of recruiting and training appropriate staff by industry and by the local authorities. There is much force in Mr. Nabarro's criticism that there are too many escape routes for the recalcitrant owner of an industrial chimney, and the three or five years limit suggested by Mr. Nabarro for the reduction of black smoke seems much more reasonable than the seven years proposed in the Bill as it stands. On the other hand, while there may be too many loopholes, there are clauses which promise to prove a nuisance to industry to no useful purpose. The requirement under clause 6 in regard to the measurement of grit and dust from furnaces burning ten tons an hour or more of solid fuel could well be unnecessarily burdensome and so unevenly applied by local authorities as to yield no useful result.

The Beaver Committee recommended that financial assistance should be provided by local authorities and by the Exchequer towards the costs incurred by house owners in converting appliances in smokeless zones and smoke-control areas. The provision in the Bill that the Government should pay 40 per cent, and the local authority at least half of the balance, of the cost of converting domestic grates in smoke-control areas is a reasonable distribution, and is also designed to stimulate local authorities to find out exactly what a smoke-control order will entail before they determine its scope and character. Sir Hugh Beaver, however, suggested at Scarborough that financial assistance to industry is also necessary, and that it could be combined with the elimination of some of the dubious escape clauses.

It will be noted that the Bill makes no distinction between smokeless zones, in which the emission of smoke from chimneys would be entirely prohibited, and smoke-control areas in which the use of bituminous coal for domestic purposes would be restricted. The Beaver Committee proposed the use of the latter term for areas in which the domestic consumption of coal containing more than 20 per cent of volatile matter would be prohibited. If there are valid reasons for regarding it as undesirable or impracticable to make this distinction, on psychological grounds it would be preferable to retain the term 'smokeless zone' rather than to introduce the new term.

In the first place, there is the well-attested success which has attended the introduction of such zones in Manchester and elsewhere. This has depended on the understanding and support of the public, and introduction of a new term could lead to confusion or misunderstanding to no fruitful purpose. More than this: if it is important that care should be tak not to move too far ahead of the financial and tec nical resources as well as of the man-power which campaign for clear air involves, it is still mo important not to move too far in advance of pub opinion. The Clean Air Bill is best regarded as o step in a concerted campaign throughout Britain be carried out on many fronts, the success of whi will depend above all not on legislation but on t understanding and co-operation of the public. T debates on the Bill will doubtless make clear the pa which local authorities, the nationalized fuel indu tries, the Department of Scientific and Industri Research, the Medical Research Council and oth research bodies or professional institutes, the Briti Standards Institution, business firms and the Gover ment itself will play, by voluntary action as well under the provisions of the Bill. Some of tho responsibilities appear to require further delineation

While there is need for further thought an clarification in this respect, the over-riding need for a sustained campaign of public education. Th is particularly important in regard to domest smoke; the desirability of flexibility in this fiel must not be permitted to encourage laxity. Whi it can be assumed that public opinion is now firml in favour of preventing atmospheric pollution, cannot safely be assumed that all individuals are ye prepared to accept all that is involved in preventin pollution, even from their own chimneys. Th practice of 'firing' a domestic chimney instead having it swept is still too common for that assump tion to be sound. Moreover, while most are probabl now willing to accept that personal responsibility provided they know it will be effective because th same obligation rests on all, their co-operation is a once endangered if they see others taking advantag of loopholes or defying the law with impunity.

One matter which calls for further examinatio here is the availability of supplies of smokeless fue particularly for the domestic consumer. The Beave Report has been criticized as unduly optimistic o this point, though it believes that the rate of progres will be set by administration limits and the replace ment of appliances for the next five years. It i important, however, that administrative action i the creation of smokeless zones should not mov ahead of the availability of supplies of smokeles fuels, as well as of technical staff and appliances Otherwise public co-operation will be hindered an frustration engendered—if indeed friction and dis appointment do not smother the existing good wil

It is impossible to overstress the importance c securing full public co-operation and understanding and the provisions of the Bill should be carefull scrutinized in Parliament from that point of view It bears, moreover, on a further point. The Bill doe not anticipate that the cost to the Exchequer of th recommended measures will exceed some thre million pounds per annum, or that the cost of th additional technical staff to be appointed by th Ministry of Housing and Local Government and th Department of Health for Scotland will be mor than some £40,000 per annum. No estimate is give the cost to the local authorities, and here particularly the support of public opinion is essential if e necessary expenditure is to be incurred. It annot yet be taken for granted that all local uthorities in Britain are concerned to prevent noke.

What stands out above all, however, is the trifling xpenditure required locally and nationally to secure or Britain so great a benefit to the national health s well as to industrial efficiency. The Beaver Report stimated that atmospheric pollution is costing the ountry as much as £250 million a year in direct osts and loss of efficiency. This is equivalent to £10 er head of population in the 'black areas' and £5 per ead throughout Great Britain, and it excludes a loss stimated at between £25 and £50 million a year hrough the imperfect combustion of coal which itself auses much of the pollution. Dr. Parker, in his Des Voeux Lecture, also stressed this material and conomic aspect; and apart from the implications or human health and happiness, when it is realized hat for a town of 50,000 inhabitants air pollution osts about half a million pounds annually, it is mpossible to dispute Sir Ernest Smith's contention t the National Smoke Abatement Society's Conference that reasonable expenditure of even £20,000 year on proper publicity and education to further ts prevention by securing public support for the ncreased expenditure required would be amply epaid. Nor should it be forgotten that a campaign or clean air is not only imperative as a matter of ational policy; it is also an essential element in the ational fuel policy which is long overdue, and which he prospect of nuclear power makes the more mperative.

# GUY'S HOSPITAL

## Mr. Guy's Hospital, 1726–1948

By Dr. H. C. Cameron. Pp. xiv + 520 + 36 plates. London: Longmans, Green and Co., Ltd., 1954.) 30s. net.

OF all the great London teaching hospitals, Guy's is the only one which is known by the name of ts founder, and, apart from the two ancient foundaions of St. Bartholomew's and St. Thomas's, none as a more interesting history. The story has been old on several occasions. Nearly all the accounts are hort, but in 1892 Sir Samuel Wilks and G. T. Bettany published a very sound history of the institution. The many changes which took place in the succeeding alf-century, and the complete break with the old order following the passing of the National Health Act in 1946, rendered a new history desirable. Dr. H. C. Cameron, who was an alumnus of Guy's in the arly years of the present century, and who was in harge of the Department for the Diseases of Children from 1911 until he retired in 1945, had greater opportunities than most for absorbing the spirit of he place, and in this work he has with detail and harm retold the earlier story and brought it up to late.

Thomas Guy was born in Tamworth in 1644 or 1645, and was apprenticed to a printer in Cheapside. He soon set up for himself and began to specialize in the printing of cheap Bibles. There followed complications with the Clarendon Press, Oxford, which was then run rather inefficiently; but Guy soon came to an arrangement with the Delegates, and in 1684 he and his partner Parker were formally appointed Printers to the University of Oxford. The appointment lasted only four years, but by then Guy was a highly successful man. He became a sheriff of London in 1694, and he represented Tamworth in Parliament from 1695 until 1707. During this period he had made many gifts to his native place, including a fine group of almshouses and a new town hall. When the electorate rejected him at the election in 1707, he was so annoyed that he threatened to pull down the town hall.

Guy made a very large fortune, and he increased it enormously by his dealing in South Sea stock. In three months in 1720 he made £180,000, which was slightly more than half his gross estate at his death. He had long been interested in St. Thomas's Hospital, had been made a governor in 1704, and was meticulous in the administration of his gifts to convalescents. By 1721 he had decided to found a new hospital and was then discussing the plans. Guy died in December 1724, and he did not live to see his hospital in action, for the first patients were received on January 6, 1726.

In his will, Guy left detailed instructions regarding his hospital. It was to be governed by a general court consisting of not more than sixty and not less than forty governors. The president and treasurer were to hold office for life—unless they resigned or were removed by a special court. Guy envisaged his hospital as a sort of annexe to St. Thomas's, which then stood adjacent to the present Guy's site; and, though he expressed great interest in 'incurables', it is obvious from his will that the governors could admit the same type of patient as was admitted to St. Thomas's, though he hoped that they would be able to remain longer in his hospital. Between 1728 and 1734 the average length of stay of a patient in the hospital was eighty days. By that time there were four hundred beds.

One of the two physicians first appointed to the hospital was the celebrated James Jurin, who was even more distinguished as a natural philosopher than he was as a physician. Of the early surgeons, the best known is Samuel Sharp. The early nineteenth century saw the rise to international fame of the surgeons Sir Astley Cooper and Aston Key. In 1820, Richard Bright was appointed physician, and he was soon followed by Thomas Addison and the pathologist Thomas Hodgkin. With these men Guy's reached the peak of its greatness; but the succession has been ably upheld by many other distinguished men since their time. On its foundation, the salary for a physician or surgeon was £40 a year. The apothecary got £80; but in 1738 this salary was reduced to £50. Richard Stocker became apothecary in 1793, and he and his son James held the post for eighty years. James was a veritable store-room of medical lore, of the type of observation which is not easily imparted to others. When asked to see a young girl who had been sent in as suffering from pyæmia, he shook his head and said that a patient with pyæmia never did up her hair in that manner. Stocker was virtually dean of the Medical School until Frederick Taylor was officially appointed the first dean. In its early years the hospital had wooden beds which were infested with bugs, and the official bug-catcher had the same salary as a physician or surgeon. Perhaps the most lasting and constructive contribution to the development of the hospital made by one man was that of Benjamin Harrison, jun., who from 1797 until 1848 carried out the exacting administrative role of treasurer with the greatest enthusiasm, firmness and ability.

The complicated early history of the Medical School is fully dealt with in this book. 'Pupils' seem to have been admitted to the wards about 1760, and the students of Guy's and Thomas's could attend operations in both hospitals. As a result of disagreements, new arrangements were entered into in 1769 whereby the lucrative teaching of surgery and anatomy was concentrated at St. Thomas's, while the teaching of medicine, materia medica and chemistry, which as yet did not exist, was to be carried on at Guy's. Thus arose the Medical School of the United Hospitals of the Borough. It was the custom for a teacher to nominate his successor on his retirement. Astley Cooper, a Guy's man, was appointed demonstrator of anatomy in the United Hospitals School at the age of twenty-one. The classes were, of course, held at St. Thomas's, and two years later Henry Cline, a St. Thomas's surgeon, appointed Cooper as joint-lecturer with himself. The brilliance of Astley Cooper as a surgeon, and his great popularity as a lecturer in anatomy and surgery, made the United Hospitals School renowned far and wide. All the lecturers in the School regarded the lectureships as individual to themselves and they retained the fees. When Astley Cooper was about to retire from the lectureship in anatomy in 1825, his nominee as his successor was turned down by the governors of St. Thomas's without reference to the governors of Guy's, and a St. Thomas's nominee was appointed to the post. This was the beginning of the break-up of the United Hospitals School. To make matters worse, the governors of St. Thomas's refused to hand over to Guy's the magnificent collection of anatomical and pathological specimens, personally built up by Sir Astley Cooper, which was housed in the museum at St. Thomas's. The Guy's governors took action, built a museum, dissection-room and lecture room, and Astley Cooper in his old age began to form his second great collection of specimens. The Guy's School was during 1768–1805 the only London school which had organized courses in the medical, chemical and physical branches of medicine.

This fine work could only have been written by someone with a long and intimate knowledge of the hospital. Half the book is devoted to the period 1885–1948. This period, which is practically all subsequent to that covered by the work of Wilks and Bettany, was one of increasing complexity, due to the expansion of the possibilities of medical and surgical treatment, the growth of laboratories, and of rising costs with their consequences. Dr. Cameron deals in great detail with the administrative changes during this period, with the continuous expansion of the School and the additions to its staff, and with the bequests made to the hospital, especially by Lord Nuffield. The great work carried out by Sir Cosmo Bonsor as treasurer during 1896–1910, and as president from the latter date until 1919, is fully dealt with. There can be few persons surviving who know more than Dr. Cameron about the services rendered to the hospital by Sir Cooper Perry. Perry, a classics don, was appointed assistant physician in 1887, and when Steele, the first superintendent, retired in 1893, Perry volunteered to take over his post. Perry later became principal and vice-chancellor of the University of London, and his successor as superintendent, S Herbert Eason, followed the same road. Dr. Camero discussion of the work of men like Hale-Whit Herbert French, Arthur Hurst and Arbuthnot La is very sympathetic and interesting.

This book is very well produced, lavishly illu trated, practically free from typographical erro and very inexpensive. It is a pity, therefore, that should be marred by minor errors, such as th attribution of the Bright portrait to "F. R. Fa instead of F. R. Say, and by the fact that, despi the many footnotes, the actual sources of statemen are infrequently given. It should also be said that D Cameron seldom gives a quotation, either from printed or a manuscript source, without changing th punctuation and the orthography. Examples ma be found even in the transcriptions of the documen reproduced in facsimile. On pp. 90–94 a transcrip is given of a very important document dealing wit teaching in the Medical School. Dr. Cameron sa that this document has survived; but he gives n reference. Wilks and Bettany also give this documen in full, with minor variations; they also state tha it has survived, but give no reference. What th student wants to know is where this documen and others, can be examined. Such matters coul be rectified in a new edition, and it is to be hope that Dr. Cameron will soon have the opportunity t do this, and thus to set the seal on his valuable worl

E. ASHWORTH UNDERWOOD

# INTERNATIONAL CONTROL OF NUCLEAR WEAPONS

## The Bomb

Challenge and Answer. By Prof. Alexander Haddow Bertrand Russell, Lord Beveridge and Henry Usborne Edited by Gilbert McAllister. Pp. 160. (London B. T. Batsford, Ltd., 1955.) 25s. net.

IN announcing the publication of this book at th world conference of scientists to consider th effects of nuclear weapons, organized in London earl last August by the World Association of Parlia mentarians, its editor, Mr. G. McAllister, who i secretary-general of that Association, stated that it preparation had been rushed through in three month to enable publication to coincide with the Londo conference. There is little, if any, indication o hurried writing in the five essays constituting th book, though there is some padding that on reflexio might have been omitted. Mr. McAllister himsel contributes a brief introduction and an essay detailin previous proposals for world government including for example, those of Clarence Streit, Lionel Curti and others; but neither in his reference to the pas nor to the present does he justify his title, "Practica Steps for a World Authority". The longest of th other four essays is that by Prof. A. Haddow o "The Problem before Mankind", which is essentiall an amply documentated summary of present know ledge as to the effects and probable hazards, especiall biological, of nuclear explosions and radioactiv exposure in general; it ends with some remarks o the social responsibility of the man of science an the way in which that responsibility might b met.

The remarks lead to nothing more concrete than for example, the proposal for an international scienc

uncil which the late Lord Lindsay made nearly
n years ago in this connexion, and they offer no
sh suggestions for overcoming the practical diffi-
lties. Nor does Lord Russell's essay, "The Road
Peace", take the reader any further than the
gument of his earlier books or his broadcast appeal
the end of last year and the statement which he
d his co-signatories made public on July 9. Lord
ussell is realistic in his comments on the part which
e uncommitted nations must play in persuading
astern governments that it is futile to attempt to
cure merely an agreement not to use thermo-
uclear weapons. His essay is also useful for its
scussion of the limitations on the influence which
mocratic public opinion can exert; but he scarcely
ces the practical difficulties which the creation of
world authority would encounter. Much harder
nd more constructive thought than is manifest in
ny of these essays will be required if the technical
atement of the effects to be expected from a
ermonuclear war and its subscription, first by a
nall number of scientists of outstanding eminence,
nd then by scientists generally, followed by its
terpretation internationally into generally intel-
gible terms, are to have practical results.

Lord Beveridge's contribution, "The Conditions of
eace", restates the argument for disarmament, the
mitation of national sovereignty and establishment
f a supranational authority which characterize earlier
roposals for world federation without really gripping
he practical difficulties. He suggests that the British
overnment should draft and publish a considered
tatement of the conditions upon which Britain
ould be prepared to surrender the right to make
ar, including that of arming for war, and would
ake that surrender effective. Such a statement
ould be an advance on the nebulous renunciation
f war of the Kellogg Pact thirty years ago; but its
ormulation and approval in public debate could only
esult from the constructive thinking and facing of
ractical difficulties which for the most part these
ssays seem to burke.

Mr. Henry Usborne's essay, "The Approach to
Vorld Government", includes a similar suggestion;
ut his contribution is for the most part a rather
ambling review of earlier proposals for the inter-
ational control of nuclear weapons and of the stages
y which world federation should be achieved, and
e does not deal any more closely with the initial,
ntangible difficulties than either Lionel Curtis or
larence Streit. The claim that the book sketches
he outline of a world at peace and of those human
nd political institutions which are the essential
oundation and buttress of such a world can scarcely
e conceded without reservation. It presents a
hallenge and reveals how far in human understanding
ve have yet to go, but is far from providing an
nswer to the challenge. Its value is rather as a
eminder of how much thought has already been
iven during the past thirty years to the problem of
vorld government, and as a stimulus to the keener
hinking that is still required to bring such schemes
o fruition. Some of these earlier and more detailed
chemes, to which the book directs attention, may
vell merit re-examination in the changed conditions
f to-day. Nor should it be forgotten that the
nternational Conference on the Peaceful Uses of
tomic Energy, which met at Geneva in the weeks
mmediately following publication of this book, has
lready resulted in a great relaxation of secrecy
n this field and done much to re-establish the normal pattern of communication in the scientific world. The restoration of free communication of thought and ideas, as both Lord Russell and Prof. A. Haddow do not fail to note, is a first condition for the establishment of the climate of opinion and world understanding in which international political institutions can be evolved and rooted.

R. BRIGHTMAN

# THEORY AND PRACTICE OF NEUTRON DIFFRACTION

Neutron Diffraction

By G. E. Bacon. (Monographs on the Physics and Chemistry of Materials.) Pp. ix+299. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 35s. net.

ALTHOUGH neutron diffraction was demonstrated in the United States in 1936, it is only during the past ten years, through the advent of chain-reacting atomic piles, that neutron sources of sufficient intensity have enabled the technique to become of practical importance. Since, in contrast to X-rays, neutrons are scattered by nuclei instead of the electron clouds of atoms, neutron diffraction studies provide information about structure and the solid state that is complementary to the results of X-ray diffraction investigations. This point is particularly emphasized by the author in the present book.

The chief centres of active work in the field of neutron diffraction have been in Great Britain at the Atomic Energy Research Establishment, Harwell, and in the United States at the Oak Ridge National Laboratory, Tennessee, respectively. Many pioneering investigations in the subject have been carried out by the author himself at Harwell, and this first-hand account from so experienced a practitioner is most welcome. This is indeed the first general treatment in book form, though an excellent article by the author and Prof. Kathleen Lonsdale appeared in the 1953 "Reports on Progress in Physics", published by the Physical Society.

The chapters fall naturally into two groups. The first six chapters cover physical principles, experimental methods, and the derivation of the fundamental data required for structure investigations. In the chapter on experimental techniques, we are given a good insight into many of the special problems that have to be solved: for example, those of obtaining a monochromatic beam, of choosing the optimum size of specimen, and of recording the diffracted beams.

The second part, comprising seven chapters, deals with applications and is perhaps of most interest to the general reader. There is an instructive survey of the unique way in which the technique enables light atoms such as hydrogen to be located in structures where the X-ray method fails to give a solution. The author's own contributions to the development of Fourier synthesis technique, in clarifying details of the structure of potassium dihydrogen phosphate, for example, are described. Not the least of the achievements of neutron diffraction has been in the solution of structural detail in ferromagnetic and antiferromagnetic substances, and two chapters are devoted to this fascinating subject. Short chapters are included on small-angle scattering and diffraction by liquids and gases.

Some information valuable for reference purposes is presented in tabular form. Neutron and X-ray scattering data for the elements and isotopes are compared in Table 2, while the relations between the absorption characteristics of neutrons and X-rays are listed in Table 6. An interesting table on pp. 160–161 compares the properties of X-rays and neutrons for diffraction studies.

There are very few misprints or errors in the text, and the book is well bound and of a convenient size. The subject is a rapidly advancing one, papers reporting new developments appearing regularly month by month. It is therefore valuable to have this authoritative survey of the achievements to date. It should make a wide appeal to all those interested in the furtherance of knowledge about the solid state.

H. P. Rooksby

# NEW LIGHT ON AN OLD POLYMER

## Cellulose Nitrate

The Physical Chemistry of Nitrocellulose, its Formation and Use. By Dr. Frank Douglas Miles. Pp. xiii + 422 + 4 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1955. Published for Imperial Chemical Industries, Limited.) 45s. net.

THE theoretical and experimental background necessary for the understanding of high polymers is almost contemporary; the treatise of Staudinger was only published just over twenty years ago, and the modern entropy theory of their solutions is more recent still. Yet many of these substances, including nitrocellulose, have been major industrial products for a century or more. Workers in this field have therefore long felt the need for a treatise discussing, criticizing and interpreting, from a modern point of view, the great mass of experimental data and practical experience which has been acquired.

The treatise of Dr. F. D. Miles fulfils this need. His first chapter presents the X-ray and optical data on cellulose itself, and his second discusses the reaction of cellulose with nitric acid. Chapters 3–6 discuss the properties and applications of solid nitrocellulose and its gels (celluloid, leathercloth, cordite, etc.), and, finally, the last four chapters discuss the reactions of solid nitrocellulose, its fractionation, the properties of dilute solutions and the problem of solubility. The plan of the work is logical and orderly: the only criticism that can be made is that the presentation of data on solvent absorption and gelatinization in the fourth chapter, while the dilute solutions and general solubility are kept to the end, tends to hide their essential continuity.

In detail this book succeeds very well in holding the delicate balance between the old school who regarded such solutions and gels as uninterpretable except by special 'colloid-chemical' concepts, and the modernists who might consider there was nothing left to explain; in particular, Dr. Miles makes clear the importance of specific interactions between nitrocellulose and solvent molecules, although the last chapter does not tackle the difficult problem of the thermodynamic consequences of such interactions. The literature is very well covered—the long series of papers from government research establishments in France are given their proper importance, a Dr. Miles makes public for the first time much int esting work done in the laboratories at Ardeer Imperial Chemical Industries, Ltd. It would impossible in any reasonably sized book to disc all the literature on nitrocellulose: Dr. Miles h managed to include nearly all the important pape before 1954 and at the same time to exclude t enormous volume of unsound work which, before treatise, had to be ploughed through by those n to the subject.

This book can therefore be recommended to interested in work on high polymers, as well as those who specialize on cellulose and its derivative The book is well printed, and, for what it contains, very cheap.

# FURTHER STUDIES OF LAVOISIER' CHEMICAL DISCOVERIES

## Lavoisier

Théoricien et Expérimentateur. Par Maurice Dauma (Bibliothèque de Philosophie Contemporaine, Logiq et Philosophie des Sciences.) Pp. ii + 180 + 4 plate (Paris: Presses Universitaires de France, 1955 700 francs.

LAVOISIER has been the subject of many studie but some details of his life and works are st imperfectly known. M. Maurice Daumas, who h studied correspondence, notebooks and other unpu lished manuscripts preserved by the Paris Academ of Sciences, has re-examined several aspects Lavoisier's chemical works, and the present book w be of value to all who are interested in eighteent century chemistry.

A chronological account of Lavoisier's work beari on the theory of combustion, which has been con piled from many sources, shows that importa results were often read to the Academy long befor they were printed. The controversies over oxyge and water are briefly discussed, and it is conclude that Lavoisier did not himself claim priority fo either the isolation of oxygen or the combustion o hydrogen to form water, but that he did, with justic claim priority for the correct interpretation of th experiments. Many readers will agree with M Daumas that sentiment rather than impartial inquir has led to some opinions previously expressed o these topics.

M. Daumas also examines the origins of Lavoisier' "Traité Élémentaire de Chimie" (1789), showing tha it was first planned in 1780 or 1781, before the anti phlogistic theory was complete; and he gives a interesting account of Lavoisier's apparatus, much o which still exists. The accuracy attainable by scientist is limited by the quality of his apparatus a well as by his personal skill, and it was fortunat that Lavoisier could employ such excellent instrument-makers as Mégnié and Fortin.

After discussing Lavoisier's views on the nature o matter and on chemical affinity, M. Daumas concludes that, despite his genius, he could "act an think only as a man of the eighteenth century" However, he also directs attention to Laviosier' ability to "understand what was the problem of th hour, and to pursue it to its resolution"; that is rare quality which ensures greatness in any century

W. A. Smeaton

# ISTORTION OF THE *E* LAYER OF THE IONOSPHERE BY ELECTRICAL CURRENTS FLOWING IN IT

By SIR EDWARD APPLETON, G.B.E., K.C.B., F.R.S., A. J. LYON and MRS. A. G. TURNBULL

University of Edinburgh

T has long been known that the *E* layer of the ionosphere varies, both diurnally and seasonally, a fairly regular manner, in that its maximum nization density, $N_m$, is closely dependent on the lar zenith distance, $\chi$. In the earliest study of this gion, for example, Appleton and Naismith[1] found at, for the seasonal variation of noon maximum nization in south-east England, $N_m$ varied as os $\chi)^{1/2}$. Because of its substantially regular be-aviour, we have selected the *E* layer as a subject r more detailed study, to ascertain how far its roperties conform with those of an ideal ionized ayer, as classically expounded by Chapman[2]. We ave used, for this purpose, ionospheric data obtained y radio sounding from stations now operating all ver the world.

Chapman's well-known theory of ionized layer rmation is based on two simple specified assump-ions: the earth's atmosphere is considered to be othermal, and the process by way of which electrons lisappear is taken to be that of recombination. A urther tacit assumption is that there is no movement f ionization, electrons appearing, and eventually isappearing, at the same point in space.

We began our investigation by attempting to make careful comparison of the actual diurnal variation f $N_m$ in the *E* layer with that predicted by Chap-nan's theory. It can readily be seen physically, and ndeed is an essential result of the theory, that, due to he effects of recombination, the temporal variation of onization density in a given layer lags slightly behind he corresponding variation of the rate of electron roduction. Thus the day-time maximum value of $N_m$ s expected to occur after noon; while afternoon alues of $N_m$ are expected to exceed their correspond-ng forenoon values. Two well-known theoretical nethods of finding the value of the recombination oefficient $\alpha$ are, in fact, based respectively on these wo effects. For example, Appleton[3] has shown that he time delay $\Delta t$ of the maximum of $N_m$ relative to oon is given by $(2\alpha N_m)^{-1}$; so that, if the delay is neasurable, $\alpha$ can be determined, since $N_m$ is known. The other method of determining $\alpha$ is a little more omplicated, but depends essentially on the determ-nation of $\Delta N_m$, the difference between afternoon and orenoon values, for local times equally spaced elative to noon. Using the great wealth of iono-pheric data available for the Slough station, we ave used both the $\Delta t$ and the $\Delta N_m$ methods of nding $\alpha$, from the diurnal asymmetry of the *E* layer. The results obtained are very remarkable in indicating xtremely large variations of the *apparent* values of . Our problem has therefore been that of deciding whether, in fact, $\alpha$ really does vary in such a remark-ble fashion or whether the basic theory used is nadequate. In the latter case, if there were some dditional perturbing factor operative, one might ope that, as often happens in such cases, the nagnitude and nature of the discrepancy between heory and experiment would lead to the identifica-ion and measurement of the disturbing influence. As we shall see, such a hope has been, to a considerable extent, realized.

By extending our studies of the diurnal variation of $N_m$ to a range of latitudes other than that of Slough, we soon found evidence indicating that the values of *apparent* $\alpha$ obtained by the methods used could not possibly refer to the true recombination coefficient and were in fact being influenced by a perturbing factor. For example, while stations in the higher latitudes behaved like Slough, in that $\Delta t$ and $\Delta N_m$ were both found to be positive there, stations situated in a belt centred on the equator exhibited an inverse phenomenon, in that $\Delta t$ and $\Delta N_m$ were found to be negative. Evidently, then, for stations in low latitudes, the influence of the perturbing factor is so great that it can actually reverse the sign of the diurnal asymmetry and cause afternoon values of $N_m$ to be less than the corresponding forenoon values.

We were therefore led to examine afresh the whole basis of the theory of ionized layer formation, taking into account the possible influence of a likely perturbing factor. Now Chapman's theory is based on the simple continuity equation

$$\frac{dN}{dt} = q_0 \cos\chi - \alpha N^2 \qquad (1)$$

where $N$ is the electron density, $q_0$ the rate of electron production when the sun is vertical, and $t$ the time. If, however, we wish to take account of the possibility of electron transport phenomena, (1) must be written

$$\frac{dN}{dt} = q_0 \cos\chi - \alpha N^2 - \operatorname{div}(Nv) \qquad (2)$$

where the term div $(Nv)$ expresses the electron transport-rate out of the unit volume under consideration. Now, as Martyn[4] has suggested, vertical drift of neutral ionization is a type of electron transport likely to occur in the ionosphere; and Appleton and Lyon[5] have developed the Chapman theory so as to allow for the effects of such drift under conditions applicable to the *E* layer. The theory of Appleton and Lyon is, moreover, formulated directly in terms of the value of $N_m$ for a given layer, which is the quantity with which we are directly concerned in practice. From a practical point of view we are concerned with two effects of any vertical drift which may be operative, namely, the *alterations* it provokes in both the atmospheric level of the layer maximum electron density and in the magnitude of the maximum ionization density itself. We shall refer to these two departures from normality as $\delta h(N_m)$ and $\delta N_m$, respectively. The appropriate expressions for these quantities, given by Appleton and Lyon, are as follows:

$$\delta h(N_m) = \frac{v}{2\alpha N_m} \qquad (3)$$

and

$$\frac{\delta N_m}{N_m} = \frac{-\dfrac{\partial v}{\partial h}}{2\alpha N_m} - \frac{1}{4H^2}\left(\frac{v}{2\alpha N_m}\right)^2 \qquad (4)$$

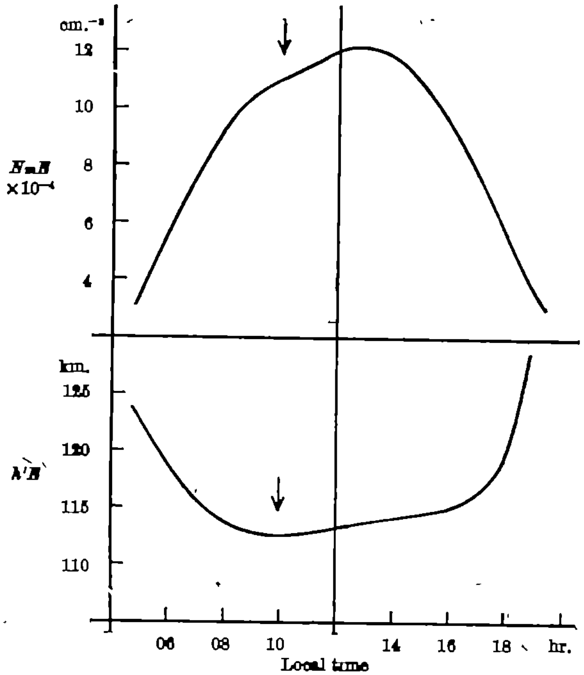

Fig. 1. Showing (upper curve) diurnal variation of Slough $E$ layer maximum ionization density, $N_m$; and (lower curve) diurnal variation of Slough $E$ layer height, $h'E$ In both cases abnormal variations (depressions) are to be noted in the forenoon when the ionospheric $S_q$ currents attain their maximum intensity

where $v$ is the velocity of vertical drift, $\frac{\partial v}{\partial h}$ is its vertical gradient (both measured positive upwards) and $H$ is the scale height of the atmospheric ionized component responsible for the $E$ layer. Equations (3) and (4) tell us, then, the corrections to the Chapman theory which are necessary to take vertical drift into account.

Now in looking for the possible intervention of vertical drift effects as a perturbing factor, we are naturally led to consider the $S_q$ overhead current system, which is responsible for the daily solar magnetic variations, as a likely origin, since there is ample evidence that this current system flows at or near the level of maximum ionization in the $E$ layer. We were additionally encouraged to do this since it is known that the $S_q$ currents flow in opposite directions in high and low numerical latitudes, and, as described above, our study of $E$-layer diurnal abnormalities suggests the intervention of some perturbing agent which has opposite influences in high and low latitudes. Now it is an important characteristic of the $S_q$ system that the overhead currents constituting it attain their maximum value, not at noon, but at about 1000–1100 h. local time. We were therefore led to look carefully for any abnormalities in $h(N_m)$ or $N_m$ at that period of the day, in view of equations (3) and (4). Unfortunately, values of $h(N_m)$ were not available, so we were obliged to use values of $h'E$, the height of the under-boundary of the $E$ layer, instead.

In Fig. 1 are shown the diurnal variations of $h'E$ and of $N_m$ for Slough over the summer months of the year. On the same diagram is marked the approximate local time when the overhead $S_q$ current (and the corresponding value of the horizontal north-seeking magnetic force, $X_q$) reach their maximum value. It will be at once apparent that, at this particular local time, the value of $h'E$ is abnormally decreased, while the value of $N_m$ is similarly reduce These results, we therefore submit, indicate that t $S_q$ current system can markedly influence $E$ lay phenomena and encourage us to count such an agen as likely to be one of the major perturbing facto responsible for the divergences we have identifi between $E$ layer behaviour and the Chapman theor

We may first note a very simple result of electr dynamical theory. Since, at Slough, the $S_q$ curre flows from east to west, athwart the northwar horizontal component of the earth's magnetic fiel we should expect the velocity of drift to be dow wards; and, as equation (4) indicates, we shou then expect the height of the layer (as measured l $h(N_m)$ or $h'E$) to fall in sympathy. We note th the abnormal variation of $h'E$, at the time of ma imum overhead east-to-west current, has just tl sign to be expected. It is, however, a novel resul which could not have been predicted, that $\delta N_m$ an $\delta(h'E)$ are of the same sense. Since only the fir term on the right-hand side of (4) is of numeric significance here, we can deduce, from (3) and ( together, that $v$ and $\frac{\partial v}{\partial h}$ are of opposite sign. In oth words, we find that, when the $S_q$ current flows fro east to west, both the velocity of drift and the laye height variation are downwards; while at the sam time the drift velocity falls off with increasing heigh leading to a reduction of the layer-ionization ma imum $N_m$. We have now only to assume that a these ionospheric changes are reversed in sense in lo latitudes (where, as we know, the $S_q$ current flow from west to east) to be able to explain the $E$ laye anomalies mentioned above. In low latitudes, fo example, due to the fact that the $S_q$ current syste is not situated symmetrically to the local noo meridian, the $E$ layer is subject to vertical drif effects which are different in the forenoon and after noon. Such vertical drift causes a marked enhance ment of $N_m$ in the forenoon, which so far disturb the natural diurnal asymmetry of $N_m$ as to caus both $\Delta t$ and $\Delta N_m$ to become negative, instead o positive, as simple theory would require.

Now although the $S_q$ system of overhead current is not situated quite symmetrically with respect t the noon meridian, its influence is generally exerte in the same sense over practically the whole of th middle of the day. Our study of abnormal diurna asymmetry in $N_m$, as described above, shows that a west-to-east $S_q$ current tends to raise the value o $N_m$, while an east-to-west $S_q$ current tends to reduc it. We can therefore see that the overall effect o such an agency of vertical drift is to influence the general level of $N_m$ in different ways in different latitudes; in low latitudes $N_m$ is increased, at the latitude of the $S_q$ current focus $N_m$ is sensibly un-altered, while in still higher latitudes $N_m$ is decreased. We are therefore encouraged to consider whethe this simple general result, obtained from a study o the abnormal diurnal behaviour of the $E$ layer, als explains any of the other abnormal features of the $E$ layer which have been described in recent years.

Now Appleton[6] has shown that, while the value of $N_m$ in the $E$ layer is closely dependent on the solar zenith distance, it is not uniquely dependent on $\cos\chi$. There is, additionally, a tendency for the value of $N_m$ to be high in low latitudes. For example, at the equinoxes, the contours of the geographical locations of constant $N_m$ are not circles, with the sub-solar point as centre, as would be expected if were uniquely dependent on cos χ. They are, stead, of elliptical shape, the major axis lying ong the equator. Again, in June and December at noon, it has been found that $N_m$ does not attain its maximum value at the sub-solar point but at a titude displaced therefrom by some 10° towards he equator. It will readily be seen that both hese anomalies are also explicable in terms of a erturbation which, *ceteris paribus*, causes $N_m$ to be greater in low latitudes than in higher latitudes. Moreover, a further study shows that these two anomalous features of $E$-layer morphology, namely, he abnormal diurnal asymmetry and the latitude dependence of $N_m$, are quantitatively reconcilable.

Finally, it may not be out of place to indicate hat we consider to be the significance of these sults in the general development of ionospheric tudies. Many years ago it was boldly suggested by Balfour Stewart[7] that the daily rhythmic variations f the earth's magnetic field might be due to circulating electrical currents in the upper atmosphere. The geomagneticians then indicated the intensity and configuration of the upper-atmospheric current system which would be required. The discovery of the ionosphere and the elucidation of its properties by radio sounding has shown that the upper atmosphere is, in fact, sufficiently conducting to be the location of such currents; and the work now described has confirmed the presence of ionospheric currents, of the type prescribed, by way of the distortion they engender in the medium in which they flow.

# THE UNIVERSITY OF EXETER

By Prof. HUBERT T. S. BRITTON

Professor of Chemistry

ON October 28 the granting of the Royal Charter, reconstituting the former University College of he South West as the University of Exeter, was approved by an Order in Council at the meeting of he Privy Council, presided over by H.M. The Queen. The Charter appoints Mary, Duchess of Devonshire widow of the tenth Duke of Devonshire) as the first chancellor of the University of Exeter; Mr. B. G. Lampard-Vachell, deputy president of the College, as a pro-chancellor; and Dr. James W. Cook, principal of the College and formerly regius professor of chemistry in the University of Glasgow, as the first vice-chancellor.

This marks the culmination of the struggle to make Exeter the centre for higher education which began so far back as 1861, when Sir Stafford Northcote later the Earl of Iddesleigh) outlined his proposals for education at a meeting in Exeter in which he stressed the importance of making the city, "for which I believe it has natural and acquired advantages, a centre of Education for the West". A considerable sum was raised by subscription for the provision of premises for such an institution, and in 1862 a meeting was held to consider how this money could best be used to establish a memorial to the Prince Consort. It was decided that the memorial should be a museum with adjuncts for the study of art, science and literature, and the comments made by the Earl of Devon were prophetic in that the memorial would 'continue to future generations the special benefits for which the person to be honoured had in his lifetime devoted himself". In 1865 the erection of the Royal Albert Memorial was begun, and in it evening classes were held in preparation for the Science and Art Department examinations of South Kensington, and there were also extension lectures given under the auspices of the University of Cambridge.

This type of education developed, and a full-time principal, Mr. A. W. Clayden, was appointed in 1894, a part of his salary being paid by the Local Lecture Syndicate of the University of Cambridge. Extensions of the Royal Albert Memorial became necessary, and one of these was opened in 1895 by the Duke of Devonshire, chancellor of the University of Cambridge. In 1897 the foundation stone of yet another extension, known to-day as the York Wing, was laid by the Duke of York, later King George V. This is the only part of the Memorial Building that is still used by the College, the rest being occupied by the Museum, Art Gallery and College of Art.

The session 1901–2 was notable in the history of the College, for it was then that courses were first devised to prepare some students for the London external degrees of B.A. and B.Sc., and in that year the College was recognized as a day training college for women, Mr. Clayden then becoming principal of the Royal Albert Memorial Museum, Library and College. In 1903 the College was recognized as a day training college for both men and women.

In 1904 the Exeter City Council sought the advice of Prof. (later Sir) Michael E. Sadler, of the Victoria University of Manchester, on the best way of coordinating and developing the educational work of the City, and in his report he stated that "Exeter is the educational metropolis of the west", and ended by asking the question, "Can we feel surprise, therefore, that the Royal Albert Memorial College shows many signs of its capacity to become the University College of the West". He records that in July 1904 there were four students preparing for final B.A. and B.Sc., seventeen for intermediate arts and science, thirty-six for London matriculation, eight for preliminary medical examinations and a hundred for the teachers' certificate of the Board of Education.

The College grew and by 1906 more spacious premises were required, and they are the buildings now occupied by the Arts Faculty. Whereas the cost of the original buildings was defrayed almost entirely from public subscriptions made by people living in Devon and Exeter, the cost of this building (£25,000) was met by the City of Exeter, except for a contribution of £6,400 made by the Board of Education.

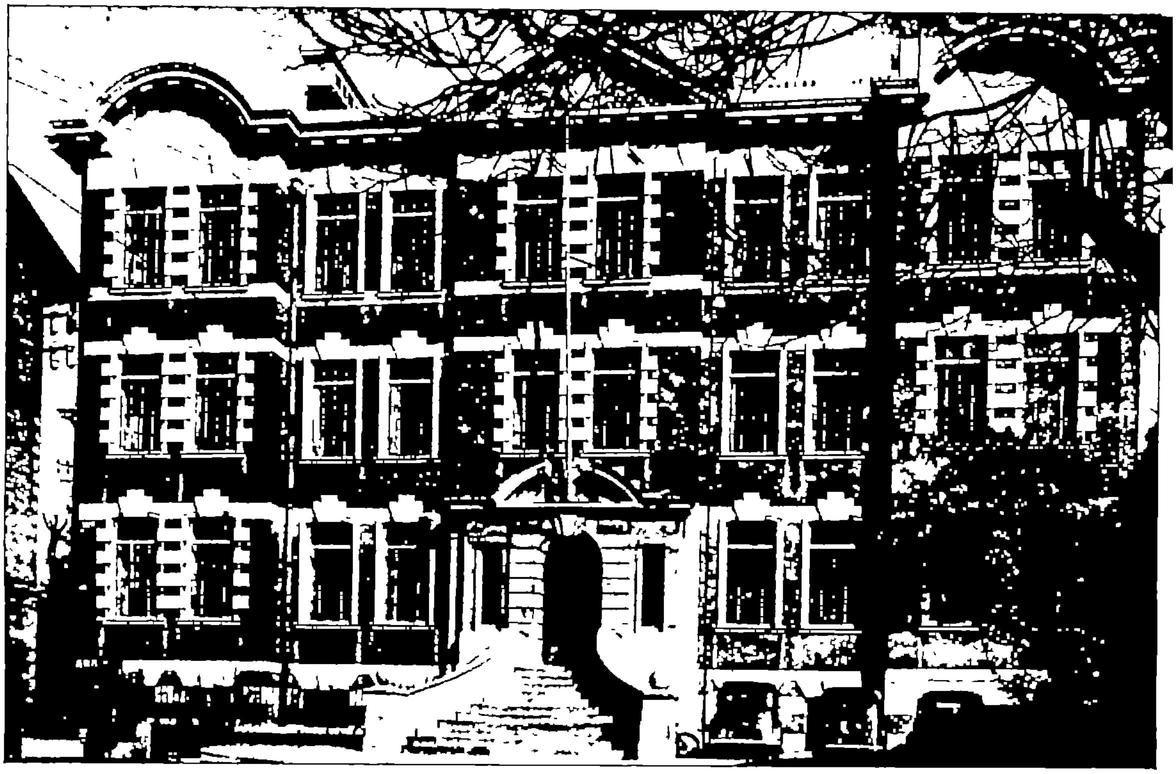

Fig. 1. University of Exeter: the Arts Faculty Building, Gandy Street

At this time the College was in straitened financial circumstances, and in 1912 an appeal for £30,000 for an endowment fund was launched; but the target was not achieved owing to the outbreak of the First World War.

In spite of repeated objections which were raised by the Board of Education, the City Council adopted the designation Royal Albert Memorial University College in 1908; but it was not until 1918 that it was recognized *de facto* as a university college, though it was not actually placed on the University Grants List of the Treasury until July 26, 1922. Principal Clayden (died 1944) retired in 1920 and was in April of that year succeeded by (later Sir) Hector J. W. Hetherington, who came from University College, Cardiff, where he had been professor of philosophy. He resigned in December 1924 to take the chair of philosophy at Glasgow, later to become vice-chancellor of the University of Liverpool, and is now vice-chancellor and principal of the University of Glasgow.

In its first two principals, University College, Exeter, has been twice blessed. Clayden was a man of vision who realized the need for university education in the south-west of England, and Hetherington, believing that the need was real, was able to persuade the Treasury to include the College at Exeter in the list of university institutions. In 1915, in his presidential address to the Devonshire Association, Principal Clayden forecast a University for the South West and described what he considered to be the scope of the University. Now that the University has become a reality, no doubt serious consideration will be given to his ideas.

From the time of its incorporation, the University College increased in numbers of students and staff and in academic attainment, due in no small measure to a succession of enthusiastic and energetic principals. They were Sir Walter Moberly (1925), who left in 1927 to become vice-chancellor of the University of Manchester, Dr. John Murray (1926–51), Prof. F. H. Newman (acting 1951–52), who died suddenly in 1952, Prof. S. H. Watkins (acting 1952), Sir Thomas Taylor (1952–53), who died suddenly in 1953, Prof. H. B. Garland (acting 1953–54), and the present vice-chancellor, Dr. James Wilfred Cook. The untimely deaths of Prof. Newman and Sir Thomas Taylor caused the submission of the petition for the grant of university status to be delayed until after Dr. Cook had assumed the office of principal.

The first president of the University College of the South West was H.R.H. the Prince of Wales; but on his accession to the throne as Edward VIII, Sir Henry Lopes (later Lord Roborough) was elected to that office, which he held until his death in 1938. Lord Cranborne (now Lord Salisbury) then became president, and it is a disappointment that, owing to the pressure of his other obligations, he was unable to allow his name to go forward as the first chancellor of the University of Exeter, towards the creation of which he has done so much.

Among the College benefactors may be mentioned Mr. E. J. Mardon, the late Lord Roborough, the late Mr. Washington Singer, the late Mr. C. V. Thomas, the late Mr. A. C. Ballard, the late Sir William Reardon-Smith, and the late Alderman W. H. Reed, at one time Mayor of Exeter. It was he who in 1922 gave to the College, Streatham Hall, a large mansion built in the Italian Renaissance style and now renamed Reed Hall, with its beautiful gardens and arboretum of eight acres, in the hope that the College would purchase the surroundings fields of more than a hundred acres to form the campus for the Univer-

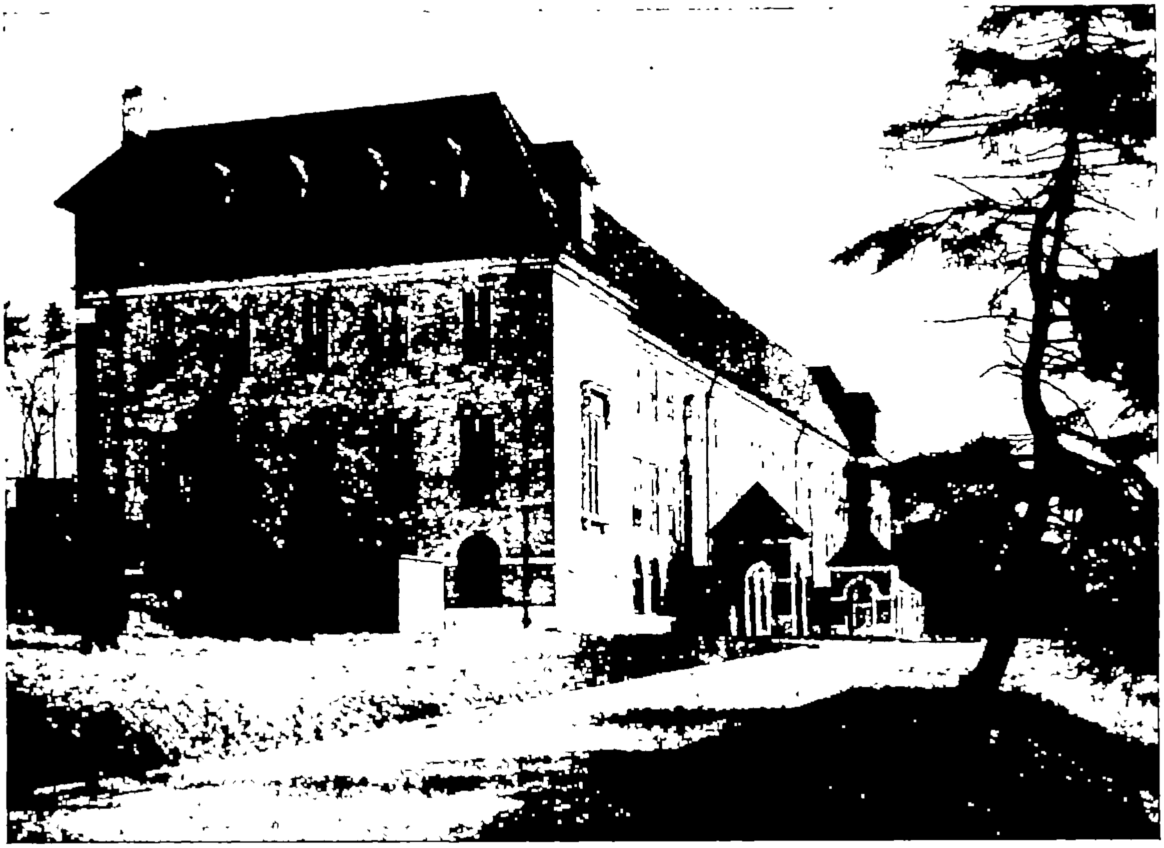

Fig 2. University of Exeter: Washington Singer Laboratories

sity. It is that provision which has placed the University of Exeter in such a pleasant setting.

Exeter is an ideal seat for a university. Several of the newer buildings of the University already occupy prominent positions on the University campus at Streatham, consisting of some 150 acres, which for beauty is probably unsurpassed by that of any other university institution in the United Kingdom. Its natural beauty is enhanced by the panorama of the varied Devonshire landscape that is to be seen from its slopes. It is situated about a mile north-west of the old buildings.

The original buildings are almost within a stone's throw of the Cathedral. Before the First World War they and the York Wing housed the entire College; but afterwards increased accommodation had to be found. This took the form of several rather unsightly ex-army huts, some of which were destroyed in the air raids of 1942. In 1931 the congestion in the Gandy Street buildings was partially relieved by the removal of the Departments of Chemistry and Physics to the new Washington Singer Laboratories on the University campus; but further relief did not come until 1939, when the library was transferred to the new Roborough Library, and again in 1953 when the Botany, Zoology and Geology Departments migrated to the new Hatherly Laboratories (see *Nature*, 171, 860; 1953). In consequence, it was found possible to allocate a few rooms in the old building to the Guild of Undergraduates; but there still remains a real need for more space for the social requirements of the students.

The increase in the numbers of students reading, and carrying out research, in chemistry and physics renders imperative the need for additional accommodation. The Roborough Library is filled almost

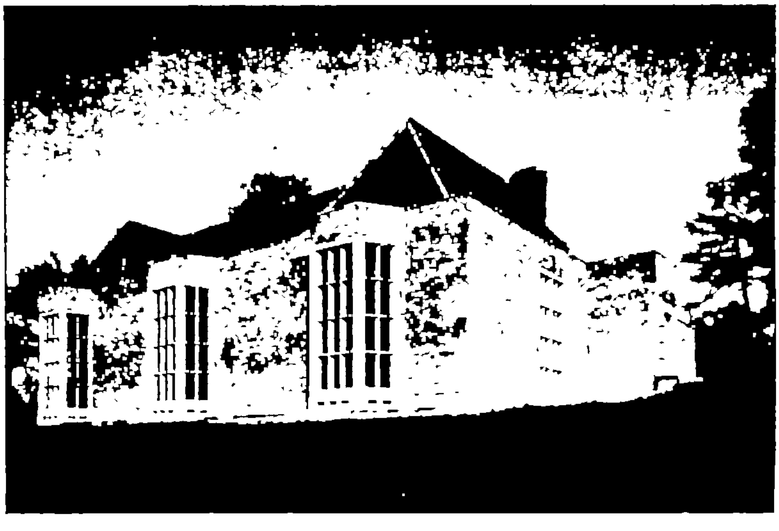

Fig. 3. University of Exeter: Roborough Library

Fig. 4. University of Exeter: Reading Room, Roborough Library

to capacity with nearly 100,000 volumes. The erection on a rather elevated site of a new block for the Faculty of Arts is imminent. The architect of the Singer and Hatherly Laboratories and the Roborough Library and two Halls of Residence, Mr. E. Vincent Harris, is giving the University a chapel, to be known as the Mary Harris Memorial Chapel. Building will shortly begin.

Situated still higher on the southern slope of University campus are the Mardon and Reed Halls of residence for men, while on the top of the hill, which since the War has been levelled, is located a large playing field. By its side is the Taylor Pavilion —a memorial to the late principal, Sir Thomas Taylor. The facilities for sport have just been extended by the erection of a boat-house at Countess Weir on the bank of the Exe canal.

Contiguous with the campus is Knightley, in which the Faculty of Law and the Overseas Students' and Extra-mural Departments are housed, and Thornlea, which, together with a new building close by, accommodates the Department of Education and Psychology and the Institute of Education.

An important policy of the College was to make it residential so far as possible, and in the years immediately prior to 1946 this aim was almost realized; but since then, despi substantial efforts made by t College to acquire suitable premise the influx of students has made necessary for some to live in priva lodgings for a part of their stay i Exeter. Of the 1,029 full-tim students, who come not only fro the south-west of England but al from London and elsewhere in Eng land and Wales and from man overseas countries, 558 live i College halls and the remainder liv either at home or in lodgings.

Since its incorporation as a University College, remarkable stride have been made in the training provided for the London externa degrees in arts, science, economic and law. The number and qualit of the degrees obtained serve as a indication of the high academi status which has been attained. No has this progress been confined t undergraduate training, for considerable attention ha been given to postgraduate training and research. In the sciences, research has been a strong feature, as may be seen from the number of original papers published in the scientific journals and the number of Ph.D.'s which have been gained by Exeter students. Facilities for research in astronomy are also available in the Norman Lockyer Observatory at Sidmouth, which for many years past has been closely associated with the University College. On the arts side, abundant material for investigation has been rendered available to the students by the recent agreement of the Dean and Chapter of the Cathedral to entrust the College Librarian with the care of the unique library of the Cathedral.

For the time being, the University of Exeter will develop and consolidate its existing Faculties of Arts (including Education), Science, Social Studies (including Economics, Social and Public Administration) and Law. Nevertheless, it is safe to say that the possibility of extending its usefulness in other fields of learning and research will always receive the constant vigilance and attention of the new University. Its aspirations and aims will always be to serve mankind, the United Kingdom and especially the inhabitants of the south-west of England.

---

# INTERACTION OF SPRAY PROGRAMMES AND INSECT POPULATIONS

An open day at East Malling Research Station on September 21 provided an opportunity for some two hundred members to hear and discuss contributions by staff of the Entomology and Plant Protective Chemistry Sections on the interaction of spray programmes and insect populations. Following the usual custom, members of the official advisory services attended a similar programme on the previous day.

It was pointed out that the present investigations, which are devoted to a study of the fruit-tree red spider mite, *Metatetranychus ulmi* (Koch), its natural enemies, and the effect of spray chemicals on populations of both, are a collaborative project shared by entomologists, plant-protective chemists and plant pathologists. The entomologists are primarily concerned with the biological and ecological problems involved, the chemists with the mechanism of action by which the spray materials in common use affect the insects and mites and, since there is ample evidence to show that fungicides as well as insecticides sometimes prove harmful to the beneficial fauna, the plant pathologists also become intimately involved in such a project. At the present time only a progress report is possible; the causes leading to the appearance of *M. ulmi* as a pest are fairly clear, but much detailed work lies ahead before a spray programme can be devised by which beneficial insects are retained in the fruit plantation while ests and diseases not amenable to control by natural gencies are kept in check by the application of chemicals.

Historically, *M. ulmi* has been noticed as a pest in English orchards only during the past thirty years, its appearance coinciding with the use of tar distillate washes which became general from 1925 onwards. More recently, infestations have been ccentuated following the use of DDT and parathion s post-blossom sprays and, in some Kent and Essex apple orchards, the red spider mite, *Tetranychus telarius* L., has appeared as a pest for the first time following frequent applications of parathion during he summer months. Examples such as these clearly indicate that harmful side-effects may arise from the use of new spray chemicals ; and since such materials are often in the hands of growers before members of esearch institutions have time to evaluate their full effects on the orchard fauna, it is only prudent for hem to be used on a small scale at first, followed by close and frequent observation, so that remedial measures can be taken at the earliest moment should the need arise.

As a result of intensive surveys in both sprayed and derelict orchards, about a hundred species, comprising approximately equal numbers of insects, and spiders and mites, have been found that utilize in varying degrees *M. ulmi* as a source of food. Striking differences occur between the fauna of these two orchard types. In derelict orchards a large number of species occur, forming a continuous succession, so that predators are represented in strength throughout the year, attacking the mite during the whole of its active period and also feeding on the winter eggs. In sprayed orchards there is usually a total absence, or at least a very marked reduction, of predators until June ; for the remainder of the summer the species are much fewer, although individual insects such as the black-kneed capsid, *Blepharidopterus angulatus* (Fall.), are often present in considerably greater numbers than in unsprayed orchards. Only minor annual fluctuations of both species and total populations occur in the derelict orchard, whereas both show violent variations in the sprayed orchard. In part this can be accounted for by the direct effect of sprays, but alternative sources of food, other than phytophagous mites, readily available only in derelict orchards, must also be an important contributory factor.

Among the insect predators, those occurring most commonly include species of Miridae (*Psallus ambiguus* (Fall.)), *Campylomma verbasci* (M.-D.), *Atractotomus mali* (M.-D.), *Orthotylus marginalis* Reut., *Phytocoris* spp., *Malacocoris chlorizans* (Panz.), *Blepharidopterus angulatus* (Fall.)), Anthocoridae (*Anthocoris nemorum* (L.), *Orius majusculus* (Reut.)), Coccinellidae (*Stethorus punctillum* (Wei.)) and Coniopterygidae (*Conwentzia* spp.). Of the spiders, only members of the families Theridiidae and Linyphiidae readily feed on *M. ulmi* ; and the predacious mites are predominantly species of the genus *Typhlodromus*, of which only *T. tiliae* Oudms. becomes abundant in sprayed orchards.

The relative importance of each predator has not yet been fully assessed ; but field observations indicate that all the insects named possess the desirable character of being 'density dependent' in the sense that numbers increase in the presence of ample food, whereas the spiders, with at most one generation a year, increase their rate of feeding when food is plentiful. The latter group attack both beneficial and pest species indiscriminately, and are therefore of doubtful value except under conditions where the pest predominates. Judged by the usual standards, *Typhlodromus tiliae* is an inefficient predator, as its behaviour pattern both in respect to leaf preference and position on the leaf is not well integrated with that of *M. ulmi* ; furthermore, it has a low feeding capacity and can develop and reproduce on plant protein or other species of mites.

As an introduction to the orchard trials in progress at East Malling, the effects arising from two extreme ecological situations were described in very simplified form. In one example, a succession of natural enemies present in the same environment as the prey and attacking it throughout its life-cycle resulted in a continuous depression of prey population similar to that already observed in connexion with *M. ulmi* in derelict orchards. But under such conditions alternative sources of food are necessary if predator populations are to be maintained. As yet, relatively little is known about this aspect ; but experiments have demonstrated that the Mirids and Typhlodromid mites are partly phytophagous, and it is also clear that the much richer fauna, including pest species such as aphids and *Psylla mali* Schmid., occurring in the unsprayed orchard, can provide adequate food for the predators. In contrast to the above, the violent oscillations associated with the presence of only a single species of predator and prey were outlined. Examples of this type are rarely documented in Nature except in specialized ecological niches, but it appears that man may have created such a situation in sprayed orchards between *M. ulmi* as prey and *B. angulatus* as predator. A composite picture from the records of two experimental orchards over the past three years has shown one complete oscillation, two stages of which were available as a visual demonstration. In one orchard, where the population of *M. ulmi* was approaching its peak and predator populations were increasing annually but not yet large enough to cause suppression, the foliage was markedly bronzed, whereas in another orchard, where mite populations suffered a severe reversal in 1954, the fresh green foliage bore no evidence of injury, even in the absence of any acaricidal sprays.

Investigations concerning the effect of spray chemicals on populations of *M. ulmi* and its predators are still in the analytical phase, being concentrated on elucidating the harmful effects of insecticides in general use during the pre-blossom period, together with a similar study of fungicides when applied throughout the spraying season. Sufficient data have been obtained to demonstrate that, by ovicidal or contact action, DNC(dinitrocresol)-petroleum applied at the delayed dormant stage destroys practically all the predators which would normally be present before June ; DDT, by contact or residual action, has a similar effect when applied at the mouse-ear stage ; lime-sulphur drastically reduces Typhlodromid mites and causes a slight reduction of Mirids. Studies of the age structure of certain Mirid species following the use of captan (*N*-trichloromethylthio-*cyclo*hex-4-ene-1 : 2-dicarboxyimide), a fungicide considered non-toxic to these insects, have indicated that even the physical effect of sprays applied at high pressure by the conventional hydraulic equipment may seriously affect predator populations.

The very harmful effect on beneficial species of certain insecticides used for controlling pests during the pre-blossom period has therefore been clearly demonstrated; it can also be deduced from indirect evidence that chemicals in current use against the apple sawfly, *Hoplocampa testudinea* Klug, will produce similar results. In addition, it has been shown that the range of predators occurring from June onwards is unable to prevent large oscillations in the population of *M. ulmi*. The aim, therefore, is to modify the spray programme in order to allow the establishment o one or more efficient predators early in the season Further advances along these lines will be largel dependent on the chemical studies now in progres concerning the fate of materials after depositio on the tree. By increasing knowledge in thi sphere, it may be possible to achieve rather mor selective action by choice of chemical and variations in its time of application, concentration o formulation.

# METABOLISM OF NITROGEN IN PLANTS

A SESSION on the nitrogen metabolism of plants, under the chairmanship of Prof. M. Skene, was held at Bristol on September 2 by Section K (Botany) of the British Association. Problems of the assimilation of nitrogen and the synthesis of amino-acids and proteins in plant tissues formed one of the central themes of the discussion. Three speakers gave accounts of some of the work in progress in the Department of Botany of the University of Bristol, and Prof. H. E. Street (University College of Swansea) discussed the potentialities of the aseptic culture of excised roots as a means of studying the assimilation and metabolism of nitrogen.

The part played by different cellular structures in the synthesis of proteins was dealt with by Prof. E. W. Yemm (Bristol). Earlier views, derived chiefly from genetical considerations, have suggested that the nucleus is the most important centre of protein synthesis in the cell, and this hypothesis has been developed particularly by Caspersson. The conspicuous changes of nucleic acids associated with protein synthesis in some animal cells and in micro-organisms provide the chief support for the hypothesis. During recent years several lines of evidence have been advanced which are difficult to reconcile with the view that protein synthesis is entirely localized in or on the surface of the nucleus. For example, Brachet and his collaborators have shown that non-nucleated fragments of some plant and animal cells continue to synthesize proteins actively. In addition, experiments with isotopically labelled amino-acids indicate that they are rapidly incorporated into particulate structures of the cytoplasm. Ultramicroscopic particles, which may be separated by differential centrifugation and which contain most of the ribonucleic acid of the cytoplasm, are especially active in the incorporation of radiocarbon-labelled amino-acids. It has therefore been suggested that these cytoplasmic microsomes are the chief centres of protein synthesis in cellular metabolism.

There are, however, several difficulties in the interpretation of data based solely on the incorporation of labelled amino-acids into cell proteins. The study of proteinases and other plant enzymes has shown that they promote exchange reactions, such as transpeptidation and transamidation, so that replacement of amino-acids does not necessarily imply a new synthesis of protein. Experiments with detached leaves and roots of barley have shown that, even under conditions in which a net loss of proteins occurs in the tissues, there is nevertheless appreciable incorporation of the isotope nitrogen-15 into the cytoplasmic proteins. On the other hand, under conditions in which an active synthesis of new proteins occurs, such as in young seedlings, it i possible to detect the incorporation of nitrogen-1 into all the cell components separated by differentia centrifugation within a few hours of supplying th isotope as an ammonium salt. The results so fa obtained from a study of the assimilation of nitrogen-15 by barley seedlings suggest that the primary synthesis of new protein is not confined to microsomes but may also take place in nuclei, plastids and mitochondria of the cells.

Dr. A. J. Willis (Bristol) discussed the assimilation by plants of simple inorganic forms of nitrogen, such as nitrates, nitrites and ammonium salts, and gave an account of experiments in which an attempt was made to trace the early stages of the assimilation process and to determine the nature of the primary products formed in young roots of barley. Under conditions favouring a rapid uptake of nitrates, nitrites or ammonia by excised roots, it was found that a marked increase of glutamine, accompanied by smaller quantities of asparagine, occurred in the tissues. During short periods of assimilation more than 90 per cent of the nitrogen metabolized could be recovered as amides, chiefly glutamine. By using nitrogen-15 as a tracer it was possible to obtain decisive evidence that the amides were primary products of assimilation. When the roots were supplied with an ammonium salt containing about 30 atom per cent excess of nitrogen-15, the isotopic abundance in the amino- and amide-groups of glutamine rapidly approached that of the ammonia supplied. Some differences were apparent in the amount of amides formed when different sources of nitrogen were provided: nitrite and ammonia were more rapidly metabolized in the young roots than nitrate, the step nitrate to nitrite being a slow one. All the data support the hypothesis that nitrite, hydroxylamine and ammonia are intermediates in the assimilation of nitrate and that glutamine is a primary product of synthesis.

Other metabolic activities of the roots are closely associated with the assimilation of nitrogen. The rate of respiration, measured by the uptake of oxygen and the production of carbon dioxide, is greatly increased when a suitable source of nitrogen is provided. The most rapid responses are obtained with ammonia and nitrites, and there are many indications that the rise in respiration is coupled with synthetic activities in the tissues rather than with salt uptake. An extensive breakdown of carbohydrate sustains the assimilation processes in excised roots for a limited period, and analytical data indicate that both the respiratory carbon dioxide and the carbon skeletons for the synthesis of amides are mainly upplied by glycolysis. Some recent evidence sug-ests that the close coupling between respiratory ctivity and the metabolism of carbohydrates and trogen may occur within the mitochondria, which ppear to be the chief centres of the metabolism of utamic acid and glutamine in the cell.

Somewhat similar experiments carried out on the ssimilation of ammonium salts by food yeast (*Torulopsis utilis*) have given results in many respects imilar to those outlined above. The rate of respira-on and carbohydrate breakdown show a marked ncrease, while glutamine and glutamic acid, together ith smaller amounts of alanine, have been identified s the chief products of assimilation accumulating at irst in the cells. Here again, the key position of glutamic acid and glutamine in the assimilation of itrogen is indicated.

The metabolism of amino-acids, and particularly their relation to protein synthesis, was discussed by Dr. B. F. Folkes (Bristol). In plant tissues, most of the nitrogen is combined in complex proteins which contain an array of some eighteen different amino-acids. Analyses of different proteins show that, lthough similar amino-acids are generally present, heir proportions vary widely. This is particularly evident in the analyses of reserve proteins found in seeds and other storage organs, although the cyto-plasmic proteins appear to be relatively constant in composition throughout the plant kingdom. A systematic study of the proteins of barley grains and their changes during germination has thrown some light on the metabolism of amino-acids in the young seedling.

With regard to the relation between amino-acids and protein synthesis in plants, two distinct types of hypothesis have been advanced: the so-called amino-acid hypothesis suggests that amino-acids are first formed and are then combined into the polypeptide structures of proteins; alternatively, it is suggested that proteins are synthesized by complex condensations of metabolites without the intervention of amino-acids. The results obtained from an investigation of the nitrogen metabolism in barley seedlings are consistent with the amino-acid hypothesis. If the grains are germinated without external supplies of nitrogen, the formation of new proteins in the embryo is entirely at the expense of the reserve proteins of the endosperm. Analyses show that 75 per cent of the amino-acids required for protein synthesis in the developing embryo could be derived direct from the endospermic proteins; but, on the other hand, certain amino-acids show large changes as germination proceeds. An increase of aspartic acid, alanine, lysine and arginine occurs at the expense of glutamic acid, amide and proline, which are present in large amounts in the reserve proteins. These results strongly suggest that glutamic acid and glutamine are the chief precursors in the synthesis of other amino-acids, and in this regard the data offer a close parallel to those obtained during the assimilation of external supplies of nitrogen. The presence of transaminases which promote the interconversion of glutamic acid and at least six other amino-acids has been demonstrated in young barley embryos. These and other enzymes which bring about the interconversion of glutamic acid and proline appear to occur mainly in the mitochondria, and the mechanisms underlying the transformation of amino-acids may in part determine the close relation between nitrogen metabolism and cellular oxidations.

Evidence from several other directions now gives support to the amino-acid hypothesis. It has been shown, for example, that isotopically labelled amino-acids may be incorporated into tissue proteins of plants and animals while, particularly in micro-organisms, amino-acids may act as specific nutrients. The close connexion between nitrogen metabolism and respiration in plants, which has generally been regarded as favouring the alternative hypothesis, can be more simply interpreted in terms of the synthesis and interconversion of amino-acids and the energy requirements of peptide formation.

In a discussion of the nitrogen nutrition of excised roots, Prof. H. E. Street directed attention to the advantages which may be gained from the use of aseptic organ cultures. Metabolic interrelations between the separate parts of the plant body may be studied, thereby enabling sites of synthesis to be identified. The aseptic conditions of culture permit critical feeding experiments with organic or inorganic forms of nitrogen under closely controlled conditions in which experimental responses can be assessed in terms of both biochemistry and growth. In addition, the use of clonal material, readily multiplied, ensures genetic uniformity. At the same time, excised organ culture can expose genetic characters obscured in work with whole plants, making available tissues with distinctive metabolisms.

Some of these potentialities are being exploited in current researches into the nitrogen nutrition of aseptically cultured excised roots. For the first time, experimental conditions have been defined for the growth of excised roots on nitrate, nitrite and ammonia. Ethylenediamine tetracetate at an appropriate concentration is used to ensure availability of iron, and sparingly soluble calcium phosphates and calcium carbonate are employed as buffers. In the media used, there are sharply distinct *p*H optima for growth with each different inorganic nitrogen source: *p*H 7·0–7·5 for ammonium, *p*H 4·3–5·0 for nitrate and *p*H 5·5–6·5 for nitrite. These optima do not seem to be explicable simply in terms of a direct effect of *p*H on either the absorption or assimilation of nitrogen.

Roots grown on different inorganic nitrogen sources show characteristic differences in the composition of their alcohol-soluble nitrogen. Ammonium roots are rich in ammonium, amide and free amino-acid nitrogen and low in 'other' or 'residual' nitrogen, the relative magnitude of these fractions being reversed in roots grown in nitrate. Nitrite roots contain nitrite nitrogen, but otherwise resemble ammonium roots in composition. When extracts are examined chromatographically, clear-cut differences, depending upon nitrogen source, are revealed in the range and relative amounts of the individual amino-acids present. These investigations are being extended to study the effects not only of nitrogen source but also of carbohydrate and mineral status on the nitrogenous composition. The influence on nitrate-reducing ability of prolonged culture of roots in ammonium nitrogen is being studied, and the nitrate-reducing abilities of excised roots from different species and genetic strains are being compared.

The growth of excised roots from certain species has been found to be markedly stimulated by amino-acids. For example, stimulations of growth of different geographical strains of excised groundsel roots are observed with amino-acids of the ornithine cycle. With the roots of other species, externally supplied amino-acids are toxic. Individual amino-acids differ markedly in their toxicity, and in some instances the relations between toxicity and concentration are complex. Use of amino-acid mixtures has revealed 'amino-acid antagonisms', the mixtures being usually less toxic than their constituents. Very strong antagonisms have been shown between certain pairs of amino-acids of similar chemical structure.

Investigations of the nitrogen nutrition of excised tomato roots have revealed that dimethylaminoethanol, ethanolamine, glycine, choline and certain other nitrogenous compounds can replace the growth requirement of the roots for pyridoxine (vitamin $B_6$). These replacement effects throw some light on the part played by the vitamin in the metabolism of the roots and further illustrate the ability of the technique to expose new topics in plant physiology.

# OBITUARIES

## Dr. L. C. Thomson

THE untimely death on October 10 of Lewis Charles Thomson in his forty-third year comes as a shock to his many friends and colleagues; for Thomson was a model of vigorous health, and the illness to which he succumbed was, mercifully, brief.

Thomson entered Guy's Hospital from Sherborne in 1932. As a medical student he gained several distinctions—the Hilton Prize for dissection in 1933, the Michael Harris Prize for anatomy and the Junior Proficiency First Prize in 1934—and held demonstratorships in histology, anatomy, bacteriology and pathology. He qualified M.R.C.S., L.R.C.P. in 1937, and M.B., B.S. in the following year.

While at the Hospital, Thomson held in succession the complete series of appointments from clinical assistant to house surgeon. But Thomson was not destined for an ordinary medical career. His interests were teaching and research. Consequently, in 1940, he joined the staff of the Medical School at Guy's, first in the Anatomy Department, and then, between 1942 and 1947, in the Department of Physiology.

During this period he worked on a number of problems, among which was the preparation of an inorganic solution which had an equal optical density for all wave-lengths within the visible spectrum (Thomson's Grey Solution). In after years he took pleasure in mystifying the uninitiated with this smoky-looking solution and was highly delighted if asked how the carbon was kept in suspension. His main contributions at Guy's, however, were to vision, and in 1948 he received his Ph.D. for a thesis on the part played by the nervous system in visual adaptation.

With such a background it was natural for Thomson to join, in 1947, the Vision Research Unit. This had just been formed at the Institute of Ophthalmology by Prof. H. Hartridge under the auspices of the Medical Research Council. In 1945, Prof. W. D. Wright had invited Thomson to collaborate on problems concerning the colour vision of small areas within the fovea. This fruitful association was continued after he had joined the Vision Research Unit and ceased only in 1951 when he assumed, on Hartridge's retirement, the directorship of the Unit, renamed the Group for Research in the Physiology of Vision.

In spite of his close attention to administrative detail, Thomson continued to prosecute his own researches with vigour, and at the time of his death had published more than twenty papers on visual topics. His more important contributions concerned the colour sensitivity and intensity discrimination of the central fovea, the influence of the light history of the eye upon the course of its dark adaptation, binocular summation within the nervous pathways of the pupillary light reflex, and the variations of hue discrimination with change of luminance level. Thomson also directed attention to the irregularities of shape in the equal-energy luminosity curve.

As a long-term project, Thomson had constructed apparatus for electro-physiological researches. He mastered the many technical problems involved in such work; but, just when it seemed that his labours were to be crowned with success, he had to lay down his tools. In the year of his death honours were coming fast to Thomson. He obtained his D.Sc. early in 1955; he delivered the twenty-seventh Ettles Memorial Lecture, and was to have been the first Edridge-Green Memorial Lecturer.

Thomson was a first-class administrator. He organized the British delegation to the Nineteenth International Physiological Congress in Montreal in 1953, and was chairman of the Colour Group of the Physical Society during 1953–55.

In spite of his intense pre-occupation with research and administration, Thomson had a number of other interests. He loved sailing, and navigated his boat across the North Sea and the Channel; he was also a keen photographer and an interested student of geology.

Thomson was a most likeable character; he was quiet, unassuming and possessed the rare blend of humility and steadfast purpose. He was a devout Christian and his life was guided by his deep religious beliefs. He will be sadly missed by his colleagues and friends. The deepest sympathy is extended to his widow, his two young sons and his widowed mother.

H. J. A. DARTNALL

## Mr. Alexander Gow

ALEXANDER GOW, who died on October 13, in his eighty-seventh year, performed a noteworthy service to the cause of scientific and technological education in Great Britain by reason of his administrative work as the first secretary of the then newly constituted Imperial College of Science and Technology, serving during the period 1908–34, which bore the first fruits of the fusion of the three constituent colleges, the Royal College of Science, the Royal School of Mines and the City and Guilds College, into an academic unit. An aspirant to the teaching profession, he was educated at the Borough Road Training College and Caius College, Cambridge. His early appointments were scholastic, and he served as principal of the Municipal Technical and Secondary School, Warrington, and as director of education for Blackburn, before undertaking his *magnum opus*, the permanent value of which was signalized by his election to honorary fellowship of the Imperial College in 1946.

Then, as now, no secretary of a college could escape the continuous pressure on reserves of knowledge, of divination, of judgment, and even of sheer physical effort which a responsible share in the shaping of its educational policy exercises. So far as those then associated with him in a less authoritative position uld penetrate an exterior reserve, it appeared that ow took such responsibilities easily in his stride. lways unruffled, precise, even pontifical in manner, e held in firm grasp the controls of a machine of teadily growing complexity, while maintaining xcellent relations with those responsible for the irection of academic studies and from time to time isclosing the warmth of sympathetic understanding hich characterized his unofficial relationships with llow members of the College. He served under four rectors: Dr. Henry Bovey, Sir Alfred Keogh, Sir Thomas Holland and Sir Henry Tizard. During his retirement, in which until recently he continued to enjoy the devoted companionship of his wife, he retained his interest in the affairs of the Imperial College through occasional correspondence with his former colleague and successor in office. The expansion of the College, now in progress, rests on foundations well and truly laid by men among whose names that of Alexander Gow occupies a worthy place.

# NEWS and VIEWS

### Royal Society Medals: Awards for 1955

THE following awards of medals have been made y the President and the Council of the Royal ociety:

*Copley Medal* to Sir Ronald Fisher, Arthur Balfour rofessor of genetics in the University of Cambridge, or his distinguished contributions to developing the heory and application of statistics for making uantitative a vast field of biology.

*Davy Medal* to Prof. H. W. Melville, Mason professor of chemistry in the University of Birmingham, for his distinguished work in physical chemistry and in polymer reactions.

*Sylvester Medal* to Prof. E. C. Titchmarsh, Savilian professor of geometry in the University of Oxford, for his distinguished researches on the analytical theory of numbers, and other branches of pure mathematics.

*Hughes Medal* to Prof. H. S. W. Massey, Quain professor of physics at University College in the University of London, for his distinguished contributions to atomic and molecular physics, particularly in regard to collisions involving the production and recombination of ions.

### Royal Society of Edinburgh: Officers for 1955–56

THE following have been elected officers and members of council for 1955–56 of the Royal Society of Edinburgh: *President*, Prof. James Ritchie; *Vice-Presidents*, Dr. A. H. R. Goldie, Prof. C. M. Yonge, Prof. Norman Feather, Prof. J. Norman Davidson, Principal H. B. Nisbet and Prof. Meirion Thomas; *General Secretary*, Dr. J. E. Richey; *Secretaries to Ordinary Meetings*, Dr. T. R. Bolam and Dr. A. W. Greenwood; *Treasurer*, Mr. A. W. Young; *Curator of Library and Museum*, Dr. Douglas Guthrie; *Councillors*, Dr. J. M. Cowan, Dr. David Jack, Prof. J. M. Robertson, Prof. D. Whitteridge, Prof. E. M. Wright, Prof. E. L. Hirst, Dr. D. E. Rutherford, Dr. D. A. Allan, Prof. G. H. Bell, Dr. D. N. McArthur, Dr. A. G. MacGregor and Prof. C. H. Waddington.

### Electrical Engineering at Birmingham: Prof. D. G. Tucker

DR. D. G. TUCKER, who succeeds Prof. A. Tustin at Birmingham (see *Nature*, 175, 148; 1955), has spent several years at the Post Office Research Station, where he was engaged on research and development work on telephone transmission, including the war-time development of special carrier telephone systems; in 1946 he was head of the Post Office Transmission Measurements Research Group. In 1950 he joined the Royal Naval Scientific Service at H.M. Underwater Detection Establishment at Portland, and he has resigned his post as a senior principal scientific officer at this Establishment in order to take the chair of electrical engineering in Birmingham. Dr. Tucker has had wide experience in telephone transmission research and in the development of very advanced types of under-water acoustic equipment. In addition, he has been engaged in applied research in electronics, acoustics, oceanography and operator problems. He holds the degrees of D.Sc.(Eng.) and Ph.D. in the University of London, and he has published a large number of papers dealing with electronic and transmission problems. He takes to Birmingham wide experience of applied research in the field of communications and electronics. In addition, he is a keen student of natural history, and he has published several papers on bird population studies in the *London Naturalist*, the journal of the London Natural History Society.

### Foundry Metallurgy at the Massachusetts Institute of Technology: Prof. H. F. Taylor

A NEW chair, the American Brake Shoe Company chair of foundry metallurgy, has been established at the Massachusetts Institute of Technology, and Prof. Howard F. Taylor, already professor of metallurgy and director of the Institute's Foundry Laboratory, has been appointed its first holder. Prof. Taylor graduated in chemical engineering and metallurgical engineering at Michigan State College and went in 1937 to the Naval Research Laboratory in Washington, D.C., where he later became head of steel casting research. He joined the staff of the Massachusetts Institute of Technology in 1945 and in 1952 became a full professor. Partly in consideration of his work during the Second World War, Prof. Taylor was awarded the Peter L. Simpson Gold Medal in 1946 by the American Foundrymen's Society and the Army–Navy Distinguished Civilian Service Award in 1948. The American Brake Shoe Company, which has more than fifty plants and is one of the leading foundry companies in the United States, has supported metallurgical work at the Institute with grants-in-aid, a graduate fellowship and undergraduate scholarships. During recent years the Institute's Foundry Laboratory has been greatly expanded, and it now provides some of the best facilities for research in this field in the United States.

### Zoology at Lucknow: Dr. M. B. Lal

THE Lucknow School of Zoology made great advances under the late Prof. K. N. Bahl (*Nature*, 174, 16; 1954), and good wishes for its continued progress will follow his recently appointed successor, Dr. Makund Behari Lal. Most of Dr. Lal's training has been at the University of Lucknow, where he graduated M.Sc. in 1928 and D.Sc. in 1937, and where as demonstrator in zoology (1929) and lecturer in the Department (1937) he showed his ability as a teacher and research worker. At the end of the Second World War he went to Great Britain and spent two years in the Zoology Department of the University of Edinburgh, developing his knowledge of the life-histories of various helminths in order to further this line of investigation in India. He was awarded the D.Sc. degree of Edinburgh in 1947, and on his return to Lucknow was appointed reader in zoology. Recently he represented India at the General Assembly in Rome of the International Union of Biological Sciences. He was elected this year a member of the Zoology Committee of the Union. Dr. Lal's main line of investigation has been helminthological, but that has not prevented him from making useful contributions in other fields of invertebrate and experimental zoology. Under his conscientious care, zoology in Lucknow should continue to flourish.

## Textile Institute

HONORARY life membership of the Textile Institute, Manchester, has been conferred on Mr. Fred Scholefield, formerly head of the Department of Textile Chemistry, Manchester College of Technology, in recognition of the long and valuable services given by him to the Institute. Mr. Scholefield has been a member of its Examinations Board for twenty-five years, being chairman of the Board in 1938, and received the Institute Medal in 1951.

The first formal lecture to be given on the Continent of Europe under the auspices of the Textile Institute will be delivered by Mr. J. R. Whinfield at the Swiss Federal Institute of Technology, Zurich, on November 25. Mr. Whinfield gave the Emsley Lecture at Institute headquarters on October 14, and will speak on the same subject at Zurich, namely, "Textiles and the Inventive Spirit".

## British Museum (Natural History): Appointments

THE Principal Trustees of the British Museum have appointed Dr. George Taylor, keeper of the Department of Botany in the British Museum (Natural History), to be a deputy chief scientific officer on the retirement of Mr. N. D. Riley, who has held that office in conjunction with the keepership of entomology; and Dr. William Edward China to be keeper of the Department of Entomology in succession to Mr. Riley.

Dr. Taylor (who will continue to be keeper of the Department of Botany) entered the Museum in 1928 after graduating with first-class honours at the University of Edinburgh. During his service in the Museum Dr. Taylor has been concerned mainly with flowering plants, and has taken part in collecting expeditions to East Africa and Tibet. Apart from his Museum work, he is a general secretary of the British Association for the Advancement of Science and president of the Botanical Society of the British Isles, and takes an active part in the affairs of the Royal Horticultural Society.

Dr. China was a scholar of Trinity Hall, Cambridge, where he graduated with second-class honours in zoology in 1920 (Sc.D., 1948). He entered the Museum in 1922 and throughout his career has specialized on the Hemiptera–Homoptera (the 'true' bugs). He has published some two hundred papers on these insects and is general editor of the World Catalogue of Hemiptera (published in the United States).

## Water Resources and Water Requirements in Britain

THE Central Advisory Water Committee has decided to institute inquiries into the growing demand for water and into the collection of information about the water resources of Britain. It appointed members to form the nucleus of two sub-committees which will report back to the main committee; they have power to co-opt, so that the inquiries will be widely representative. The terms of reference of the sub-committees are: (a) Sub-Committee on the growing demand for water (*chairman*, Alderman R. C. Yates). "To consider the extent to which the demand for water for domestic, industrial, agricultural and other purposes is increasing and is likely to increase; to consider the problems involved in meeting these demands, including, in broad terms, the cost; to consider whether there are any substantial economies in the use or cost of water which could be made without reduction in standards of hygiene or in industrial or agricultural efficiency; and to make recommendations". (b) Sub-Committee on information on water resources (*chairman*, Prof. J. Proudman). "(i) To review the current activities which contribute to our knowledge of the nation's water resources; (ii) to define the additional work needed to make a balanced survey of the quantity and quality of surface and underground water available for domestic, industrial and agricultural use; (iii) to advise on ways of collecting and interpreting the necessary information, correlating it with information from other sources and publishing it".

## Society for Visiting Scientists: Report for 1954–55

THE annual report of the Council of the Society for Visiting Scientists, presented to the eighth general meeting on September 27, welcomes an additional grant of £1,500 from the British Council, which has enabled the Society to undertake necessary repairs and improvements to its house at 5 Old Burlington Street, London, W.1. Prof. W. Wardlaw has succeeded Prof. F. J. M. Stratton as joint honorary secretary. Though a small increase has been made in the charges, the facilities offered to scientists staying at the Society's house have been considerably improved. The information service has also been extended, as well as the use made of it, and has proved useful in Britain as well as overseas for locating individual scientists or obtaining particulars of their special fields. It has been necessary, for financial reasons, to reduce to a minimum the receptions given to special groups of scientists or to distinguished individual scientists from abroad, and it has also been decided to concentrate on a limited number of discussion meetings in each session. Those held during the past session dealt with nuclear energy in industry and medicine; recent research on speech; colour from the point of view of the painter and the scientist; and current concepts of allergy. The home British membership of the Society has increased to three hundred and twenty (including sixty temporarily abroad), and the total membership exceeds two thousand five hundred. Personal contact still seems to be the most effective form of publicity for the Society.

## Publicizing the Chemical Profession

UNDER the title "Public Relations for the Chemical Profession", the American Chemical Society News Service has issued a handsome brochure, replacing the booklet "Publicizing the Chemical Profession" and the volume "The American Chemical Society News Service—Voice of the Chemical Profession", issued in 1951. The objectives of this News Service are stated to be: to increase public understanding of the meaning and importance of chemical progress; to encourage sound development of chemical science and industry, thereby promoting the welfare and security of the nation; to improve the professional, economic and community status of the chemist and chemical engineer; to enhance the public recognition and prestige of the American Chemical Society, its divisions, local sections and individual members; and to acquaint well-qualified young men and women with the nature of opportunities for careers in the chemical profession. The News Service makes full use of the press, radio, television and other media in disseminating information about the chemical profession and also co-operates closely with other organizations. The account of its activities, and perhaps particularly the use being made of broadcasting and television, should be of considerable interest to British readers concerned with the promotion of the public understanding of science. Both in the brief historical review of the development of the News Service and in the account of the work done in this field by local sections of the American Chemical Society and other agencies of the Society, the brochure contains material which is relevant and suggestive in the context of the dissemination in Britain of accurate information on scientific and technical matters generally; and the concluding remarks about the responsibilities of the individual member of the American Chemical Society apply almost equally to the scientist in general, in Britain as well as in the United States.

## Inland Fisheries Training Centre in Java

An international centre for advanced training of government officers in the development of inland fisheries and fish culture, organized by the United Nations Food and Agriculture Organization in co-operation with the Government of Indonesia and the Indo-Pacific Fisheries Council, has been opened in Java, and the first course, lasting until December 10, has been started, the participants coming from Australia, Burma, Ceylon, Hong Kong, India, Indonesia, North Borneo, Pakistan, Philippines, Sarawak and Thailand. Instruction is given at the Centre in the basic principles of limnology, the operation of small, controlled bodies of water maintained simply for fish production, and the wider field of improving fish production in natural fresh- and brackish-water areas. Methods of management such as the addition of nutrients to the waters, the control of predators and water weeds and the introduction of new species of fish are reviewed. The participants will spend about half their time attending lectures and working at the laboratory and experimental ponds of the Indonesian Inland Fisheries Service at Bogor, and the remainder of their time will be devoted to field trips throughout Java. The Food and Agriculture Organization is applying considerable efforts to the development of fish farming, and has engaged, as a short-term consultant, a senior farm-management specialist of the United States Department of Agriculture, who is at present studying the economics of fish culture in West Germany, Israel, India, Thailand and Malaya. He will lecture on his conclusions at the centre in Java. The staff for the centre has been recruited from Belgium, China, France, Holland, India, Indonesia and the United States. Indonesia has been chosen by the Organization because of the importance of inland fisheries as one of the country's primary industries. There are large areas of inland water, both fresh and brackish, swiftly flowing and still. Many of the varieties of fish are indigenous; but a number have been introduced from abroad, including most notably carp and tilapia. There is a well-developed inland fishery administration and a highly organized and competent fishery research and extension service.

## Geology of Rockall

At a meeting of the Geological Society of London at Burlington House on November 2, Dr. P. A. Sabine exhibited, on behalf of the Geological Survey and Museum, rock specimens collected on Rockall by Mr. James Fisher during the recent visit there by the Royal Navy. Dr. Sabine directed attention to the small size of the island, the visible portion of which, he pointed out, would fit inside the Geological Museum. A portion of a specimen collected in 1862, on one of the three previous landings, was also exhibited, as well as air photographs. The new specimens of rockallite, an ægirine granite, already known to be unusually rich in zirconium and cerium, are being examined by officers of the Geological Survey. Mr. James Fisher, who was present at the meeting, then gave a graphic account of the landing. The Rockall specimens are now on view to the public in the Geological Museum.

## Photoelectric Measurements at Kvistaberg Observatory, Sweden

A description of the photoelectric instrument at the Kvistaberg Observatory is given in an article by Åke Wallenquist (*Kungl. Svenska Vetenskaps-akademiens Handlingar*, Fjärde Serien, Band 5, Nr. 5; 1954), in which all the parts are very carefully explained with the aid of a number of diagrams and photographs. Kvistaberg Observatory, which forms part of the University of Upsala Observatory, is situated at Bro, Uppland, on the slope of a hill on the northern shore of an arm of Lake Mälaren, long. 17° 36·4′ E., lat. 59° 30·1′ N. The photoelectric instrument is a 41-cm. Cassegrain telescope, the primary parabolic mirror of which is of 'Pyrex' glass and was refigured at Upsala after it had arrived from the United States. The mounting of the instrument is of the German equatorial type, and the axes, which originally belonged to an old 9-in. refractor at Upsala Observatory, are made of steel and are heavy; the system of axes was modernized in the Observatory workshop and furnished with ball-bearings. Owing to rather unfavourable weather conditions at Kvistaberg for photoelectric photometry—like many other places in Sweden—differential observational programmes are generally undertaken with the object of eliminating the effects of sudden variations in the transparency of the atmosphere. For this reason, photoelectric determinations of the colours of the stars and determinations of differences in the magnitudes of the components of double stars form the main programme at the Observatory, though under good seeing conditions it is possible to carry out more absolute photometric photometry, with the determination of magnitudes of individual stars. Two colour-filters are used for the determinations of colours and magnitudes of the stars—a blue filter of type *BG* 12 and a yellow filter of type *GG* 11, supplied by Schott und Gen., Jena. The article contains a table with the final values of the $m_{pg}$ magnitudes and colours of fourteen north polar sequence stars as measured photoelectrically at Kvistaberg.

## Copals and their Botanical Origin

THE study of fresh copals of known botanical origin has shown that, with some exceptions, their discrimination by the usual characteristics is imprecise and hazardous. On the other hand, it has now been shown that the infra-red spectrographs of their extracts are characteristic and specific (L. Hellinck, *Publ. de l'Inst. Nat. pour l'Étude Agron. Congo Belge* (I.N.É.A.C.); Sér. Tech. No. 44, 1955). When the spectrographic method was applied to the study of 'fossil' copals, it was concluded that these had been produced by the same species that yield fresh copal, *Guibourtia demeusei* and *Tessmannia anomala* being the most important two in that order. It has also been confirmed that, in the course of a few months, freshly exuded copals possess the collective properties of 'fossil' copal. Hence it has not been possible to study the ageing of copal or to assign precise ages to fossil materials.

## Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: R. F. Cumpston and R. B. Royle (agricultural supervisors, Nyasaland), principal agricultural supervisors, Nyasaland; C. E. Moore (agricultural officer, Gold Coast), senior soil conservation officer, Gold Coast); J. D. Tallantire (senior agricultural officer, Federation of Nigeria), principal agricultural officer, Federation of Nigeria; I. T. Twyford (soil scientist, Fiji), chemist, Department of Agriculture, Fiji; D. H. Welch (principal agricultural officer, Western Region, Nigeria), deputy director of agriculture, Western Region, Nigeria; W. M. C. Bagshaw (assistant conservator of forests, British Guiana), deputy conservator of forests, British Guiana; J. D. Scott (specialist forest engineer, Nigeria), conservator of forests, Sierra Leone; J. L. J. Vinson (curator, Mauritius Institute), director, Mauritius Institute; A. C. Evans, assistant director (research), Tanganyika; S. Gray, senior agronomist, Uganda; C. Harkness, plant breeder (botanist), Northern Region, Nigeria; F. M. Spencer and J. V. Webdale, agricultural officers, Tanganyika; D. P. Taylor, agricultural officer, Kenya; D. D. Thornton, pasture agronomist, Uganda; P. A. Board, fisheries officer, Eastern Region, Nigeria; M. H. D. Dowell, assistant conservator of forests, Nyasaland; P. J. Fogg, assistant conservator of forests, British Honduras; P. A. Skott, assistant conservator of forests, Tanganyika; P. E. Brown and R. Halligan, geologists, Tanganyika; R. T. Gittins, field officer (geology), Uganda; B. Hitchon, geologist, Northern Rhodesia; G. Surtees, research entomologist, West African Council for Medical Research, Nigeria; J. Lamb, director, West African Cacao Research Institute, Gold Coast; K. C. Sleep, scientific officer (chemist), Tanganyika; K. Horlyck, veterinary officer, Northern Region, Nigeria.

## Announcements

THE Royal Swedish Academy of Technical Sciences (IVA) has conferred its highest mark of distinction, the IVA Grand Gold Medal, on Dr. K. H. Gustavson, of the Swedish Tanning Research Institute, Stockholm, in recognition of his pioneering contributions to the chemistry and reactivity of collagen, and for his investigations of the mechanism of tannage, pa ticularly his research on the reaction of chromiu compounds with hide protein in chrome tanning Dr. Gustavson is president of the International Unio of Leather Chemists' Societies.

SIR RAYMOND PRIESTLEY has temporarily bee appointed director of the Falkland Islands Depend encies Scientific Bureau during the absence of th permanent director, Dr. V. E. Fuchs, who is to lea the forthcoming trans-Antarctic Expedition.

DR. R. K. SCHOFIELD, head of the Chemistry Department, Rothamsted Experimental Station (*Nature* 175, 283; 1955), has been appointed reader in soi science in the Department of Agriculture, University of Oxford, in succession to Dr. E. Walter Russell who is now director of the East African Agricultur and Forestry Research Organization (*Nature*, 175 1065; 1955).

DR. D. E. TRIBE, lecturer in animal husbandry i the University of Bristol, has been appointed to a readership in the physiology of domestic animal in the University of Melbourne.

THE University of Sheffield has appointed Dr. T. R. Kaiser and R. C. Curran to be senior lecturer in physics and pathology, respectively. The following have been appointed lecturers: Dr. R. C. Cass (chemistry), Dr. T. P. H. McKellar (psychology), Dr. V. A. Phillips (metallurgy) and Dr. A. N. Stroh (physics).

DR. K. P. BISWAS, formerly superintendent of the Indian Botanic Garden (*Nature*, 176, 239; August 6, 1955) has been appointed, as from August 1, director-in-charge of Medicinal Plants Schemes in India to develop the vegetable wealth of the country. The work is being done under the auspices of the Medicinal Plants Committee of the Indian Council of Agricultural Research, Government of India, and Medicinal Plants Committee of the Government of West Bengal, of which Dr. B. C. Roy is chairman and Dr. Biswas secretary.

THE Industrial Section of the Royal Microscopical Society is arranging a symposium and exhibition on "Fibre Microscopy", to be held at the Royal Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1, on November 16 (2–9.30 p.m.). The exhibition will consist of fourteen displays from government laboratories, research associations and private firms. Further information can be obtained from the Assistant Secretary, Royal Microscopical Society, Tavistock House South, Tavistock Square, London, W.C.1.

THE National Coal Board has decided to change the titles of its Central Research Establishments: the Central Research Establishment I, at Stoke Orchard, near Cheltenham, will now be known as the Coal Research Establishment, and Central Research Establishment II, at Isleworth, as the Mining Research Establishment. The changes have been made to indicate the character of the work carried out at the two Establishments.

REFERRING to their advertisement in *Nature* of October 15, supp. p. iii, of "The Geneva Series on the Peaceful Uses of Atomic Energy", Messrs. Macmillan ask us to point out that each volume of the series will probably be priced at 55*s*. and that the subscription terms inadvertently included in the advertisement will not apply.

# IMPORTANCE OF LARVAL CHARACTERS IN CLASSIFICATION

A MEETING of Section D (Zoology) of the British Association was held at Bristol on September 5, with Prof. F. W. R. Brambell in the chair, to consider the importance of larval characters in classification. Dr. F. I. van Emden, who opened the discussion, said that in wingless insects such as the silverfish adult and larva are much alike. In winged insects this is not so, and it is clear that adult and larva must have evolved along quite different lines. It follows that neither adult nor larval characters have over-riding importance for taxonomy: theoretically they are of equal importance. Where a resting pupal stage intervenes, many characters are quite unrelated in adult and larva. Where such a stage is absent, larva and adult have often evolved in such different environments that their classification has to be based on entirely different criteria. In practice, either stage may chance to exhibit better taxonomic characters.

In most insect groups our knowledge of the larvæ is still exiguous, but a fair number of cases are already known in which the larvæ are easier to distinguish than the adults, for example, among sphingid moths, mosquitoes, *Culicoides* midges, meloid beetles; and further examples doubtless await discovery. As a rule, however, the adults show a greater degree of differentiation than the larvæ, and consequently their characters are likely to remain more important for species determination. Larval characters, on the other hand, are likely to retain greater importance for classification than for identification. Thus the major divisions of winged insects are named with reference to larval development (Exoptergota, Holometabola, etc.). Larval characters are used extensively in the classification of Diptera, Hymenoptera, Coleoptera and Aphioidea, and they are almost as important as those of the adult for subdividing Odonata and Neuroptera. Examples of changes that have been made mainly, or entirely, with reference to larval characters are: inclusion of the order Strepsiptera in the Coleoptera; removal of the Aphaniptera (fleas) from the Aptergota to a position among winged orders near the Diptera, a step first advocated by Lamarck in 1801. Since classification attempts, at least to some extent, to summarize phylogeny, it follows that larval characters have a similar part to play in phylogenetic studies. Thus acceptance of Chapman's order Zeugloptera implies agreement with the assumption that this group must have separated from the Lepidoptera sooner than did the Trichoptera. Revision of the systematic position of the Archostemata implies a revision of our ideas concerning the evolution of the coleopterous larva. At a lower level, larval characters afford clear evidence regarding the evolution of stridulating organs, armature of the teeth ventrite and other structures.

Finally, larval identification is important not only for taxonomy *per se* but also for all those branches of biology which taxonomy subserves. For example, the results of quantitative ecological research would be incomplete if larval forms had to be neglected because they could not be identified.

Dr. Isabella Gordon then discussed the systematic position of the Euphausiacea, a small but economically important group of Crustacea Malacostraca once placed with the Mysidacea in the old order 'Schizopoda'. The best-known member of the single family Euphausiidae is undoubtedly *Euphausia superba*, the krill or whalefeed. Larval development and adult structure indicate close affinity with the lower Decapoda, especially the Penaeidea, and for the past fifty years Euphausiacea has been considered an independent order of the division Eucarida coordinate with Decapoda. Some twenty years ago the late Dr. Stanley Kemp, then director of the *Discovery* Investigations, was convinced that Euphausiacea are true Decapoda related to the Sergestidae. Unfortunately his views, though fully endorsed by Calman, were never published, and Gurney (1942) was the first definitely to place Euphausiacea in the Decapoda. His suggested classification is little, if any, improvement on the old one; but his comparison of Euphausid development with that of the Penaeidea is excellent.

Most Eucarida incubate their eggs, which are attached to the abdominal pleopods; but neither Euphausiacea nor Penaeidea do this—their eggs are either shed freely or adhere for a brief period to the posterior thoracic appendages. Moreover, Euphausiacea and Penaeidea are the only Malacostraca with free nauplius larvæ. Penaeidea would appear to be more primitive than Euphausiacea; for example, there is no compression of the thoracic somites such as occurs in all other Eucarida, and the Penaeidae have elongated pear-shaped nauplii. In Euphausiacea there is extreme compression of the thorax and the appearance of the second and subsequent thoracic appendages is long delayed, except in *Euphausia superba*, which acquires precociously the swimming and feeding habits of the adult. Euphausid development, though gradual as in many Penaeidae, is remarkably close to that of the Sergestidae, where there is abrupt metamorphosis at the end of each phase. In Sergestidae also, there is the same tendency to reduction or loss of the last two pairs of thoracic appendages (post-larva, *Lucifer*) and, in some species at least, to enlargement and modification of one pair of maxillipeds. Then there is general similarity of such adult structures as the male copulatory petasma and spermatophores, the female sperm receptacle (thelycum) and the photophores. The resemblances far outweigh the differences, chief of which is that in Euphausids the gills, which are specialized podobranchs, are exposed, not concealed by the carapace—but *Lucifer* has no gills at any stage.

Calman, in a letter dated May 27, 1948, suggested making the Euphausiidea co-ordinate with Penaeidea, Caridea, etc.; Gurney was in favour of uniting the two groups with free nauplius-protozoea development in one suborder as against the rest of the Decapoda (letter dated February 12, 1949). At present the writer is undecided as to the best course to adopt. The classification of the Decapoda is a very difficult problem, and none of the schemes hitherto proposed is entirely satisfactory. (See also p. 934 of this issue of *Nature*.)

A review of recent work on larval characters in helminths by Dr. Sheila M. Willmott followed. Many helminths are highly pathogenic parasites of man and animals and, in the case of some nematodes, also of plants. All have complex life-histories including several larval stages. In the three main groups of helminths—the nematodes, trematodes and cestodes—the larvæ may show a combination of adult and larval characters. For example, in cestode larvæ the head is identical with that of the adult, but the form of the cyst is a purely larval character; in the nematodes, the gut of the larva may take the form that it shows in the adult. In the digenetic trematodes, the body of the cercaria shows such adult characters as the arrangement of the head and collar spines in the echinostomes, the absence of an œsophagus in the schistosomes and the position of the ventral sucker in the amphistomes; the tail is purely larval, although its form is frequently characteristic of the group to which the adult belongs. The character now most used in the classification of the cercariæ is the basic formula of the excretory system. This frequently resembles the arrangement found in the adult, and the fundamental flame-cell pattern forms a basis for a 'natural' classification.

Hydatid disease, which is widespread throughout the world and is more common in Great Britain than is generally realized, is caused by a larval cestode. Whether one species is responsible for the two types of hydatid disease or whether two species are involved has long been a matter of controversy. Careful investigation of the types of larvæ and the life-cycle have now led to the conclusion that two species of *Echinococcus* are involved.

Recently much work has been done on larval nematodes, particularly the Spiruroidea, with the result that a scheme of classification proposed twenty years ago and based on the morphology of the head has been confirmed. As many nematodes are free-living, it is concluded that the parasitic mode of life has been more recently acquired in this group than in the trematodes and cestodes. The degrees of adaptation of nematode larvæ to the intermediate hosts are probably better indications of phylogenetic relationships than are the relations of the adult to the definitive hosts. Four main types of larvæ are recognized: (1) the most primitive, that is, free-living larvæ; (2) larvæ developing to the third stage before hatching; (3) larvæ which develop in a vertebrate intermediate host but which act as ecto-parasites rather than as endoparasites; and (4) the most specialized, that is, those which develop in a vertebrate intermediary with a strongly marked degree of 'seclusion' within it, or which have secondarily lost the intermediate host.

The last paper was entitled "The Classification of Nematodes parasitizing Horses, using Larval Characters". Mr. D. Poynter said that to-day the horse commonly harbours large numbers of various species of nematodes, and these are often the cause of retardation in growth, illness and sometimes death. The effects of parasitism have undoubtedly been aggravated by domestication. The typical horse nematode lives as an adult in the intestines of its host and lays eggs which are passed out, with the fæces, on to the pasture. The eggs hatch and give rise to third-stage infective larvæ which live on the herbage and are ingested by the host. Equine nematode parasites all belong to the superfamily Strongyloidea; but the eggs of the various genera and species are indistinguishable from each other. Since the adults are inaccessible within the host, it is essential to obtain the free-living larval stages, and this is done by means of a special culture technique. After seven days at 28° C. in a fæces–charcoal culture, development has proceeded as far as the third-stage larvæ, which have definite diagnostic character These larvæ have been described for some of th genera and species, and a key published in 194 facilitates the determination of the larvæ obtaine from equine fæces. Unfortunately, this key is no illustrated. But a plate has now been prepare showing the various larvæ drawn to the same scal It is possible, therefore, by identifying the larvæ in given culture, to obtain knowledge of the types nematodes in the host. A survey has been under-taken using many horses, and information has bee obtained as to the incidence of the different nematode in hosts of different ages.

This culture procedure has also an importan practical application. Parasites of the famil Strongylidae are all affected to some extent b phenothiazine, a common anthelmintic which has n effect on *Trichostrongylus axei*. For this parasite copper sulphate and nicotine must be used. An rational treatment, therefore, must include a prio determination of the larvæ. A careful comparison o larval cultures obtained before and after dosing wil indicate the effectiveness of a new anthelminti against the different nematode species. For example when testing the efficiency of piperazine adipate, i was noted that every adult horse dosed showed an immediate and sharp rise in the number of eggs o *Strongylus edentatus* being passed. Subsequent critica tests proved the compound to be only 0–6 per cen effective against this species.

The general discussion which followed not unnaturally centred around the insects. Prof. G. C. Varley emphasized the practical importance to the ecologist of correlating observations on the behaviour of the adults with their life-histories, giving examples from his work on parasitic Hymenoptera. Mr. P. F. Mattingly referred to recent immunological work on mosquito taxonomy, the discovery in mosquitoes of some of the evolutionary anomalies discussed by de Beer in his book "Embryos and Ancestors", and Wigglesworth's recent brilliant exposition of the concept of insect metamorphosis as a special case of the more general phenomenon of polymorphism. He also stressed the need for comparative genetical studies on the inheritance of adult and larval characters.

ISABELLA GORDON

# INSTITUTE OF PHYSICS

## REPORT FOR 1954

THE thirty-fifth annual report of the Board of the Institute of Physics*, covering the work of the Institute during 1954, was presented to the annual general meeting of the Institute, held at the Institute's house in London on May 17. The report records that the membership in the several grades of the Institute continues to mount steadily, and the total membership has increased by 154 to 4,749. The newly established examination for entry to the graduateship grade of membership of the Institute was held during June 21–25 at centres in London, Birmingham and Paisley, and nineteen of the fifty-four candidates were successful. The numbers of candidates for the final examinations for National Certificates in Applied Physics were 206 for the Ordinary level and 75 for the Higher Certificate, compared with 151 and 55, respectively, in 1953. A one-day conference, consisting of representatives of teachers in technical colleges offering courses for National Certificates in Applied Physics, the Institute, the Joint Committee for National Certificates in Applied Physics, and industry, was held on April 12, 1954, and eight papers were read.

---

* Thirty-fifth Annual Report of the Board of the Institute of Physics, 1954. Pp. 25. (London: Institute of Physics, 1955.)

About half the total work of the Institute is now occupied by the production and distribution of its publications. The Institute publishes two monthly journals, the *Journal of Scientific Instruments* and the *British Journal of Applied Physics*, and, in addition, a monthly *Bulletin* which is circulated to members only. For the 1954 volume of the *Bulletin*, an entirely new format was introduced, its contents consisting of twenty articles, either invited contributions or based on lectures given to the Education Group of the Institute, and Institute news. A new edition of the pamphlet entitled "The Scientific Education of Physicists", giving up-to-date information regarding institutions where physics may be studied, and a revised edition of the thirty-two page pamphlet, "Notes on the Preparation of Contributions to the Institute's Journals and Other Publications", were issued during the year. A third selection of 'Laboratory and Workshop Notes" from the *Journal of Scientific Instruments* was compiled and edited by Dr. Ruth Lang and published in book form.

The report states that the Institute has continued to take an active part in discussions on higher technological education, but has not departed from its original view expressed in its 1948 report on this subject. For the second year in succession an inquiry was addressed to all new graduates in physics of the universities in Great Britain to obtain information as to their present occupations, or, where appropriate, the source of any maintenance grant. The survey is to be continued during the next few years so as to determine how, and to what extent, the services of physics graduates are being utilized. Reports were received during the year that there were several vacancies for undergraduates in physics departments in some universities and large technical colleges, and the Board's inquiries on this subject are to be issued shortly.

Details of the activities of the sixteen local branches and specialist subject groups of the Institute are listed in the report. The Australian Branch, with 415 members and four separate divisions in New South Wales, Queensland, South Australia and Victoria, respectively, held thirty-two meetings. Dr. A. C. Menzies and Prof. J. H. Bhabha visited the Victoria Division and delivered addresses, and this Division also held an exhibition of scientific apparatus in March and a conference on the teaching of physics in August. Joint meetings were held by the Electronics Group of the Institute with the Manchester and District Branch in Manchester and with the South Wales Branch in Swansea, and two conferences were also organized: the first, on luminescence, was held in April at the Cavendish Laboratory, Cambridge, and the second, on fluctuations and the limits of measurement, in September at the Institute's house in London. The proceedings of the former conference have since been published (*Brit. J. App. Phys.*, 6, Supp. 4; 1955). Following discussions with the Physical Society, a joint committee for electron physics was set up to co-ordinate activities of the two bodies in the field of electron physics, defined as "the physics of the free electron and phenomena associated with it". The Electron Microscopy Group was host to an international conference of the recently established Joint Commission on Electron Microscopy, which was held during July 16–21 in London and attended by about four hundred people; the X-ray Analysis Group held its spring conference in Cambridge on the subject of "New Developments in Structure Analysis" and its autumn conference in London on "Structure of Metals". Also, in addition to the specialist conferences held by its branches and groups, the Institute held a conference on "The Physics of Particle Size Analysis" in the University of Nottingham during April 6–9. Thirty-three papers were presented and discussed, and the proceedings have been published (*Brit. J. App. Phys.*, 5, Supp. 3; 1954).

At the general meeting of the Institute, the following were elected to take office on October 1: *President*, Sir John Cockcroft; *Vice-President*, Dr. W. H. Taylor; *Honorary Treasurer*, Dr. S. Whitehead; *Honorary Secretary*, Dr. B. P. Dudding; *New Ordinary Members of the Board*, Dr. M. R. Hopkins, Dr. J. M. A. Lenihan and Dr. J. Taylor. In addition, Prof. W. E. Curtis and Dr. C. Sykes (*past-presidents*), Mr. O. W. Humphreys, Mr. G. R. Noakes and Prof. F. A. Vick (*vice-presidents*), and Dr. H. Barrell, Dr. P. H. S. Henry, Dr. K. A. G. Mendelssohn, Mr. A. T. Pickles and Mr. H. P. Rooksby continue to serve on the Board.

# IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, LONDON

IN his inaugural address for the new session of the Imperial College of Science and Technology, London, the rector, Dr. R. P. Linstead, after reviewing briefly the history of the College, referred in some detail to certain aspects of the expansion which is planned to bring the total number of students to three thousand by 1962 without sacrifice in quality. The College is already, Dr. Linstead stated, the largest postgraduate college in Great Britain, providing in technology about one in nine of those trained in the country, while the proportion of higher degrees to total degrees is nearly 40 per cent. New senior posts at the level of professor or reader have already been or are being established in soil mechanics, statistics, instrument technology, applied geophysics, aeronautical structures, applied science, biochemistry, inorganic chemistry, light electrical engineering, parasitology, physical metallurgy, applied geochemistry, nuclear power and other subjects; but it is not intended to multiply new departments. The latest demands all call for sound fundamental training in mathematics and in the basic sciences or the main divisions of engineering, and to meet this demand the academic staff has already been increased by more than a third. At the same time, the College is providing, from its old students and staff, men and women for senior academic appointments elsewhere.

Dr. Linstead anticipates no difficulty in finding sufficient undergraduate students: he thinks that the danger of a breakdown in school science teaching had been exaggerated and is being removed, and that the post-war bulge in the school population will of itself more than meet the 17 per cent increase in annual intake of undergraduates required to maintain a total of three thousand students (including about sixteen hundred undergraduates). The College is concerned, however, to improve selection and to make the best possible use of the students who have been selected, so as to reduce the present wastage; about a hundred of the present intake of five hundred freshmen fail to go forward to the second year. In this connexion, Dr. Linstead said the College hopes soon to reintroduce an optional preliminary year which would not demand a knowledge of science and would thus provide a special means of access for the gifted non-scientist. This scheme is related to one invented by Sir Henry Tizard during his rectorship, but the majority of the first-year entry would continue to have had a sound science training at school.

Last year there were 631 full-time postgraduate students, or rather more than a third of the total, and it is intended to raise this proportion to 45 per cent. Most of the postgraduate students are taking advanced courses designed to train technologists of the highest quality. Postgraduate research is a first charge on the College, and Dr. Linstead stressed the proportion of postgraduates from overseas—at present about three hundred from forty-nine centres, mainly in the Commonwealth. Nearly two hundred of the postgraduate students came from posts in industry and in government, and in this connexion Dr. Linstead is less confident about maintaining the supply of postgraduate students, unless maintenance support is forthcoming on an adequate scale.

The College aims to produce engineers and scientists who are at the same time well-educated men and women, and Dr. Linstead thinks that this is being achieved. As regards residence, however, the College is in the worst position of all major colleges or universities in Great Britain, only 8 per cent of its students during 1953–54 being residential. It is proposed to increase this to 16 per cent, or about five hundred students, by the end of the expansion period and also to provide general amenities for all its students on the lines of what is commonly called the Ashby plan. In his address, Dr. Linstead made no specific statement on the building plans, but expressed the opinion that the decisions taken in 1953 were wise and also paid tribute to the co-operation of all concerned, not least of the 1851 Commissioners.

---

# ONTARIO RESEARCH FOUNDATION

## REPORT FOR 1954

IN his annual report for 1954 to the chairman and governors of the Ontario Research Foundation*, the director of research, Dr. H. B. Speakman, notes that, in spite of a recession in some branches of industry, there was no marked reduction in the demands made on the Foundation but rather an increase in developmental work. The Biochemistry Department was very active, work under the Rice Mills Fellowship centring largely on the development of a new milling principle designed to reduce drastically the amount of broken rice that is normal with present equipment. In the utilization of municipal waste, progress has been made in partial conversion into sugars such as xylose and certain volatile organic acids. In a fundamental study of the continuous production of protein by fermentation of yeast, it has been established that there is practically no waste of sugar and that a higher percentage yield of yea on the sugar consumed is obtained by feeding sug at low rather than at higher concentrations. Th basic study of the deterioration in flavour of edib oils continued, and substantial progress was made i the group fellowship working on the evaluation o new tanning materials.

In the Department of Chemistry, the balanc between basic research, long-term sponsored fellowship projects and short-term investigations submitte by smaller industrial units is emphasized. Filte paper chromatographic techniques have demonstrated that normal sodium phosphate glasses, rapidl quenched from the molten state and dissolved i water, show only linear polymers with a reproducibl distribution of molecular weight, depending only o the sodium/phosphorus ratio, and the technique ha been improved so that small amounts of ring o linear polymers can be determined in the presence o large amounts of the other kind. Two surveys of ai pollution, at Maitland and Millhaven, were concluded, and the laboratory is developing new apparatus and methods for the accurate determination of air contaminants. A study of the productio of grafted polymers continued, and one of method for the production of alkyd resins has indicated tha straight-chain alkane sulphonic acids may be suitabl catalysts in the condensation. Definite progress i reported in the study of the chemistry of wast sulphite liquors; a number of lignin compounds hav been examined as dispersing agents for use in drillin oil-wells, while others may be useful in treatin boiler feed water to prevent scaling, and a condensat of lignin and phenolic compounds was found t possess tanning properties.

In the Department of Engineering and Metallurgy investigations on the production and properties o steel of controlled density have led to strikin improvements in the product, and the study of th causes and the detection of faults in wire ropes has le to some progress in the design of an instrument which can be used at the mines under operating conditions

The Department of Parasitology continued its work on tapeworms found in carnivorous animal as well as a survey of animals infected with th larval or adult forms of the parasites. Work on flie of the genus *Protocalliphora* continued, as well a the investigation of the filariid nematodes in birds and the extensive researches on two species of fluke of the genus *Alaria*, occurring in foxes, are almos complete. Further data on the epizootiology, transmission and development of *Leucocytozoon* in duck confirmed the conclusion that asexual parasites occur in the blood of infected ducks during their cycle o development.

The Department of Physiography finished the mapping between North Bay and Sault Ste. Marie and made differential thermal and X-ray analyses on the clay, less than 1 micron in diameter, from all main types of glacial till in southern Ontario. A new installation for evapo-transpiration studies was set up at Kapuskasing Experimental Station, and an unbroken daily record was secured for the summer months; a study of soybean growth and development was commenced on five varieties with a range of maturity.

In the Textiles Department, besides research on nylon, the optimum temperature at which fabrics from different synthetic fibres can be ironed has been studied, as well as factors affecting the photochemical degradation of viscose rayon.

# THE STRUCTURE OF COLLAGEN

By Dr. ALEXANDER RICH* and Dr. F. H. C. CRICK

Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems,
Cavendish Laboratory, Cambridge

VERY recently, Ramachandran and Kartha[1] have made an important contribution by proposing a coiled-coil structure for collagen. We believe this idea to be basically correct but the actual structure suggested by them to be wrong.

Their structure consists of three polypeptide chains, each having approximately a three-fold screw axis. In addition, the chains slowly wind around each other to form a coiled coil, thus reproducing the observed non-integer screw axis[2]. The major helix is right-handed, the minor one left-handed. Each chain is held to its neighbours by *two* sets of systematic hydrogen bonds.

The allowed sequence of residues is

—*G*—*R*—*P*—*G*—*R*—*P*—, etc.,

where *G* implies glycine only, *R* implies any residue except proline or hydroxyproline, and *P* implies any residue, but usually proline or hydroxyproline.

We believe this structure to be wrong for two reasons. (1) It is stereochemically unsatisfactory. In particular, there is a very short $C_\alpha$—$C_\alpha$ contact of 3·3 A. (normally 3·6–4·0 A.) and an extremely short $C_\alpha$—O contact of 2·6 A. (normally 3·2–3·5 A.). In addition, the hydrogen bond angles are on the outside limit of the values usually found. (2) It is not compatible with recent work[3] on the amino-acid sequence, which shows that

—gly—pro—hypro—

is a common sequence in collagen.

On the other hand, Dr. Pauline Cowan and her co-workers[4] have informed us that a preliminary optical diffraction pattern of this structure agrees qualitatively with the observed wide-angle X-ray pattern of collagen. They have also pointed out to us that the configuration of the backbone of the polypeptide chain is similar to that found by them for polyproline[5]. These facts suggest that the structure, though incorrect, is on the right general lines.

Our own work on collagen has sprung from our recent structure for polyglycine II[6]. We have taken a compact group of three adjacent chains out of the polyglycine lattice (space group $P\,3_1$) and twisted them, as in the Ramachandran–Kartha structure, to form a similar coiled coil. Such a group can be selected in two different ways, since the symmetry is trigonal, not hexagonal. We have called the two resulting arrangements structure I and structure II. Both have a right-handed major helix and a left-handed minor helix, arranged to fit the observed non-integer screw. Both have only one set of systematic hydrogen bonds linking neighbouring chains. In structure I the NH-groups point anticlockwise when viewed from the carboxyl ends of the chains; in structure II clockwise.

These two structures are thus similar to that of Ramachandran and Kartha in being three-chain coiled-coil structures; but they differ in having only one set of systematic hydrogen bonds instead of two. Moreover, they are both stereochemically completely satisfactory.

Both structure I and structure II will accommodate the sequence

—gly—pro—hypro—

but they do so in a different manner. In structure II the glycine position is near the axis, and every third residue must be glycine. The proline and hydroxyproline positions, on the other hand, are far removed from the axis. Either proline or hydroxyproline can go into either position—there seems to be no preference—and in neither case can the OH of hydroxyproline make a hydrogen bond with a CO group of an adjacent chain within the same set of three chains.

Structure I will also accommodate the above sequence; but when the hydroxyproline is in the expected position (that is, previous to glycine) its OH group can form a hydrogen bond to one of the adjacent chains within the same set. Careful structure building has shown that not all the possible positions for hydroxyproline can be occupied if the structure is to fit together comfortably. This is compatible with the amino-acid analyses of collagen, which show that the amount of hydroxyproline present in bovine collagen[7] would fill about one-third of these sites. The polypeptide backbones, being held together by only one set of hydrogen bonds, have a certain amount of flexibility. In the undeformed structure, only glycine can be accommodated in the glycine sites. However, if the structure is deformed somewhat, these sites can accommodate other residues, though only to a limited extent. This may explain certain minor features of the amino-acid sequence data.

We have made an exhaustive study of all possible structures (using topological enumeration, similar to that of Bragg, Kendrew and Perutz[8]) of this general type which are compatible with the observed screw axis—that is, with three parallel chains linked by at least one systematic set of hydrogen bonds—and we find that: (1) no structure with *two* systematic sets of hydrogen bonds is stereochemically possible; (2) no other structure with *one* systematic set of hydrogen bonds is stereochemically satisfactory except the two described above derived from polyglycine. Neither were we able to add occasional backbone hydrogen bonds to structures I and II in a convincing manner.

All the above findings are independent of arguments about the side-chain arrangements. We therefore conclude that structures I and II, though making few hydrogen bonds systematically, are the best that can be achieved along these lines. Note that, as in polyglycine II[6], it is not impossible that the direction of one of the three chains may be reversed.

Preliminary work on the optical transforms of these two structures (carried out with Dr. A. Elliott on his optical transform machine) show both structures to give rough agreement with the X-ray pattern, though structure II shows a discrepancy on the fourth layer-line. Both structures are also compatible with the infra-red[9] observations. Further work will therefore be required to decide between them. We are at the moment inclined to favour structure I, because it makes effective and systematic use of the hydroxyproline residues. Gustavson[10] has presented extensive evidence suggesting that this unusual amino-acid stabilizes the collagen structure. We feel that this is more likely to take place by formation of hydrogen bonds within a group of three chains than between different groups of chains[1]. In addition, structure I explains in a natural way the amino-acid sequence data. Thus while the peptide hypro—gly is common, gly—hypro is not found. Similarly, gly—pro is common, whereas pro—gly is rare. In structure I this preference is explained in terms of the hydroxyproline-hydrogen bond between the chains.

---

* Permanent address: Physical Chemistry Section, National Institute of Mental Health, Bethesda, Maryland.

Although we cannot at the moment make a final decision between the two structures, we think it very probable that one of them is correct (or, less likely, both). The general agreement with the X-ray pattern, the close resemblance to polyproline and to polyglycine II, and the ability to explain the major features of the amino-acid sequence data all suggest that collagen is a structure of this type; that is, a three-chain, coiled-coil structure, with one set of systematic hydrogen bonds.

Full details of our findings together with co-ordinates of both structures will be presented elsewhere.

We should like to thank Dr. A. Elliott for hi assistance in obtaining the optical transforms.

# LANGMUIR'S PARADOX

By DR. D. GABOR, DR. E. A. ASH and D. DRACOTT

Department of Electrical Engineering, Imperial College of Science and Technology, London

A LITTLE more than thirty years ago, Irving Langmuir and Harold Mott-Smith carried out an important series of investigations on low-pressure mercury discharges[1], on which they based their theory of the positive column in electro-positive gases. They distinguished two regions in the discharge: the almost neutral arc plasma, and the thin boundary sheath which separates it from the tube wall. In the plasma the motion of the ions is regular and mostly radial, whereas the electron motion consists of a regular longitudinal drift, with a superimposed random, Maxwellian component. The random motion corresponds to 'electron temperatures' of the order of several 10,000 deg., many times higher than the gas temperature. The boundary sheath enables the plasma to remain neutral, by maintaining a potential well of such depth that most of the electrons are repelled, and only a small fraction reaches the wall, together with an equal number of positive ions.

This theory was highly successful in all respects except one; but this exception, as Langmuir showed in a number of important papers[2,3], presented one of the worst discrepancies known in science. Once the existence of electron temperatures was accepted, the theory of Langmuir and Mott-Smith could account for all observations, but this phenomenon itself remained not only unexplained but also inexplicable. Maxwellian energy distributions have been observed, in discharge tubes of a few centimetres in diameter, at mercury pressures so low that the mean free path was several times the tube diameter; and, moreover, at such small electron densities that it would take an electron, in the average, a path of the order of 10 m. to exchange amounts of the order of the mean energy with other electrons. The tube wall eliminates all the time electrons above a certain energy limit, and an electron collides, on the average, some thousand times with the boundary sheath before it has a chance to pick up energies of this order. Yet probe measurements fail to reveal any deficit of fast electrons among those returning from the wall, even at a distance of only a few millimetres from it.

Though the existence of electron temperatures has become a well-established part of our knowledge of low-pressure discharges, the fact that this phenomenon persists in a region in which it has theoretically no right to exist appears to have been largely ignored, in spite of Langmuir's emphasis. Our investigations, which started five years ago, have now led to the elucidation of what we propose to call 'Langmuir's paradox'.

The first step was to clear up the question whether the discrepancy between theory and experiment could not be ascribed to faulty theory. Interaction between electric charges in plasmas is very complicated, as the Coulomb forces extend appreciably over spheres containing thousands of other charges; hence there was some reason to distrust the simple theories which considered short-distance interaction between pairs of electrons only. But experiments by two of us (E. A. A. and D. G.[4]) have shown that the scattering and energy exchange of electrons in plasmas and in electron clouds in thermal equilibrium, with densities of the order as they occur in low-pressure discharges, exceed the predictions of the theory based on binary collisions at most by a factor of 2–5. The rather large margin of uncertainty is due to the smallness of the interaction, which makes the measurements very delicate. A theory afterwards developed by one of us (D. G.[5]) indicates that the collective interaction which is neglected in the binary collision theory amounts in fact to a correction of a few per cent only. Thus the mechanism responsible for Langmuir's paradox must arise in some way from the fact that the discharge plasma is not

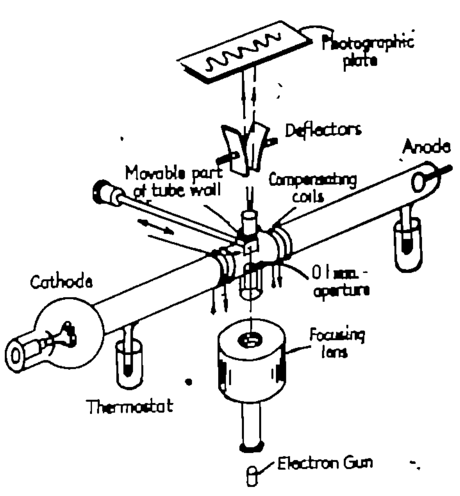

Fig. 1. Apparatus for the measurement and oscillography of plasma-boundary oscillations in a low-pressure mercury arc

in thermal equilibrium, and we started a search for organized oscillations.

Several devices were used in turn in this search, but they mostly had in common the use of electron beam probes for the exploration of the discharge. The principle of the method is illustrated in Fig. 1. A long d.c. mercury arc is maintained in a discharge tube, from which all residual gases are eliminated, while the mercury pressure is maintained by saturation in several carefully temperature-controlled side arms. (The pressures investigated were in the range 0·5–3 microns.) A finely collimated electron beam of 1–20 kV. is shot at right angles through the discharge. It is limited to about 0·1 mm. diameter by an aperture at the entry side, while at the exit side the aperture is made large enough to pass a slightly deflected beam. By pumping vigorously at both sides it was assured that the electrons suffer no collisions except in the discharge space. A section of the wall of the discharge tube, about 2 cm. square, was made movable so that the beam could pass outside or inside the boundary sheath. So long as it passed outside the sheath, that is to say, through the arc plasma, it was found that the beam was neither deflected nor appreciably diffused, which proved the absence of significant oscillatory fields in the plasma.

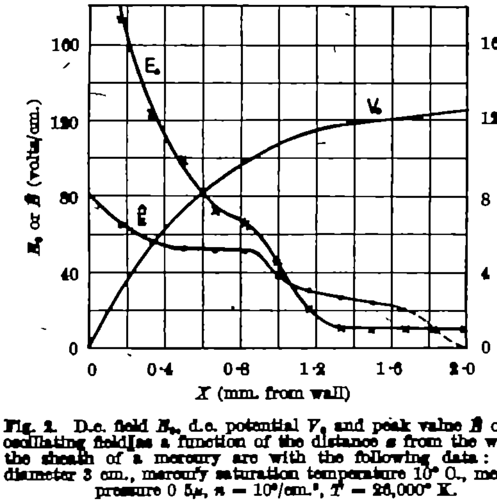

Fig. 2. D.c. field $E_0$, d.c. potential $V_0$ and peak value $\hat{E}$ of the oscillating field as a function of the distance $x$ from the wall in the sheath of a mercury arc with the following data: tube diameter 3 cm., mercury saturation temperature 10° C., mercury pressure 0·5μ, $n = 10^9$/cm.$^3$, $T = 26,000$° K.

On the other hand, when the electron probe passed through the boundary sheath, which in these experiments was 1–2 mm. thick, it was deflected and appeared diffused, but only in the direction at right angles to the wall. The mean deflecting field was measured by compensating the deflexion locally by a weak magnetic field parallel to the wall. This ensured that the beam passed at a constant distance $x$ from the wall, and enabled us to plot the d.c. field-intensity $E_0$ as a function of $x$. An example of such measurements is shown in Fig. 2. From the field $E_0$ it was possible to plot the d.c. potential profile $V_0(x)$ in the sheath, which corresponded approximately if not exactly to that calculated from the theories of Langmuir and Mott-Smith and Langmuir and Tonks.

After eliminating the static deflexion, the cathode-ray spot retained its elongated shape, which could scarcely be interpreted otherwise than as revealing the presence of an oscillating field, with a peak value $\hat{E}$, which is also plotted in Fig. 2 as a function of $x$. These observations were made in 1951 (E. A. A.[6]); but all attempts to prove the correctness of this interpretation failed until the end of 1954. It appeared an evident suggestion to detect the oscillations by passing the electron beam through a slit at right angles to the deflexion, catching it in a collector, and amplifying the oscillatory current. However, all that could be detected in this way was a low-frequency component in the oscillations, extending up to about 100 kc./sec., which could account only for a small fraction of the amplitude inferred from the deflexion. In the high-frequency region, which we explored up to 600 Mc./sec., it was impossible to detect any signal above the noise-level of the amplifiers, owing to the poor matching of the electron beam to ultra-high-frequency broad-band devices.

It was finally decided to try recording the oscillations directly on a photographic plate. This, as we realized beforehand and confirmed later, was an undertaking with only a marginal hope of success, because the exploring electron beam had to be kept very narrow (0·1 mm.) and was therefore very weak, with a current of about 0·1 μamp. The energy could not well be raised beyond 20 keV. if the deflexion sensitivity was to be kept at a reasonable level. A compromise was struck, at which the deflexion amplitude was a few spot diameters, and a record could just be obtained with the most sensitive plates available at sweep speeds of about $10^8$ cm./sec. Thus we succeeded at last in demonstrating the existence of very-high-frequency oscillations in the boundary sheath, at least in arcs at 0·5–1μ pressure, where conditions are most favourable.

Some of the results are shown in Fig. 3. These oscillograms were taken in arcs with an electron concentration of $n = 3 \times 10^9$, electron temperature $T = 26,000$°. It is seen that in this case the phenomenon consists of a very-high-frequency oscillation of 100–120 Mc./sec., modulated by a noise-like band in the range 10–100 kc./sec. The first two oscillograms (Fig. 3a) show the envelope of the oscillation, as it appears on a long time-base; the irregular character of the modulation is well in evidence. Fig. 3b shows the very-high-frequency oscillation at maximum sweep-speed. The wave-form is not quite sinusoidal; its basic frequency is about 100 Mc./sec., which is not quite constant. It differed by about 20 per cent in oscillograms taken in rapid succession, but it is evident that the frequency is more nearly a constant than the amplitude.

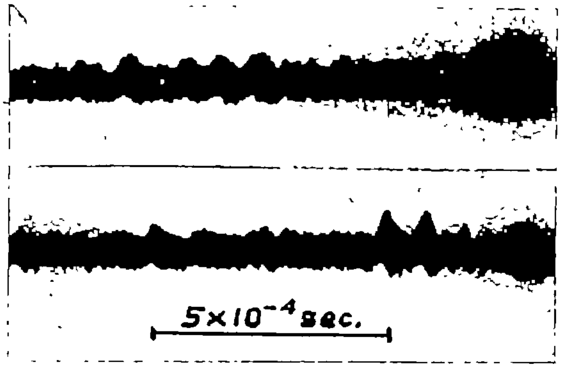

Fig. 3a. Two records of plasma-boundary oscillations on a long time-scale, showing the irregular character of the envelope

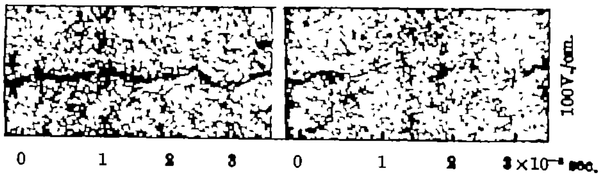

Fig. 3b Two records of plasma-boundary oscillations on a very short time-scale, showing the basic frequency of about 100 Mc./sec.

In the gas-discharge field, it is often more expedient to ask first about the purpose of a phenomenon rather than for its causes. Gas discharges strike us as highly viable phenomena. In particular, it has been often remarked that the plasma tries to occupy as much of the discharge space as possible, and to secure its survival by a remarkable variety of mechanisms. For its survival the plasma of the positive column requires a certain small proportion of fast electrons, to replace by ionization the ion pairs lost at the wall. We see now that at pressures and at electron concentrations which are too low to produce the fast 'Maxwellian tail' by collisions, this is produced by interaction with the oscillating boundary sheath. The frequency of these oscillations is such that an electron diving into the sheath and emerging from it will spend just about a full cycle in it. This can be seen by approximating the part of the $V_s(x)$ curve near the sheath edge, which contains the major part of the electrons, by a parabola. It is well known that electrons in a parabolic potential trough oscillate with a frequency which is independent of their energy. In the case shown in Fig. 2, this works out to about 60 Mc. Hence during the time in which the electron dives into the sheath and returns again into the plasma, that is to say, performs one half-cycle of oscillation in the parabolic trough, the very-high-frequency field of 100–120 Mc./sec. goes nearly through a full cycle. Thus an electron diving into the sheath in the appropriate phase will gain energy both ways, and it can be seen from the data in Fig. 2 that this gain will be of the order of several electron volts. These electrons form the fast 'Maxwellian tail'. Their gain is balanced by the loss which other electrons suffer—those which dive into the sheath in the opposite phase. On balance, the electrons must lose a little energy to the oscillating sheath, because a certain amount of power is required to cover the losses; these, however, are very small because the boundary sheath is a resonator with small damping. As the oscillations are longitudinal, they do not radiate outwards, into the glass or metal envelope, nor are they propagated inwards, into the plasma, because their frequency is well below the critic plasma frequency ($f_p = 9{,}000\, n^{1/2}$). In the case show in Fig. 3, the electron concentration was $n = 3 \times$ $10^9$/cm.$^3$; hence the plasma frequency was $f_p =$ 500 Mc./sec. Thus the plasma-boundary frequenc and its harmonics up to the fourth or fifth were we below it. Some losses are bound to arise, thoug by the imperfect coherence of the boundary oscillations, that is to say, by their not vibrating in the sam phase over large areas of the envelope.

Thus the oscillating boundary sheath is a ver efficient energy exchanger, and there are good reason for believing that it is this mechanism which maintain all low-pressure arcs in mercury and in other electropositive gases until the collision mechanism take over. The experimental evidence regarding the poin where the change-over takes place is not yet conclusive. Fig. 4 is a record of the various discharg data, $n$, $T$, the gradient $G$ and the oscillating pea intensity $\hat{E}$, over a pressure range 0·5–3μ in mercury It is seen that $\hat{E}$ falls gradually and becomes zer at the upper end of the pressure-range. This, however we suggest interpreting as the failure of the electro-probe method rather than a real fade-out of th boundary oscillations. In all our experiments th length of the movable wall was 2 cm., and it is ver likely that, at the higher concentrations, and consequently thinner sheaths and higher frequencies, th boundary oscillations were no longer coherent ove this length. In all probability they persist up t appreciably higher pressures and concentrations than those recorded in Fig. 4.

Turning now from the teleological to the causal interpretation of these oscillations, they appear to be of the 'reflex klystron' type, that is to say, they maintain themselves by the slight energy given up in the mean to the oscillating sheath by the returning electrons. (One could think that this energy is perhaps supplied by a slowing-down in the mean of the electrons which reach the wall, but we have found that the oscillations persist unaltered if the wall is made so strongly negative that not one electron in a million can reach it.) It is not so easy, though, to account for the remarkable fact that, unlike man-made klystrons which operate with

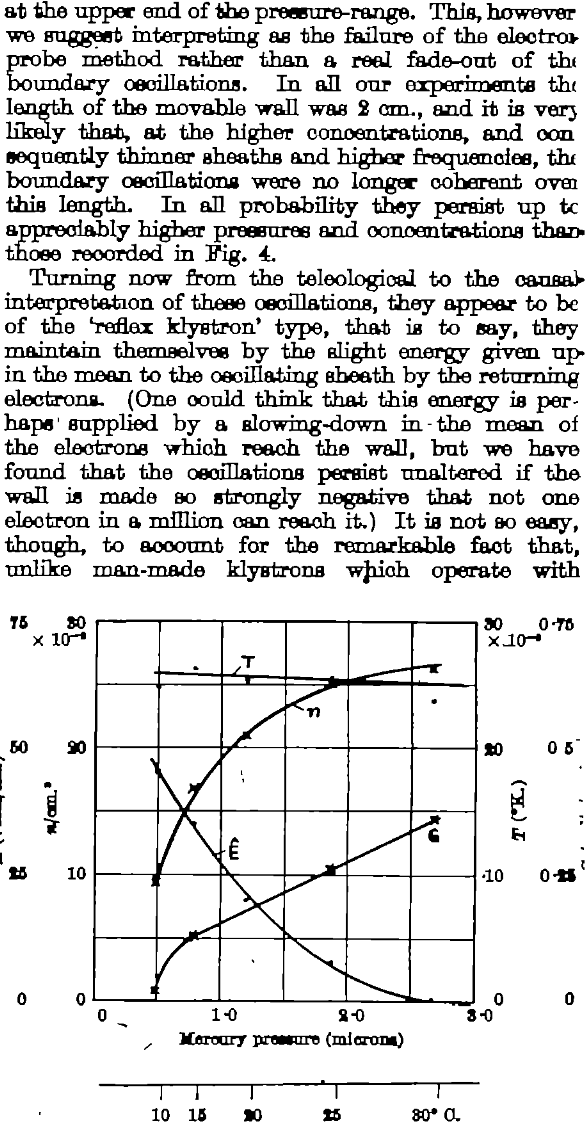

Fig. 4. Electron concentration n, electron temperature T, gradient G and oscillating peak field-intensity $\hat{E}$ in a mercury arc with 100 m.amp. current, at various pressures

electrons of almost uniform energy, this oscillator operates so extremely near a thermal equilibrium that it is not easy to distinguish the electron energy distribution from the Maxwellian. In fact, the high-energy tail is so nearly Maxwellian that it cannot account for the oscillations; we attribute these to the small deficiency in slow electrons which we have regularly observed in probe measurements.

Though a detailed theory of this highly complicated and non-linear process is still being sought, its outlines are clear enough for venturing a generalization which may serve as a heuristic guide in searching for new phenomena: plasma-boundary oscillations are likely to arise at almost any boundary, not necessarily abrupt or permanent, which is in contact with a plasma however slightly off equilibrium. These oscillations constitute a powerful mixing, entropy-increasing mechanism, and as a by-product they might produce some radiation in all but cases of exceptional symmetry or regularity. What part, if any, they play in the generation of cosmic radio noise phenomena it is as yet too early to say.

# EFFECTS OF GAMMA-RAYS ON SOLUTIONS OF SODIUM DEOXYRIBONUCLEATE

## POSSIBLE CHEMICAL MECHANISM FOR THEIR BIOLOGICAL EFFECTS

By R. A. COX, DR. W. G. OVEREND*, DR. A. R. PEACOCKE and S. WILSON
Department of Chemistry, The University, Birmingham 15

IT is well established that degradation of aqueous solutions of sodium deoxyribonucleate by ionizing radiations is an indirect effect due to radicals ($OH^{\bullet}$ and $HO_2^{\bullet}$, in the presence of oxygen) formed by the breakdown of water[1–4]. Such radiations cause a decrease in the molecular weight[5] of the deoxyribonucleate with a consequent drop in the viscosity of the solutions. Previous viscosity studies[1,6–8] have been mainly confined to measurements of specific viscosity ($\eta_{sp}$) at one concentration and, over a limited range, log $\eta_{sp}$ has often appeared to be a decreasing linear function of dosage[1,4]. From this it has been inferred[4] that the radicals attack the products of degradation; but strictly speaking it is only changes in the intrinsic viscosity $[\eta]$ ($=(\eta_{sp}/c)_{c\to 0}$) which are of significance in the estimation of molecular size and shape. Charlesby[9] has shown that such changes in $[\eta]$ can be related to characteristics of both the radiation process and of the polymer irradiated. The aim of the investigation now reported was twofold: to measure the intrinsic viscosity $[\eta]$ of deoxyribonucleate degraded by γ-rays in order to apply these theoretical considerations[9]; and to study more closely the chemical effects of dosages lower than those which previous workers[10–12] have shown to disrupt the constituent nucleotides of the deoxyribonucleate. There appears to be little knowledge concerning changes in this dose-range which is likely to be biologically more important. The latter problem was investigated by titration and other techniques. Titration studies are of particular value[13,14] in following the disappearance of the specific hydrogen bonds which cross-link the two constituent helices of sodium deoxyribonucleate in the solid state[15] and in solution[14].

Sodium deoxyribonucleate was prepared from herring sperm by water extraction of soft roes, and protein was completely removed from a saline solution (1 *M* sodium chloride) of the nucleoprotein by means of sodium dodecyl sulphate[16] followed by the method of Sevag[17]. Aqueous solutions of deoxyribonucleate (20 ml., 0·17–0·43 per cent) were subjected under standardized conditions to the radiation from a 100-curie cobalt-60 source (γ-rays, 1·25 MeV). After the irradiation, sodium chloride was added (to 0·1 *M* sodium chloride) and the solution left at 0° C. for a period sufficiently long (usually 24–30 hr.) for most of the 'after-effect'[1,6,7,8] on the viscosity to be complete. The flow times of this deoxyribonucleate solution in an Ubbelohde[18] viscometer were then measured at a series of dilutions. The solutions were Newtonian, and the viscosities obeyed the equation

$$\eta_{sp}/c = [\eta] + k'[\eta]^2 c$$

where $c$ is concentration of deoxyribonucleate in gm./ml. and $k' = 0{\cdot}77$ (cf. the values of 0·77 and 0·73 predicted for extended chains[19] and rigid rods[20]).

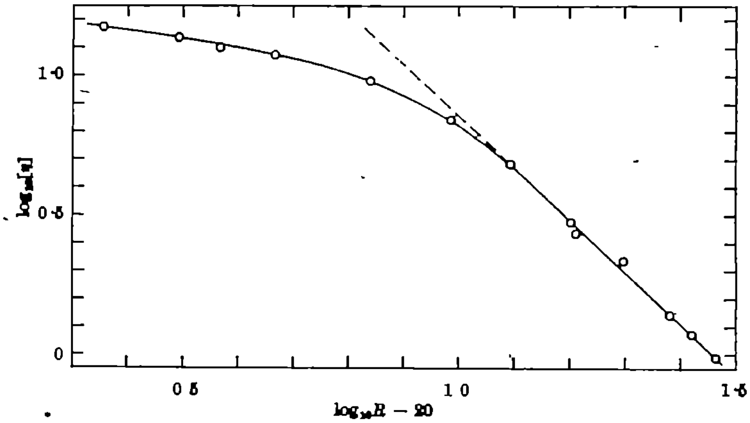

Fig. 1. Effect of γ-radiation on the intrinsic viscosity of herring sperm sodium deoxyribonucleate. Concentration of deoxyribonucleate during irradiation = 0·0043 gm./ml. Ordinate, $\log_{10}[\eta]$, where $[\eta]$ is intrinsic viscosity in dl./gm. Abscissa, $\log_{10}R$, where $R$ is radiation dosage in eV. gm.$^{-1}$. Dose-rates employed in the range 1·1 to 1·3 × $10^{16}$ eV. min.$^{-1}$ ml.$^{-1}$. Slope of straight part of graph = − 1·86

---

* Present address: Chemistry Dept., Birkbeck College, University of London.

The viscosities of the irradiated samples were independent of rate of dose for a given dosage. They depended only on the ratio (denoted by $R$ in eV. gm.$^{-1}$) of radiation dosage (in units of eV. ml.$^{-1}$ = $1 \cdot 72 \times 10^{-14}$ röntgens) to concentration of deoxyribonucleate (gm. ml.$^{-1}$) during irradiation, which again suggests an indirect effect (cf. ref. 21). The eventual linearity of a plot of log $[\eta]$ against log $(R)$ (see Fig. 1) shows that the breakage must be random[9]. The slope of this linear portion of the curve is $-1 \cdot 86$ and, on the hypothesis of random cleavage of a single chain[9], is equal to the negative of the index $\alpha$ in the equation $[\eta] = KM_v{}^{\alpha}$, where $K$ and $\alpha$ are constants for homologous polymers and $M_v$ is the viscosity-average molecular weight. This relation arises because the probability, $p_s$, of a break in a single chain is $p_s \propto (R+R_0)$ and, when the molecular weight distribution is random, $M_v \propto (R+R_0)^{-1}$, that is, $M_v \propto R^{-1}$, when $R \gg R_0$, which applies over all the linear part of Fig. 1 (for definition of $R_0$ see ref. 9).

The value of 1·86 for the index $\alpha$ in the equation relating $[\eta]$ and $M_v$ is improbably high, being greater than the values expected[22] either for rigid rods (1·7) or random coils (0·66), and indeed synthetic polymers rarely have $\alpha$ greater than 1. The basis of this interpretation is that every break in a monomer–monomer linkage leads to a change in molecular weight, and hence in $[\eta]$. In a cross-linked double helical structure such as the deoxyribonucleate, cleavage of a *single* monomer–monomer linkage (that is, an internucleotide bond) would not be expected to lead to an immediate change in molecular weight and intrinsic viscosity, $[\eta]$. Such changes would only happen if two breaks occurred in opposite positions, one in each of the two polynucleotide strands of the double helix (*B* and *B′*, Fig. 2). It is of interest that the fragments so produced (*B′* in Fig. 2) are not unlike the interrupted double helical model suggested by Schachman and Dekker[13]. The joint probability, $p_D$, of such a complementary double break is $p_D = p_s{}^2 \propto (R+R_0)^2$. Hence $M_v \propto (R+R_0)^{-2}$ and the slope of the plot of log $[\eta]$ vs. log $R$ will be $(-2\alpha)$ at $R \gg R_0$, which applies over all the linear part of Fig. 1. This gives a value for $\alpha$ of $1 \cdot 86/2 = 0 \cdot 93$, which is more feasible and is intermediate between the values for a rigid rod and for a random coil[22], in agreement with other observations on sodium deoxyribonucleate[14].

The evidence that, over the range of the viscosity studies, hydrogen bonds are still present holding the two helices together comes from titration studies, which show that, at the highest value of $R$ in Fig. 1, 57 per cent of the hydrogen bonds are still present. In Fig. 3, curves I and II represent respectively the forward and back titration curves to and from *p*H 2·5 of the original deoxyribonucleate; (I) is the irreversible titration curve of a deoxyribonucleate with its adenine and cytosine amino-groups hydrogen-bonded, and (II) is the reversible titration curve of these same groups in 'denatured' deoxyribonucleate containing no hydrogen bonds[14]. Curves *A*, *B*, and *C* are the *forward* titration curves of various irradiated samples of deoxyribonucleate and show that γ-rays gradually destroy the hydrogen bonds. The back titration curves of the original (curve II, Fig. 3) and irradiated deoxyribonucleate (not shown in Fig. 3) indicate that acidic groups titrating at *p*H 4·5–5·5 and at *p*H 6·5–7 are released (for example, 0·22 group/4 moles of deoxyribonucleate phosphorus at $R = 1 \cdot 11 \times 10^{22}$ eV./gm.). These groups must comprise secondary phosphoryl end-groups, but may also include carboxyl groups at the $C_5$ of the suga moiety produced by radical attack[15]. Curves *A*, *I* and *C* of Fig. 3 have all been corrected for thes acidic end-groups, so that direct comparison can b made between them and (I) and (II).

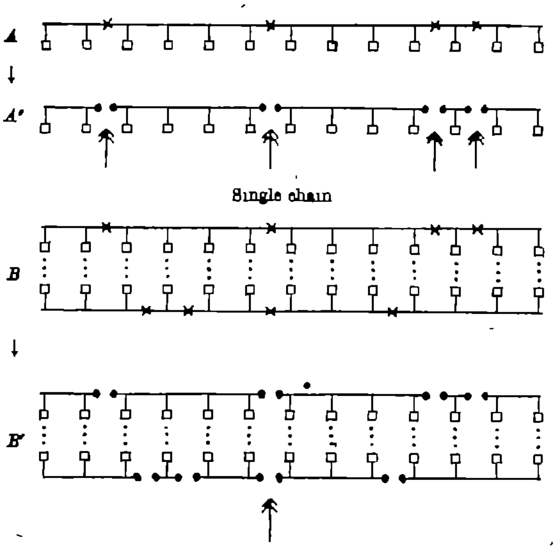

Fig. 2. Schematic diagram of the effects of random fracture of internucleotide linkages in sodium deoxyribonucleate according to two different models. (*A*) Single polynucleotide chain giving (*A′*). (*B*) Two polynucleotide chains cross-linked by hydrogen bonds, giving (*B′*).
One nucleotide, the square denoting the purine or pyrimidine base; . . . , hydrogen bond systems cross-linking purines to pyrimidines; —●, new ends formed by the internucleotide breaks; ×, positions of fracture of internucleotide linkages; ⟶, positions of breaks which alter the molecular weight and contribute to the decrease in $[\eta]$.
Both diagrams ($A \rightarrow A'$ and $B \rightarrow B'$) are drawn for a probability of rupture of an internucleotide linkage of 1/3. (Note bigger change in molecular weight for $A \rightarrow A'$)

An important feature of the titration curves (whic is also clear from the lower part of Fig. 3) is tha irradiation does not displace the forward titratio curves uniformly from (I) towards (II) and withou regard to the *p*H range, as would be expected fo random breakage of all hydrogen bonds involvin the titratable groups. In the early stages of irradiation, it is the lower part of (I) which is fir displaced towards (II). This *p*H region correspond chiefly to the titration of adenine amino-groups[1] in the intact molecule. (For clarity, Fig. 3 show neither the five titration curves between (I) and *A* which accurately confirm the unsymmetrical character of this displacement, nor other curves betwee *A* and *C*.) As the irradiation proceeds (for example curve *B*) the upper part of the curve is displace towards (II), until eventually (for example, curve *C* most of the hydrogen bonds are ruptured. It coul be concluded from this that the adenine–thymin hydrogen bonded system[15] is broken down mor rapidly than is the guanine–cytosine system and ther is indeed no *a priori* reason why these two system should have the same stability. However, it woul contrast with the random breakage of the internucleotide bonds. Alternatively, the titration curve could be explained if the internucleotide breaks o Fig. 2 facilitated the irreversible denaturation of th deoxyribonucleate double helix so that fewer group had to be ionized before complete denaturation. On the double helical model, breakage of hydroger bonds by γ-rays would not lead to a change in molecular weight until the majority of such bond

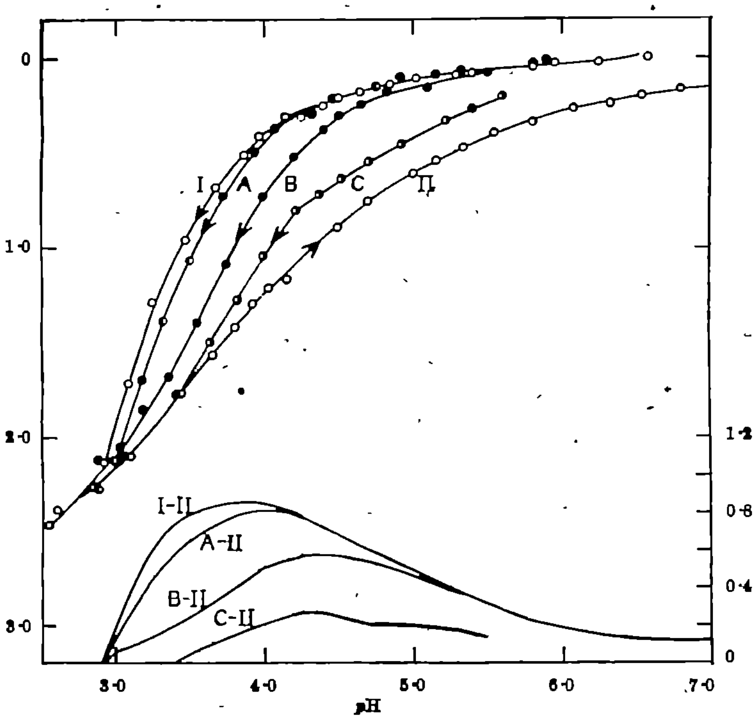

Fig. 3. Titration curves of original and $\gamma$-irradiated herring sperm sodium deoxyribonucleate. Titration conditions: 25° C., ionic strength = 0·05, concentration of deoxyribonucleate, 0·14–0·18 per cent.

*Upper Figure.* (I) and (II) forward (pH 6·0 to 2·5) and back (pH 2·5 to 7) titration curves of the original sodium deoxyribonucleate. *A*, *B* and *C*, forward titration curves (pH between 5 and 6 to pH 2·5) of deoxyribonucleate irradiated with $\gamma$-rays to different extents. Dosages, in units of (*R*): (*A*) 0·87 × $10^{20}$ eV. gm.$^{-1}$; (*B*) 2·9 × $10^{20}$ eV. gm.$^{-1}$; (*C*) 11·5 × $10^{20}$ eV. gm.$^{-1}$ Ordinate scale on the left.

*Lower Figure.* Difference curves obtained by subtracting the base bound along curve (II) from the other curves. Ordinate scale on lower right

ad been ruptured, and this justifies the interpretation f changes of [$\eta$] in terms of rupture of internucleotide onds over the range of *R* shown in Fig. 1.

As with other modes of degradation[26] which upture hydrogen bonds, there is an increase in ultra-iolet absorption of the sodium deoxyribonucleate t 258 mμ. It may be expressed as a percentage of he maximum increase in extinction, $\epsilon$, observed with high dosage ($R = 411 \times 10^{20}$ eV. gm.$^{-1}$) large nough to break all hydrogen bonds but not to lecompose the purine and pyrimidine rings, and able 1 shows that this quantity is approximately qual to the total percentage of hydrogen bonds roken (as deduced approximately from the titration urves). This is further evidence[27] that it is rupture f hydrogen bonds in the double helix which causes n increase in the ultra-violet absorption.

able 1. EFFECT OF GAMMA-RAYS ON THE ULTRA-VIOLET ABSORPTION OF DEOXYRIBONUCLEIC ACID AT 258 mμ

| | | | | |
|---|---|---|---|---|
| $0^{-20}$ *R* (eV. gm.$^{-1}$) | 23 | 29 | 35 | 111 |
| er cent increase in ultra-violet absorption, $\frac{\Delta\epsilon}{\Delta\epsilon\,\text{max.}} \times 100$ | 40 | 50 | 45 | 78 |
| r cent hydrogen bonds broken (from titration) | 33 | 42 | 43 | 80 |

It would appear that, as with some other studies f sodium deoxyribonucleate[14,24,26], the present results re best understood in terms of the existence of the ouble helical structure in aqueous solutions of deoxy-ibonucleate. The action of $\gamma$-rays consists of: ) random cleavage of internucleotide phosphate ster bonds, a decrease in molecular weight and [$\eta$] esulting when two such breaks occur at opposite positions in each polynucleotide helix; and, (*b*), rupture of cross-linking hydrogen bonds, those which link the adenine–thymine pair of bases perhaps being broken more rapidly than those linking the guanine–cytosine pair. This rupture of hydrogen bonds begins at lower dosages than those causing appreciable changes in intrinsic viscosity and the even larger dosages causing degradation of the bases[10–12].

It has been suggested[27] that there is a relationship between the pairing of the bases linked by hydrogen bonds, the complementary nature of the two helices of the deoxyribonucleic acid that this implies, and the genetic self-duplicating role of deoxyribonucleic acid in biological systems. The effects of ionising radiation on hydrogen bonding reported here show a possible chemical mechanism for the biological effects of low dosages of such radiation (and possibly also for mutational changes), since the rupture of a few hydrogen bonds would presumably impair the duplication of the deoxyribonucleic acid at that point but not elsewhere along the molecule.

We are indebted to Prof. M. Stacey for his interest and encouragement in this work and for making available the source of gamma-rays. We acknowledge also the co-operation of Dr. G. A. Gilbert in the viscosity measurements, and the receipt of a maintenance grant from the Department of Scientific and Industrial Research by one of us (R. A. C.). [Aug. 12

## New Records in Human Power

UNDER this heading Robinson, Edwards and Dill[1] published in 1937 results of investigations of five young men of international renown in distance running. Lash, who held the world's record for the 2-mile race, running on a treadmill at 21·6 km./hr. with no gradient, attained an oxygen intake of 5·35 l./min. or 81·5 ml. per kgm. of body-weight per min.[2].

In this laboratory, studies have been carried out on oxygen intake (aerobic capacity) during severe muscular work by normal, healthy children, men and women and championship athletes. Methods and results of examinations of about 260 subjects have been described by Åstrand[3,4]. In some cases an oxygen intake of 5 l./min. was obtained.

Table 1 gives the aerobic capacity and some other results for three international standard milers. Determinations of pulse-rate, pulmonary ventilation and oxygen intake were carried out during the last minutes of a 6-min. run at a speed of 20 km./hr. on a treadmill set at an angle of 1°. The highest value for oxygen intake was obtained with J. Landy, who broke the world's record in 1954 for the 1,500-m. race, that is, the same summer as that during which the present determinations were carried out. He reached an oxygen intake of 5·04 l./min. or 76·6 ml./kgm./min.

When testing the Swedish national ski-team for physical condition, submaximal work-loads were performed on a bicycle ergometer. Applying a nomogram[5], aerobic capacity was estimated from pulse-rate attained during this work. By this procedure, values of oxygen intake as high as 6·1 l./min. were estimated. As these figures far surpassed the earlier maximum, it was of great interest to obtain direct measurements of those subjects' aerobic capacity. Arrangements were therefore made to carry out some tests during the Swedish ski championships hel during 1955.

To get 'warmed up', the subjects covered a distanc of about 10 km. at a fairly high pace. Then a specia 'rucksack' carrying a Douglas bag was attached. Th skiing now continued at almost maximum speed o a horizontal track. After 3 min. the subject stoppe for a few seconds and then started to breathe vi the valve. The maximum rate of work proceede for another couple of minutes. During the las minute he was skiing uphill and the expired air wa collected in the bag. It should be emphasized tha only one experiment was carried out with each subject, for which reason the recordings are minimum values. On the other hand, the high figures for th concentration of blood lactic acid suggest an oxyge intake very close to the maximum which is attainable[3].

Table 1 summarizes the results of the experiments The highest figure recorded for oxygen intake wa 5·88 l./min. or 81·7 ml./kgm./min. The femal subject reached an intake of 3·97 l./min. or 68· ml./kgm./min.

Five of the subjects were tested performing work-load of 1,200 kpm./min. on a bicycle ergometer and the nomogram mentioned was applied. In three cases the estimated aerobic capacity diverge less than 4 per cent from that determined. For the female subject the estimated figure was 15 per cent too high. The nomogram is made up with different scales for men and women. When using the male scale for this very well-trained female skier, the estimated aerobic capacity, however, equalled that determined (4·0 l./min.).

In Table 1, values are included from an investigation of capacity for hard muscular work of eighty-six healthy, well-trained students of physical education[6]. None of those subjects, however, was of the championship class in events calling for endurance. The most striking difference between those students, on one hand, and the middle-distance runners and skiers, on the other, is found when comparing the capacity for oxygen intake. Values for vital capacity, maximum heart-rate, pulmonary ventilation and concentration of blood lactic acid were of the same order. It is probable that a high aerobic capacity

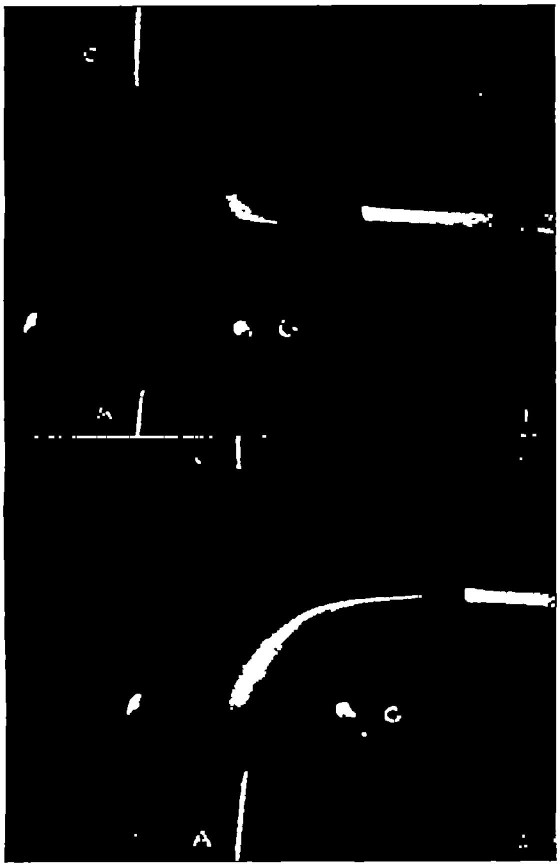
## Corona Wind Loud-speaker

Experiments made with a pair of electrodes, one arp and one blunt, show that a corona wind moves way from the sharp point independent of its polarity. the needle is positive, the wind is stronger than hen it is negative.

The wind may be controlled by placing a blunt ng or 'grid' around the sharp electrode: if this ng is maintained at the same order of voltage as ne sharp electrode, then there is a position of the tter at which comparatively small changes of the rid potential produce a maximum effect on the tensity of the corona wind and hence on the corona current. This may be explained on the assumption that lines of force which otherwise would terminate on the tip of the needle are deflected to the grid ring to an extent dependent on the relative potentials of the electrodes. Thus although the grid takes no current itself, variations of its potential can control the corona current over a wide range. An extensive experimental study of this phenomenon has been made and will be published elsewhere.



(1) Strong positive wind from needle *A*; $V_{AC}$ = 17·5 kV. and $V_{GC}$ = 8·5 kV. (2) Strong negative wind from needle *C*; $V_{AC}$ = 18·5 kV. and $V_{GC}$ = 15·2 kV.

With two sharp electrodes *A*, *C* (Fig. 1) opposed to each other, the strong positive wind greatly exceeds the negative. The interaction of the two winds causes an injected smoke stream from the region of the positive needle to avoid the negative one in an umbrella-shaped form (not shown) near the negative needle. If now the ring electrode *G* is placed around the positive needle *A*, the positive wind may be completely cut off (Fig. 2), in which case the negative wind predominates. With a positive wind adjusted to equality with the negative there is no net wind.

An alternating potential applied to the grid causes the air to pulsate and hence to become a source of sound.

With a stacked array of triodes large enough to give a reasonable acoustic area, the device becomes a loud-speaker with certain distinctive features. (*a*) It has no moving parts. (*b*) It requires no electrical power at acoustic frequencies to drive it, since the 'grid' ring takes no current. The power comes from a d.c. source across the needles. (*c*) It has a good bass response, without any bass resonance even down to zero frequency: the steady wind is the zero-frequency response. (*d*) It has a good middle- and high-frequency response smooth to 15 kc./s. (*e*) In its present form it has a severe limitation in its linearity; but a push–pull form is under construction. (*f*) Its power output under an approximately linear adjustment is about 0·1 mW. per sq. cm. of matrix area, a figure comparable with types of electrostatic loud-speaker using diaphragms. The d.c. power input is about 50 mW. per sq. cm. at 12 kV. (*g*) The polar distribution of sound may be varied at will by varying the shape of the matrix. It does not need to be planar.

## Magnetic Moment of an Excited State of the Fluorine-19 Nucleus

There is a well-known technique[1] for the measurement of magnetic moments of short-lived nuclear states. A strong external magnetic field applied to a radioactive source which emits $\gamma$-rays in a cascade process will influence the nuclear spin of the intermediate state, and thus change the $\gamma-\gamma$ angular correlation. The strength of the interaction is a measure of the nuclear moment, and the theory of the process has been worked out[2,3].

The same principle has been applied to a study of the angular distribution of $\gamma$-rays resulting from the nuclear reaction:

$$p + {}^{19}\mathrm{F} \rightarrow p' + {}^{19}\mathrm{F}^{**} \rightarrow p' + \gamma + {}^{19}\mathrm{F} \qquad (1)$$

where the intermediate nucleus (${}^{19}\mathrm{F}^{**}$) is known[4] to have a lifetime of $(1{\cdot}0 \pm 0{\cdot}2) \times 10^{-7}$ sec., spin 5/2 and excitation 197 keV. A uniform vertical magnetic field was applied normal to the beam of the Canberra H.T. set, and protons of 873 keV. were allowed to strike a target of sodium fluoride (0·3 mgm./cm.$^2$) evaporated on copper. Gamma-rays were detected at different angles in a horizontal plane with a photomultiplier (employing a 1-in. diameter × $\frac{1}{2}$-in. sodium iodide (thallium) crystal) mounted on a rotatable table, and the pulse spectrum was recorded on a kicksorter.

Fig. 1 shows the experimental results and a theoretical plot of the function

$$\frac{W(0°) - W(100°)}{W(0°) + W(100°)} = a\,\frac{0{\cdot}97 - 0{\cdot}17x}{1 + x^2} \qquad (2)$$

which approximates (to within ± 2 per cent) to a formula given by Alder[2]. This formula (calculated for $\gamma - \gamma$ correlations) can be shown to apply to the present case since (i) one averages over ($p' + {}^{19}F^{**}$) directions and (ii) the angular distribution function[3] is, in the absence of external fields, of form:

$$W(\theta) = 1 + A\cos^2\theta$$

where $A = \dfrac{2a}{1 - a}$. In equation (2), $x = 2g\mu H\tau/\hbar$, where these quantities have meanings given by Alder. The solid and dotted curves correspond to $g = +\,1{\cdot}35$ and $g = -\,1{\cdot}90$ respectively.

If one assumes, on the basis of the nuclear shell model, that the 197-keV. level approximates to an odd $d_{5/2}$ proton orbit, the Schmidt value[6] for the $g$-factor is $+\,1{\cdot}9171$. Thus, we accept the positive result and, taking account of errors in this experiment and the life-time measurement,

$$g \text{ (197 keV. level)} = +\,(1{\cdot}35 \pm 0{\cdot}35).$$

A decoupling experiment[7] in which a magnetic field of 8,000 oersteds was applied along the beam axis failed to increase the anisotropy factor $A$ above the zero-field value 0·42 ± 0·02, so one may assume that the fluorine-19 nucleus was not magnetically coupled in the sodium fluoride target. Using a manganese fluoride target, however, a value $A = 0{\cdot}10 \pm 0{\cdot}02$ was obtained; but a decoupling experiment again failed to restore any anisotropy. In this case the extranuclear influence at work may be electronic paramagnetic relaxation, though the shortness of relaxation time in manganese fluoride makes this improbable[8]. If, as seems likely, the tetragonal symmetry of manganese fluoride results in anisotropic hyperfine structure, a decoupling field can have little influence. In support of this, the reduction of $A$ from 0·42 to 0·10 is just what would be expected[3] were strong anisotropic hyperfine structure present in random arrangement of microcrystals. A thin possible explanation is that quadrupole interactio are present: this could only be investigated usin single crystals.

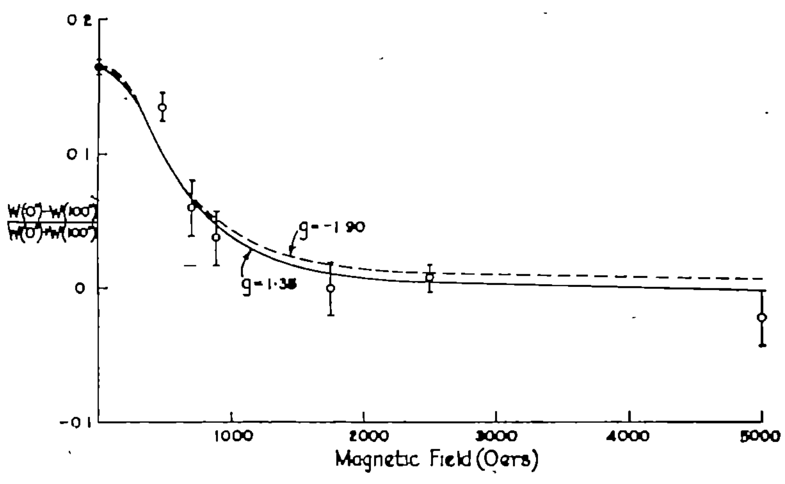

Fig. 1. Anisotropy as a function of the magnetic field-strength

Further experiments are proceeding, and th work will be reported more fully elsewhere.

# Thermal Expansion of Coal

THE following observations, which form part of a investigation into the pore structure and surface are of coal, are reported here in view of the curren interest[1,2] in the expansion moduli of coal.

Table 1

| Coal | Carbon (per cent, dry, ash-free) | Volatile matter (per cent, air-dry) | Mean linear coefficient ($\bar{a} \times 10^6$) |
|---|---|---|---|
| New Cross Hands | 93·8 | 5·5 | 24 2 |
| Cefn Coed | 93 0 | 6·5 | 25·4 |
| Cwmgwrach | 91·8 | 9·5 | 28·7 |
| Deep Navigation | 91 3 | 14·7 | 31·0 |
| Pochin | 91·1 | 19·5 | 33·2 |
| Wyllie | 89·1 | 25·0 | 35·4 |
| Beynon | 87·4 | 30·2 | 37·0 |
| Cwm Carn | 84·5 | 35·5 | 39 1 |
| Ellington | 79·4 | 38 0 | 37·1 |

The bulk modulus of expansion of a series of coals has been determined by a dilatometric method in which about 40 gm. of bright coal (10–18 mesh B.S. test sieve) was confined under a mercury–thallium amalgam in a steel bomb, and the expansion observed by the change in height of the amalgam in a 70-cm. length of precision-bore tubing of 1·5 mm. internal diameter. Calibration was effected by measurements with the dilatometer empty of coal, and the accuracy of the method confirmed by measurements with 10–18 mesh (B.S. test sieve) borosilicate glass of known modulus.

The temperature-range was 0° to − 47° C., covered by using a series of eight refrigerant baths, in which the steel bomb was immersed up to the junction with the precision-bore glass tubing. With the exception of the Ellington coal, all the coals examined were from the South Wales Nine Foot Seam, which is believed to represent coals of the same origin in widely different states of coalification.

Results for all the samples used are shown in Table 1, the expansions being given as mean linear coefficients to facilitate comparison with the results of other workers.

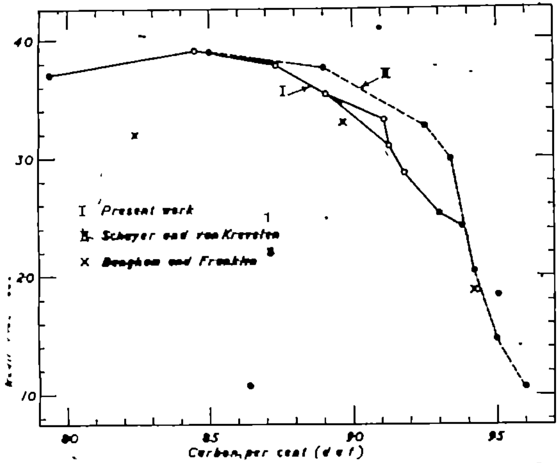

Fig. 1. Relationship between thermal expansion and rank of coal

It should be noted that the expansion coefficient appears to be even better related to the volatile matter than to the carbon content.

The results are shown graphically in Fig. 1. The broken line has been calculated from the results of Schuyer and van Krevelen[1] for expansions perpendicular and parallel to the bedding plane, assuming the expansion to be isotropic in the latter plane. The agreement between the two main sets of independent observations is better than usually expected for measurements on coals of different origin. The values found by Macrae and Ryder[2] refer only to the expansion parallel to the bedding plane and are too large to be included on this graph; but it is interesting to note that the different results obtained by them for two samples of the same coal, measured parallel to the bedding plane, could mean that anthracite is anisotropic in all three major planes. This is not well supported, however, by the agreement, already mentioned, between the mean coefficients obtained by direct observation of the cubical moduli and those calculated from the separately measured parallel and perpendicular moduli.

A full description of the apparatus, and a discussion of the results will appear elsewhere.

This work forms part of the programme of research of the Fuel Research Board of the Department of Scientific and Industrial Research, and is published by permission of the Director of Fuel Research.

## Separation of Ions at Crystallization of Water

According to Workman and Drost-Hansen[1], a substantial amount of fluorine ions is incorporated into ice if it is crystallized from diluted solutions of cæsium fluoride. We have studied this process further, and found that it is not fluorine ions which are incorporated into ice but rather electrically neutral molecules of hydrogen fluoride.

One half of a diluted solution of cæsium fluoride in water was frozen and the ice separated from the remaining liquid. The water used had been distilled in a vacuum and was free of impurities, especially carbon dioxide. The *p*H of the remaining liquid was found to be higher than that of the thawed ice. An example is given in Table 1.

Table 1

| Sample | mol. F′/l. | *p*H | F′ (mgm./10 cm.³) |
|---|---|---|---|
| Original solution | $5 \cdot 82 \times 10^{-3}$ | 8·0 | 1·105 |
| Non-frozen liquid | $8 \cdot 43 \times 10^{-3}$ | 8·5 | 1·658 |
| Ice | $9 \cdot 7 \times 10^{-4}$ | 7·0 | 0·184 |

The accuracy of these measurements was not very high because the determination of the *p*H-value was carried out by means of an indicator. We are now carrying out more precise measurements.

The above experiments agree with results on the incorporation of hydrogen fluoride into ice. We found that small quantities of hydrogen fluoride can be built into the ice lattice. According to previous investigations[2], ammonium fluoride forms mixed crystals with ice in a range up to about 10 per cent ammonium fluoride. The replacement of water molecules in ice by ammonium fluoride seems to be facilitated by the fact that the ratio H/(N+F) is the same as the ratio H/O in water. Since, if water molecules are replaced by hydrogen fluoride, this ratio is smaller than 2 : 1, a greater disturbance by missing hydrogen bonds is introduced if water is replaced by hydrogen fluoride. This exemplifies the great influence of hydrogen bonds on the stability of the ice lattice.

This investigation was carried out under a contract of the Snow, Ice and Permafrost Research Establishment, Corps of Engineers, U.S. Army.

## Magnetic Catalysis of the Decarboxylation of Oxaloacetic Acid

Kinetic studies of the decarboxylation of phenylmalonic acid in aqueous solution in the presence of high concentrations of rare-earth ions show that diamagnetic ions have little effect on the rate of reaction, while the paramagnetic dysprosium ion leads to an acceleration in rate of the order of 10 per cent[1,2]. Rare-earth ions do not appear to become co-ordinated appreciably with phenylmalonic acid. Since any magnetic effect must be a very sensitive function of the distance between catalyst and substrate, a study is now being made of the kinetics of decarboxylation of an acid, the anions of which are known to become co-ordinated more strongly with metal ions.

The kinetics of decarboxylation of oxaloacetic acid and its anions have been investigated by Pedersen[3]. We have now measured the rates of decarboxylation of this acid in aqueous solution at 37° in the presence of lanthanum, gadolinium, yttrium, dysprosium and lutecium ions (Clayton, J. P., and Gelles, E., unpublished results). The manometric method[4] employed for following the evolution of carbon dioxide yields first-order rate coefficients accurate to ± 3 per cent. *p*H measurements show that the thermodynamic dissociation constants $(M^{3+})\,(A^{-})/(MA^{+})$, where $M^{3+}$ represents a rare-earth ion and $A^{=}$ the divalent oxaloacetate anion, are around $2 \times 10^{-4}$ at 25° (Gelles, E., and Nancollas, G. H., unpublished results). At the concentrations used in the kinetic experiments, a small fraction of the oxaloacetic acid is in the form of rare-earth complex; but with constant initial conditions of concentration and $p$H, the concentrations of uncomplexed species are effectively constant for different rare earths.

The effect of the rare-earth ions on the rate of decarboxylation might be expected to be a smooth function of the chemical activity of the ions. A linear free-energy relationship between rate and equilibrium data is indeed found for the diamagnetic ions. Fig. 1 shows a plot of the logarithms of the first-order rate coefficients ($\log_{10}$, min.$^{-1}$) in a typical set of experiments against the logarithms of the thermodynamic stability constants of the rare-earth ethylenediaminetetra-acetates[5]. In the set of kinetic experiments, the initial $p$H was constant at 1·02, and the initial concentrations in moles/litre of oxaloacetic acid and rare-earth ion were 0·0300 and 0·100 respectively. The reaction-rate is due almost entirely to the complexed species, the rate coefficients used in Fig. 1 being corrected for the small amount of uncatalysed reaction. Size of circle indicates the probable limits of experimental errors. It is seen that for the diamagnetic ions $La^{3+}$, $Y^{3+}$ and $Lu^{3+}$, an excellent linear free-energy relation is found.

For the paramagnetic ions $Gd^{3+}$ and $Dy^{3+}$, an acceleration in rate of decarboxylation is observed greater than that predicted by interpolation from the linear free-energy relationship. For $Gd^{3+}$ it is about 20 per cent, and for $Dy^{3+}$ about 10 per cent. This additional catalysis by the paramagnetic ions increases with increasing ion concentration, and it can be attributed specifically to the presence of unpaired $4f$ electrons in these ions.

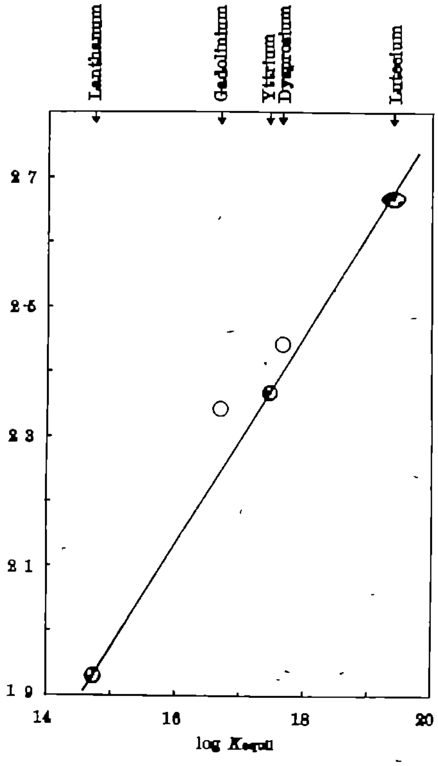

Fig. 1

It is possible that unpaired electron spin–sp interactions between catalyst and substrate result some contribution from a favourable non-adiabat reaction process.

With further kinetic data at lower concentratio (Gelles, E., unpublished results) and the appropria equilibrium constants (Gelles, E., and Nancolla G. H., unpublished results), it will be possible obtain rate-constants for the individual compl species and to make a direct comparison betwe rate and equilibrium properties for one and the sa substrate.

## Cosmic Sources of Deep-Sea Deposits

Black magnetic spherules found in deposi collected by the *Challenger* Expedition (1872–7 have been recognized as being probably of cosmi origin[1]. These spherules represent but a very sma fraction of the sediments by mass, and have littl effect on their average chemical composition. Th relatively high nickel content of deep-sea deposit in the Pacific Ocean led Pettersson and Rotschi[2] t suggest a cosmic origin for the excess nickel. Th amount of accretion of cosmic matter by the eart required to account for this excess would not con flict with some estimates of the density of matter i the zodiacal-light cloud[3], although other estimate would fall short of the requirements.

The frequency of spherule diameters[4], extracte from samples of deposits obtained by the Swedis Deep-Sea Expedition, showed excellent agreemen with the theoretical frequency for micro-meteors[3] for the following distribution of velocities:

| Velocity (km./sec.) | 11·5 | 13·2 | 16·9 | All |
|---|---|---|---|---|
| Percentage | 33·3 | 16·7 | 50·0 | 100·0 |

The velocity-range is close to what would be ex pected for primordial dust, spiralling into the su under the Poynting–Robertson effect[5], in direc motion and in orbits of small eccentricity. The mai component of the velocity is due to the earth's attraction, which sets 10·8 km./sec. as a lower limit to it. The agreement of the frequency of diameters with theory lends support to the hypothesis that the spherules are of cosmic origin.

However, the cosmic origin of the general nickel excess has been subjected to doubt by Laevastu and Mellis[4], on the basis of the ratio of iron to nickel, and by Smales and Wiseman[6], from the relative abundance of nickel, cobalt and copper. The relative abundances of these elements agree with those of terrestrial sources, and greatly disagree with those of meteorites. Laevastu and Mellis suggest that iron and nickel in the oceanic red clay may be due in part to co-precipitation from sea water.

Nevertheless, the conclusion that the excess nickel is not of cosmic origin would be premature. Meteorites are believed to be fragments of larger bodies—planets—destroyed in collisions; in such a case they are the product of astrochemical differentiation in the interior of the planet, which preceded the ble 1. AVERAGE ABUNDANCE RATIOS OF IRON, NICKEL, COBALT AND COPPER

| | Fe/Ni | Ni/Co | Ni/Cu |
|---|---|---|---|
| Deep-sea red clay (ref. 6) | — | 3·1 | 0·85 |
| Globigerina ooze (ref. 6) | — | 4·1 | 0·77 |
| Pacific deep-sea core (ref. 4) | 100 | — | — |
| Oceanic rocks (ref. 6) | — | 4·3 | 1·2 |
| Solar atmosphere (Russell ; Unsöld) | 16 ; 50 | 2·5 ; 8 | 10 ; 50 |
| Earth's crust (Clarke and Washington) | 250 | 10 | 0·3 |
| Meteorites (Goldschmidt ; Noddack) | 19 ; 14 | 13 ; 16 | 90 ; 100 |

tastrophe and led to the peculiar distribution of e abundances, according to the conditions in the terior and the physico-chemical properties of the lements. On the other hand, the fine primordial ust is most properly described as the product of ondensation from a gaseous medium ; there is no ood reason for assuming that in this case the lection of the elements would be identical with that meteorites ; on the contrary, the composition of e surface layers of the earth and the solar tmosphere could be expected to be more akin than eteorites to that of the primordial dust.

The distinction between meteorites and meteoric ust is not only a theoretical one. An analysis of eteor observations, obtained during the Arizona xpedition[7], indicates that the great majority of aked-eye meteors are fluffy or spongy 'dustballs' hich decompose, not by vaporization or spraying om a solid dense nucleus, but simply by crumbling nder an aerodynamic pressure as low as $10^4$ dyne/ m.[8]. Recent results from Harvard Super-Schmidt hotographs confirm this[9]. The small meteors are robably similar to snowflakes—the results of submation from a gaseous state. Whipple's theory of ometary structure visualizes such substance, interingled with 'ices' ; near the sun the more volatile es have evaporated, and 'dustball' skeletons remain, bserved as naked-eye and fainter meteors when hey enter our atmosphere.

These facts indicate the need for caution in applying he meteoritic analogy to the chemical composition f amorphous cosmic matter, such as would collect n the bottom of the sea.

In Table 1 the meteoritic abundances are comared with terrestrial and other cosmic abundances. he data would vary according to source ; neverheless, the sets chosen are quite characteristic. he increased abundance ratio nickel to iron in the acific core, as compared with the earth's crust, is oticeable. Although the terrestrial abundances gree best with those of the deep-sea deposits, this ould not necessarily mean a terrestrial origin of e latter ; it may be that the earth's outer crust self, being the last addition to our planet from osmic sources, is built of a material the remnants which are still falling on the earth from the odiacal-light cloud.

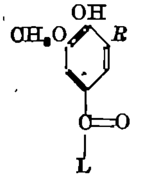
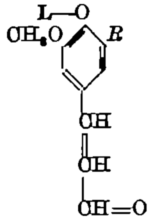
## Contribution of Residues containing Carbonyl to the Ultra-Violet Absorption of Lignins

ABSORPTION spectra and colour reactions indicate the presence in lignins of *p*-hydroxyphenylketone groups (I ; L represents the rest of the lignin molecule)[1] and 4-O-substituted cinnamaldehyde groups (II)[2].

(I)



(II)



*R* = H, or $OCH_3$

Both types of carbonyl-containing residues have an absorption band near 350 mμ, but it has been found possible to distinguish such groups by their different rates of reduction with sodium borohydride in dilute (0·01 *N*) sodium hydroxide.

Table 1. REDUCTIONS WITH SODIUM BOROHYDRIDE

Solutions of the following molarity in 0·01 *N* sodium hydroxide were used. *iso*-Vanillin, 2 × $10^{-4}$ *M* ; acetovanillone, veratric aldehyde, 5 × $10^{-4}$ *M* ; *p*-hydroxybenzaldehyde, vanillin, syringaldehyde, ferulic aldehyde, 3 : 4-dimethoxycinnamaldehyde, 2 × $10^{-5}$ *M*. Each solution (2 c.c.) was mixed with 0·2 *M* sodium borohydride in 0·01 *N* sodium hydroxide (1 c.c.), and the reaction followed spectrophotometrically at suitable wave-lengths in a 1-cm. cell. Temperature 20°

| Substance | Half-reaction time (min.) |
|---|---|
| 3 : 4-Dimethoxycinnamaldehyde | 1 |
| Veratric aldehyde | 2 |
| *iso*-Vanillin | 20 |
| Ferulic aldehyde | 56 |
| Vanillin | 116 |
| *p*-Hydroxybenzaldehyde | 139 |
| Syringaldehyde | 156 |
| Acetovanillone | 1,180 |

Carbonyl compounds which are phenolic and ionized in 0·01 *N* sodium hydroxide are reduced more slowly ; though in *iso*-vanillin, with the carbonyl in the meta position, this effect is least marked.

With four 'native' lignins, the effect of reduction with sodium borohydride is in each case a diminution in extinction in the 350-mμ region. Two stages can be discerned in this : a rapid stage concluded in about thirty minutes, and a slower stage lasting many hours (Fig. 1). Comparison of rates of reduction with those described in Table 1 makes it seem likely that the groups reduced in the rapid stage belong to the non-ionized category. 3 : 4-Dimethoxycinnamaldehyde has an absorption band in the correct position (335 mμ ; giving on reduction 3 : 4-dimethoxycinnamyl alcohol with absorption bands at 260 mμ and 290 mμ), and this is consistent with the presence of rapidly reduced groups of type II in these four lignins.

The analogy between these groups and 3 : 4-dimethoxycinnamaldehyde was strengthened in the case of aspen by a consideration of the effect of *N* sodium hydroxide. In this reagent, 3 : 4-dimethoxycinnamaldehyde is decomposed with a half-reaction time of 55 min. at 20° to veratric aldehyde, which has absorption maxima at 277 mμ and 306 mμ, so that the absorption in the 340–350 mμ region diminishes to zero. The extinction of aspen 'native' lignin in the region of 340–350 mμ diminishes by 40 per cent under the same conditions with a half-reaction time of 60 min. These similarities of behaviour in *N* sodium hydroxide suggest that a like process may be occurring in both cases, and that groups of type II in aspen 'native' lignin may undergo a reversed-aldol reaction in *N* sodium hydroxide with the elimination of acetaldehyde.

Table 2

| | $E$(1%, 1 cm.) at 350 mμ due to: | | | |
|---|---|---|---|---|
| | Extinction of groups rapidly reduced by sod. borohydride (Groups of type II) | Residual extinction (Groups of type I) | Extinction in weakly acid solution (Groups of type II) | Difference in extinction between alkaline and weakly acid solution (Groups of type I) |
| Aspen 'native' lignin | 33·3 | 16·8 | 31·9 | 18·3 |
| Horse chestnut 'native' lignin | 9·7 | 71·2 | 18·3 | 62·2 |

The second stage in the reduction of the four 'native' lignins by sodium borohydride in 0·01 $N$ sodium hydroxide consists of a very slow further diminution in absorption at 350 mμ. In the case of aspen and horse chestnut lignins, the absorption in this region is eventually removed almost completely, and the wave-lengths of absorption and rates of reduction of the slowly reduced groups are both consistent with their having structures of type I. If this is so, then the two lignins in question show great contrast in the relative amounts, measured in terms of extinction at 350 mμ, of groups of types I and II. A check on this is provided by an examination of the absorption spectra of these lignins in acid and in alkaline solutions. Groups of type I absorb at 350 mμ only when ionized, whereas groups of type II absorb at 350 mμ at all $p$H's. The figures obtained by this method are compared with the figures obtained by reduction with sodium borohydride in Table 2.

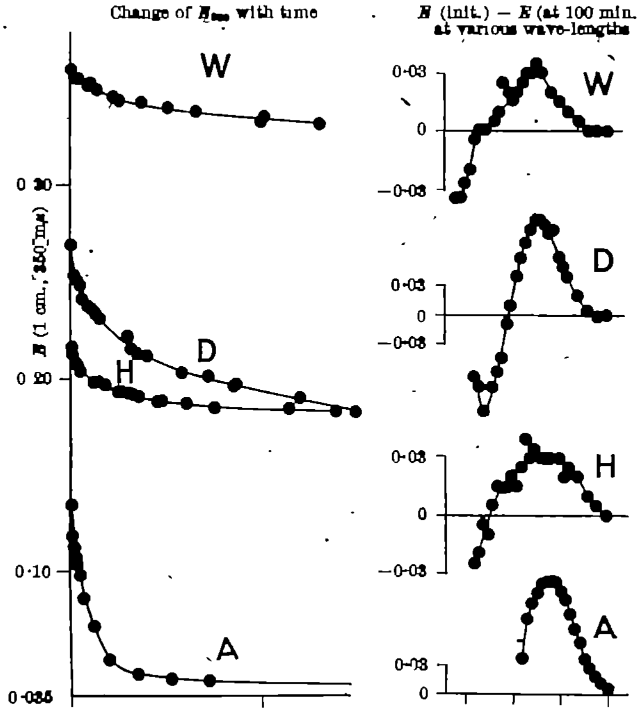


Fig. 1. The rapid stage in the reduction of 'native' lignins with sodium borohydride in 0·01 $N$ sodium hydroxide. Concentration of each lignin, 2·07 × $10^{-3}$ gm./100 c.c.; concentration of sodium borohydride, 2·50 × $10^{-3}$ gm./100 c.c.; temperature, 20°. $W$, wheat straw native lignin; $D$, douglas fir native lignin; $H$, horse chestnut native lignin; $A$, aspen native lignin

It can be seen that there is a reasonable agreeme between the relative amounts of groups I and calculated by each method.

While the conclusions reached must be regarded tentative, depending as they do entirely on specte photometric measurements, yet it seems that duction with sodium borohydride, followed specte photometrically, offers a convenient method measuring cinnamaldehyde groups in 'native' ligni The diminution in absorption at 350 mμ is only index of these groups, since the exact extinction a wave-length of maximum absorption will va depending on whether $R$ = H, or OMe.

## Chlorophyll Spectra and Molecular Structure

During experiments on pigment orientation chloroplasts and grana, it was necessary to determi the directions in which linearly polarized light preferably absorbed in a pigment molecule. Th preference corresponds to the directions of maximu transition probability of the electronic transitio which give rise to the different absorption bands i the spectra. By studying dichroism a polarization of fluorescence for chlorophyll $a$, bacteriochlorophyll and the correspondi phæophytins, these directions have been i vestigated.

*Dichroism.* Pigments were oriented in lecith or ammonium oleate by pressing between microscope slide and a cover glass. Absorptic was measured with a barrier-layer photocell photographically. For planar molecules approximate symmetrical shape, such as th porphin derivatives, it is in this way possible t distinguish between absorption in, or perpe dicular to, the plane of the molecule. For th chlorophylls mentioned, it was concluded tha absorption occurs in the plane of the porphi heads in the spectral region from 750 to 400 m

*Polarization of fluorescence.* In Fig. 1 th polarization and absorption spectra of bacteri chlorophyll and bacteriophæophytin and in Fi 2 those of chlorophyll $a$ and phæophytin $a$ a presented. The observations show that th direction of the transition responsible for th band at 590 mμ in bacteriochlorophyll is sit ated perpendicular to the transition directio at 780 mμ. In bacteriophæophytin the band 590 mμ is shifted to 535 mμ.

The chlorophyll $a$ spectrum shows a ban due to a second transition at 580 mμ. A this wave-length the absorption due to th second transition overlaps the tail of the band due to transition I. This is shown in th fluorescence spectrum, which is to a goo approximation a mirror image of the absorptio bands of I. Taking this overlap into account, can be calculated that in chlorophyll $a$ als

Table 1

| ransition | Measured | | | Calculated | | |
|---|---|---|---|---|---|---|
| | Orient. | λ(mμ) | $\epsilon_{rel.}$ | Orient. | λ(mμ) | $\epsilon_{rel}$ |
| I | $\perp$ | 765 | 70 | $\perp$ | 1,150 | 100 |
| II | $\parallel$ | 530 | 30 | $\parallel$ | 620 | 100 |
| III | $\perp$ | (460) | <5 | $\perp$ | 450 | 100 |
| IV | $\parallel$ | 385 | 60 | $\parallel$ | 435 | 100 |
| V | $\perp$ | 365 | 100 | $\perp$ | 330 | 100 |

ansition II is perpendicular to I. In phæophytin *a*, ansition II is shifted to 525 mμ.

The values of *p* in the Soret band of chlorophyll *a* dicate that, contrary to the views of Perrin[1] and upp and Kuhn[2], here also there is overlapping two transitions: one with a maximum at 435 mμ rpendicular to I, and one with a maximum at 15 mμ parallel to I. In bacteriochlorophyll also, the oret band is most probably caused by two transions, one at 390 mμ perpendicular to I and one at 0 mμ parallel to I.

The maximum at 510 mμ in the polarization ectra of bacteriochlorophyll and bacteriophæophytin ay be ascribed to a separate transition with a small ansition probability. In phæophytin *a* and *b* the aximum in this spectral region corresponds to an bsorption band of measurable intensity.

Longuet-Higgins[3] and Platt[4] have calculated spectral ata for the conjugated ring structures of tetrahydroporphin ('long-field' spectrum) and porphin round-field' spectrum) on the basis of the molecular rbital theory. In Table 1 the values of orientation, ave-length (λ) and maximum extinction coefficient ε) measured and calculated are compared for acteriophæophytin and tetrahydroporphin.

The measurements do not give an absolute orientaion of transition I in the porphin plane. For various reasons the authors mentioned assumed transition I to vibrate perpendicular to the elongation of the conjugated system. This suggestion was supported by the fact that transition II, vibrating parallel to this elongation, is shifted but slightly when changing from bacteriophæophytin into phæophytin *a*. Chlorophyll *b* showed a somewhat less pronounced polarization spectrum, being closer to a 'round-field' spectrum than chlorophyll *a*.

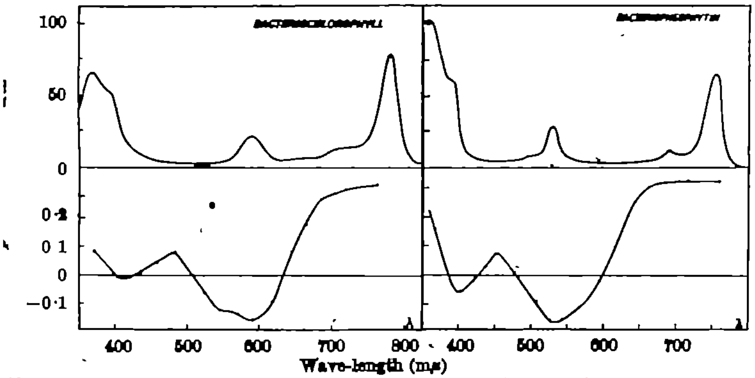

Fig. 1. Absorption spectrum and fluorescence polarization spectrum of bacteriochlorophyll and bacteriophæophytin in cyclohexanol ($\eta$ = 0·66). $\epsilon_{rel.}$ denotes relative extinction coefficient; *p* is degree of polarization

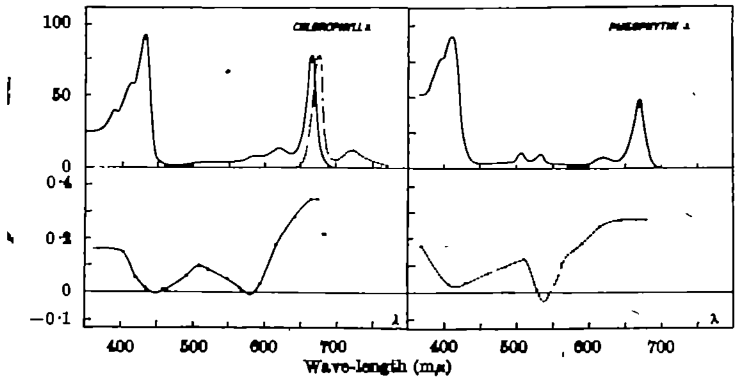

Fig. 2. Absorption and polarization spectrum of chlorophyll *a* and phæophytin *a*

A full account of these and related measurements will be published elsewhere.

## Use of Acid-Base Indicator for Quantitative Paper Chromatography of Sugars

QUANTITATIVE methods of paper chromatography tend to be unsatisfactory largely because of the very small amounts of substance separated. In the case of sugars, the spots are generally located by guide strips, which are an additional source of inaccuracy. Giri[1] has recently shown that relatively large amounts of sugars can be separated by circular chromatography. The same author and Parihar[2] attempted to recover the sugars by running the solvent off the paper and collecting it in fractions; however, they did not achieve quantitative separation.

In the method described here, the sugars are separated by circular chromatography and are then shown up by an acid-base indicator. The latter does not destroy the sugars, which can then be cut out, eluted from the paper and estimated.

The solution under test is applied to the centre of a Whatman No. 3 paper (17 cm. diameter); 0·2 ml. containing up to 50 mgm. total sugars was found to be suitable. The paper is dried and a wick put through the centre. It is then developed in the normal way, using a desiccator as the cabinet. The desiccator has a clock glass in place of the usual wire gauze, and resting on this is a Petri dish serving as solvent reservoir. More solvent is placed in the bottom of the desiccator to saturate the atmosphere.

After developing, the paper is dried well and sprayed with an indicator solution of the following composition: 40 mgm. bromocresol purple and 100 mgm. boric acid dissolved in 100 ml. methanol to which 7·5 ml. of 1 per cent borax solution is then added. Sugars are shown up yellow against a blue background. The colour difference fades in a few minutes and the position of the sugars is therefore marked immediately with a pencil. This is best done under ultraviolet light.

Table 1. DEXTROSE SOLUTION, 16 HR. IN *n*-PROPANOL (6) : ETHYL ACETATE (1) : WATER (3)

| Amount applied (mgm.) | Amount recovered | Difference |
|---|---|---|
| 9 95 | 10 04 | 0 09 |
| 9 88 | 9 95 | 0·07 |

Table 2. MIXTURE OF LACTOSE AND SUCROSE, 16 HR. IN *n*-PROPANOL (6) : ETHYL ACETATE (1) · WATER (3)

| Solution applied (ml.) | Sugar | Amount applied (mgm.) | Amount recovered (mgm.) | Difference (mgm.) |
|---|---|---|---|---|
| 0 1955 | Sucrose | 19 55 | 19 72 | 0·17 |
| | Lactose | 4·89 | 4 98 | 0 09 |
| 0·1962 | Sucrose | 19 62 | 19 90 | 0·28 |
| | Lactose | 4 91 | 4 98 | 0 07 |

This spray was first proposed by Bradfield and Flood[3] for the detection of polyhydric alcohols (with which it was said to give a strong reaction) in the presence of sugars. Under the conditions described here, it was found to show up sugars satisfactorily. A complex is probably formed between the sugar and the boric acid, giving rise to a stronger acid than boric alone.

The rings containing the sugars are cut out. A short length of filter paper is attached to each ring and this is fastened to dip into a trough filled with water in a normal chromatography cabinet. The sugars are eluted by capillary flow into flasks placed at the bottom of the cabinet. They are then estimated by the complexometric method of Potterat and Eschmann[4,5]. This is particularly suitable for the amounts separated as it gives good results over the range 2–40 mgm. of sugar.

In order to check whether the indicator had any effect on the sugar, pure dextrose solution was chromatographed. The results are given in Table 1.

The completeness of resolution can be seen from results on a solution containing 10 per cent sucrose and 2·5 per cent lactose. This was chosen to simulate the sugars in milk chocolate (Table 2).

Most sugars found in foods can be separated by one overnight run in *n*-propanol (6) : ethyl acetate (1) : water (3). In order to separate dextrose and fructose, four successive runs in formic acid (1) : *n*-butanol (5) : water (4) were found necessary. The first run is carried out overnight. The paper is then dried, run again and, for this and the next runs, is dried as soon as the solvent reaches the edge. Maltose and lactose could not be separated.

Thanks are due to Mr. G. H. Beere for his help and to Dr. A. A. Houghton, who directed this work.

# Incorporation of Phosphorus-32 into the Malpighian Tubes during the Metamorphosis of *Culex pipiens*

THE Malpighian tubes are organs with a secretory and a regulatory function with regard to water and salt balance. Studies were made to determine whether, and how, they influence the phosphate-level of larvæ and pupæ of *Culex pipiens* during metamorphosis.

The application of phosphorus-32 was acco plished very simply by placing larvæ in tap wat containing different concentrations of radioacti phosphorus. Pupæ did not take up phosphorus fro the environment. In order to determine whether th incorporation of phosphorus-32 into the Malpighi tubes varies during metamorphosis, the followi experiment was carried out. Early and late 4th inst larvæ were put into a solution of phosphorus-32 f 24 hr. and then removed to tap water. Twenty-fo hours after the administration of the phosphorus, th Malpighian tubes were isolated from the larvæ an from pupæ which had reached the pupal stage duri the time of application of phosphorus-32. Th radioactivity was measured by means of a Geige Müller counter. The age of the animals used w determined by the size of the leg and wing *Anlage*

The changes in the incorporation of phosphorus-3 into the Malpighian tubes of larvæ and pupæ a shown in Fig. 1. A great accumulation of pho phorus-32 occurs in the cells of the Malpighian tub of 4th instar larvæ near pupation and in the pupa The amount then remains more or less constant du ing the rest of metamorphosis. The greatest part c the phosphorus-32 is incorporated in acid-solub substances (10 per cent trichloracetic acid or 2 pe cent perchloric acid) (Fig. 1). The small amount o residual phosphorus-32 occurs as ribonucleic acid lipoids and phosphoproteins, as can be conclude from digestion with ribonuclease and from extractio experiments.

The phosphorus is localized in granules about 1–3 in diameter. These granules are absent from th Malpighian tubes of young 4th instar larvæ They make their appearance for the first time i larvæ nearing pupation, and then persist into th imagos (Fig. 2). They show a strong affinity for basi dyes and are soluble in 5 per cent trichloracetic aci or 2 per cent perchloric acid. Toluidine-blue is boun in the metachromatic form which is, furthermore, no resistant to an alcohol treatment. The real natur of the phosphates is not yet clear. Possibly they ar polyphosphates, which occur in many lower organisms and which could also be demonstrated in som insects[1]. These phosphate-containing granules ar

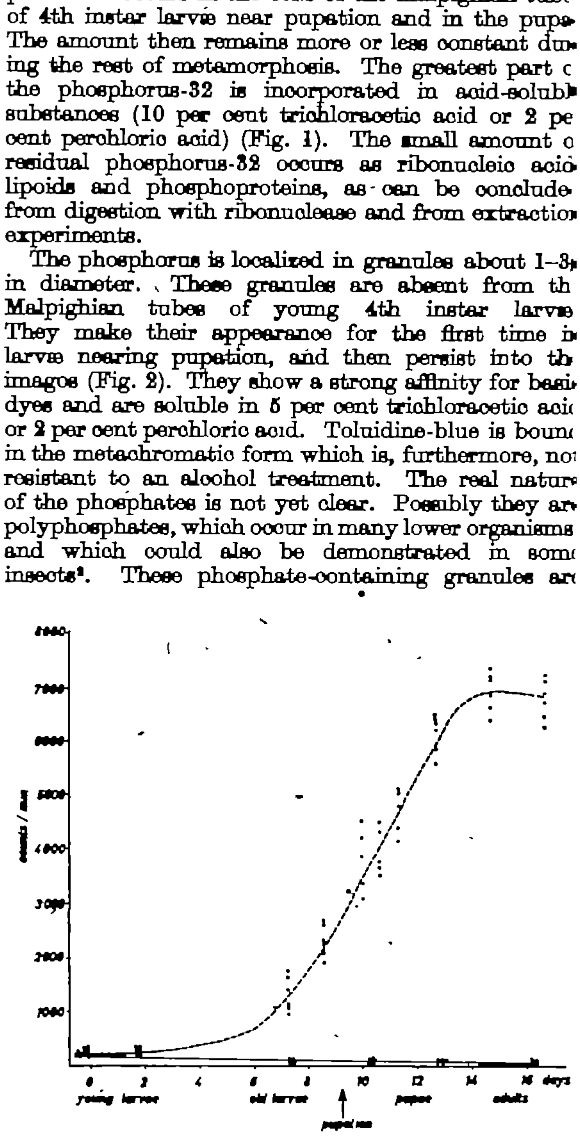

Fig. 1. The incorporation of phosphorus-32 into the Malpighian tubes of *Culex pipiens* during metamorphosis. – – – –, phosphorus-32 accumulated in the cells; ———, after extraction with 10 per cent cold trichloracetic acid

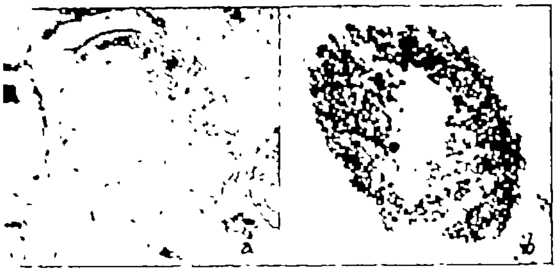

Fig. 2 Section through the Malpighian tubes of *Culex pipiens* treated with phosphorus-32. (*a*) 4th instar larvæ; (*b*) three-day old pupæ. Toluidine-blue stain

omparable with the granules in the Malpighian tubes f blowflies, which were analysed in detail by Waterouse[3].

The phosphorus-32 reaches the Malpighian tubes y way of the blood. This can be concluded from xperiments on animals in which the gut has ceased o show radioactivity. In spite of this absence of adioactivity in the gut, accumulation of phosphorus-2 occurs in the Malpighian cells; hence the phoshorus-32 could not have originated from the gut ontent, but must have been taken up from the lood.

able 1. AMOUNTS OF PHOSPHORUS-32 (AS A PERCENTAGE) WHICH AN BE EXTRACTED FROM ENTIRE ANIMALS (*Culex pipiens*) BY VARIOUS SOLVENTS

he animals lived in a solution containing phosphorus-32 for 24 hr. nd in normal tap water for 24 hr. before the extractions were made

| | Alcohol-ether | Perchloric acid (2%) | Perchloric acid (10%) | Residue |
|---|---|---|---|---|
| Early 4th instar larvæ | 35·4 | 22·4 | 28·8 | 13·4 |
| Late 4th instar larvæ | 29·4 | 41·1 | 24·1 | 5·4 |
| Young pupæ | 25·3 | 46·1 | 22·2 | 6·4 |
| Old pupæ | 24·7 | 45·3 | 21·6 | 8·4 |

The amount of acid-soluble phosphorus-32 in the nimals increases during metamorphosis (Table 1). his is in accordance with the quantitative determinaion of phosphate[4]. We have shown (unpublished xperiments) that it originates from the histolysed rgans (especially the gut) in which the synthesis f phosphorus-containing compounds rapidly declined nd the breakdown of these substances was accelrated. It seems that this increased level of inorganic hosphates in the blood is partially compensated for y the Malpighian tubes, which take up and store he phosphate. The conclusion is justified that the alpighian tubes are active in the regulation of hosphate balance in the animal, and take part in he processes of histolysis and histogenesis.

## Synthesis of (L) α-2,4-Dinitrophenylhistidine

THE reaction of histidine with 1 : 2 : 4-fluorodinitrobenzene (FDNB) could yield a di-substituted histidine and two mono-substituted histidines. Didinitrophenylhistidine has been prepared in pure form[1–4], and although the isolation of a monodinitrophenylhistidine has been claimed[1], neither physical constants nor proof of structure were given. Later workers have not been able to prepare either of the mono-substituted compounds in pure form[4,5]. Efforts to synthesize α-dinitrophenylhistidine were recently reported to have resulted in mixtures containing equal amounts of imidazole dinitrophenylhistidine and α-dinitrophenylhistidine[6].

The present synthesis of α-dinitrophenylhistidine was conceived as a result of chromatographic analysis (Fig. 1) of the products formed in the reaction between histidine and 1 : 2 : 4-fluorodinitrobenzene when the ratio of reagent to amino-acid was varied within wide limits. Examination of the chromatogram suggested that, with 0·5 mole of the fluorodinitrobenzene and 1·0 mole of histidine, only a mono-substituted compound was formed. With larger amounts of reagent this was transformed to the di-substituted compound; the transformation was complete when more than two moles of the reagent were present. The spot obtained with the lower concentration of fluorodinitrobenzene was ninhydrin-negative and reacted strongly positive to the Pauly diazo test. This indicated that the product was α-dinitrophenylhistidine, and suggested reaction conditions for its preparation.

Pure α-dinitrophenylhistidine was prepared as follows: 1·917 gm. (0·01 mole) of L-histidine monohydrochloride and 8·4 gm. of sodium bicarbonate were dissolved in 200 ml. of water, and 0·453 gm. (0·0025 mole) of 1 : 2 : 4-fluorodinitrobenzene in 25 ml. of ethanol was added with stirring. After 1 hr. at room temperature, the volume was reduced *in vacuo* to 50 ml., the *p*H adjusted to 6·5 by

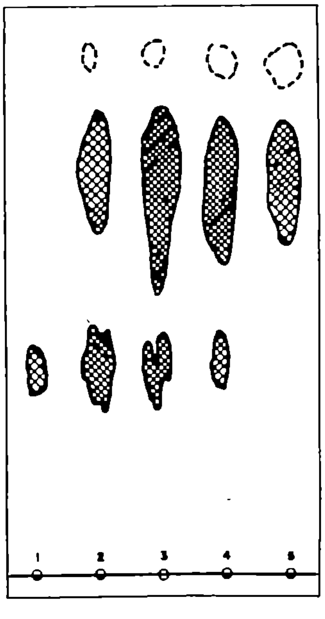

Fig. 1. Chromatogram of the yellow products resulting from the dinitrophenylation of 1 mole histidine for 3 hr. at room temperature with the following amounts of 1 : 2 : 4-fluorodinitrobenzene: (1) 0·5 mole; (2) 1·0 mole; (3) 1·5 mole; (4) 2·0 mole; (5) 2·5 mole

cautious addition of concentrated hydrochloric acid and the solution chilled to 5–10° C. The precipitate was removed by filtration and recrystallized from a minimum volume of dilute alcohol in water. The shiny yellow crystals obtained after 18 hr. in the cold were collected and dried *in vacuo* at 60° C.

Yield: 0 15 gm.
Melting point (uncorr.): 278–280° C. (decomp.).
Specific rotation: $[\alpha]_D^{25}$ − 100·0° (0 154 per cent, 4 *N* hydrochloric acid).
Analysis: found, C, 44 94; H, 3·405; N, 21·50 per cent; calculated for $C_{12}H_{11}O_6N_5$, C, 44 86; H, 3·45; N, 21·79 per cent.

The compound is ninhydrin-negative, indicating substitution of the α-amino group. The Pauly test[6] for the unsubstituted imidazole ring is strongly positive and, mole for mole, is of approximately the same intensity as given by histidine (Fig. 2). The absorption maximum for α-dinitrophenylhistidine in 92 per cent acetic acid is at 342·0 mμ, while that for the disubstituted compound is at 352·0 mμ. The material gives a single spot on paper chromatograms, with $R_F$ = 0·32 (in water-saturated butanol) and 0·43 (in butanol/formic acid/water; 75 : 15 : 10).

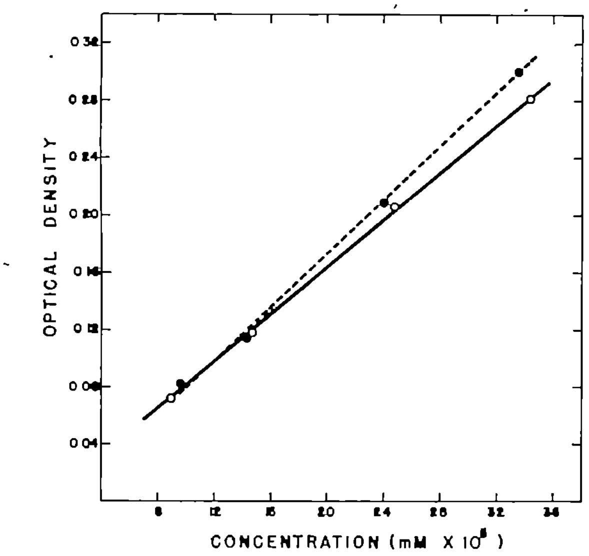

Fig. 2. Intensity of Pauly test for histidine and α-dinitrophenylhistidine. ○—○, Histidine; ●—●—, α-dinitrophenylhistidine

# Influence of Cortisone on Connective Tiss —Epithelial Relations in Wound Healin Hair Regeneration and the Pathogenesis Experimental Skin Cancers

Most investigators agree that cortisone retards t development and diminishes the ultimate inciden of experimentally induced skin cancers[1]. Boutw and Rusch[2] reported the induction of papilloma but not of carcinomata to be diminished by cortison Piccagli *et al.*[3] claimed to have increased inductic of tumours with methylcholanthrene by cortison These differences in opinion may perhaps be attribu able to variations in dosage, route and time administration of cortisone relative to the applicatic of carcinogens. This seems likely, since Baker[4], an we too, have shown that cortisone suppresses ha growth, while Andreasen and Engelbreth-Holn demonstrated that tumour incidence depends on th phase of the hair-cycle at the time of application the carcinogen.

We have studied the effects of cortisone on th histogenesis of wound healing in rabbits and on ha regeneration after plucking, and the pathogenes of tumours in mice treated with methylcholanthren special attention being devoted to epithelial – con nective tissue relations. We have found, *inter ali* that cortisone affects wound healing in rabbit primarily by depressing the activity of the connectiv tissue. Whereas, both in rabbits and in mice, cortison produces marked thinning of both dermis an epidermis, wounding in rabbits and plucking o hair and painting with methylcholanthrene in mic induce marked localized epithelial hyperplasia an regeneration even though connective tissue response are still suppressed. However, epithelial 'invasion of the new connective tissue (ultimately forme despite the action of cortisone) and 'pseudo-peg formation, described by us as a constant reactio in healing wounds[6], are suppressed by cortisone.

Local application of cortisone in mice, to an are previously depilated by plucking, completely inhibit hair regeneration in the treated area. This seems t be due to suppression of invasion of dermis by new epidermal *Anlagen* as well as to the apparen inability of cortisone-suppressed connective tissu to form new hair papillæ, despite the presenc of normal epidermal hyperplasia in the pluckec areas.

Cortisone injections fail to suppress epithelia thickening and keratinization localized to the are painted with methylcholanthrene in mice. However, dermal atrophy and loss of subcutaneous fat are marked in mice receiving cortisone injections, and invasion of dermis by healing epidermal spurs is distinctly suppressed. Macroscopically, hair regeneration and the incidence of papillomata and carcinomas are significantly depressed, although on microscopic examination we found that malignant change occurs within the epidermis of cortisone-treated mice. Consequently, numerous carcinomata *in situ*, comparable with Bowen's disease in man, were encountered microscopically in cortisone-treated mice, even when neoplasms were not detectable macroscopically. This accounts for the discrepancy between the macro- and microscopically determined incidence of tumours, and for the apparent delay, but not suppression, of carcinogenesis by cortisone.

Thus, in two separate and slightly differently designed experiments, papillomas occurred in seven-en of eighteen control methylcholanthrene-painted ice, and in only seven of the seventeen in the ethylcholanthrene plus cortisone group; the numbers papillomas averaged 6·5 per mouse in the former, mpared with 1·6 per mouse in the latter. Further- ore, macroscopically detectable carcinomas occurred fifteen of eighteen controls, and in only seven of venteen cortisone-treated mice. In one experiment, ten controls examined microscopically showed alignant tumours (as compared with nine out of n macroscopically), while in the cortisone group, ly three mice showed macroscopically observable alignancies, and eight of nine animals had micro- opically detectable carcinomata *in situ* which were uite unrelated to papillomas.

Thus, cortisone does not eliminate the epidermal sponse evoked by wounding, hair plucking or by eatment with methylcholanthrene. However, the ppression by cortisone of the usual connective-tissue sponses to these stimuli influences the histogenesis f wound healing, hair regeneration and tumour evelopment. Although the incidence of papillomas, nd the subsequent neoplasia in such benign tumours, diminished by cortisone, neoplasia within the pidermis itself is not eliminated. Thus, the patho- enesis and biology of these malignant tumours are istinctly altered.

Our histochemical findings, combined with in- ormation from the literature, indicate that cortisone eems to induce its effects by acting on the ribose ucleic acid and/or mucopolysaccharide metabolism f the dermis, thereby indirectly influencing epidermal esponses to various stimuli.

These findings show, in yet another way, the robable role of the dermis and of disturbed dermal– pidermal relations in the pathogenesis of skin umours, and suggest a new approach to the investiga- ion of the influence of steroid hormones on carcino- enesis.

The expenses incurred during this study were lefrayed primarily by a generous grant from the chlesinger Organization, South Africa. We wish o thank Mr. W. A. Michie of Ciba, Ltd., Mr. F. Vayne of British Drug Houses, Ltd., and especially Ir. A. M. Patt of Scherag, Ltd., for cortisone used n this study.

## Influence of Osmotic Pressure on the Polyamine Requirement of *Neisseria perflava* and *Pasteurella tularensis* for Growth in Defined Media

THE discovery by Herbst and Snell[1] that putrescine or related di- and poly-amines constitute an essential growth requirement for *Haemophilus parainfluenzae* assigned for the first time a biological function to these substances, known to be of wide occurrence in Nature[2]. Afterwards, putrescine was recognized as an indispensable growth factor for *Neisseria perflava*[3] and a stimulatory agent for *Pasteurella tularensis*[4]. The aim of the present communication is to describe an interrelationship observed between the tonicity of the medium and the polyamine requirement. This observation seems to throw light on the mechanism of the growth-promoting action of these compounds.

Nemes, Pelczar and Doetsch[5] reported that *N. perflava* can be cultivated in a semi-synthetic medium composed of a vitamin-free acid-hydrolysate of casein, salts and biotin. Later, Martin, Pelczar and Hansen[3] found an additional demand of the organism for either putrescine or some other related polyamine, on replacing casein hydrolysate in the above medium by a mixture of eighteen amino-acids.

These results have been fully confirmed by us with two strains of *N. perflava*. The ability of the micro-organism to dispense with putrescine in a medium prepared from a commercial acid-hydrolysate of casein ('Casamino-acids', Difco) suggested the possibility that the hydrolysate might contain, as a natural contaminant, sufficient amounts of an active polyamine not removable by the treatment employed for the preparation of the vitamin-free product. However, this was scarcely compatible with the finding that a tryptic digest of casein did not sustain growth unless supplemented with microgram quantities of either putrescine or spermine. A similar result was obtained with a 'salt-free' casein hydrolysate prepared by digestion with sulphuric acid followed by neutralization with barium hydroxide.

As the commercial hydrolysate was known to contain about 40 per cent sodium chloride, a possible effect of the latter substance was suspected. In fact, an ashed sample of 'Casamino-acids' was found to retain all the activity of the original preparation. Moreover, addition of graded amounts of sodium chloride to the defined medium of Martin *et al.*[3] or to an enzymatic casein digest produced, up to a certain concentration, nearly proportional growth responses. The maximal response was, however, somewhat inferior to that obtained with optimal amounts of putrescine. Sodium chloride could be successfully replaced not only by other salts of the alkaline series (potassium, lithium) but also by certain non-electrolytes (glucose, sucrose) (see Table 1). The optimal range of activity corresponded roughly to salt concentrations isotonic with $0{\cdot}1\,M - 0{\cdot}15\,M$ sodium chloride. With non-electrolytes the onset of growth was usually delayed, but the final yield was nearly as good as with sodium chloride. Maximal growth with glucose or sucrose was achieved at concentrations close to $0{\cdot}1\,M$.

In the light of the above results, it appeared interesting to see whether a similar interdependence between the tonicity of the medium and the polyamine requirement can be demonstrated with strains of *P. tularensis* which, as previously shown, require both sodium and spermine for optimal growth[4]. With strain 176, it was found that sodium chloride and

| Spermine, 10 μgm./ml. | 68 | 36 |
| Sodium chloride, 0·1 *M* | 40 | 30 |
| Sodium chloride, 0·15 *M* + spermine, 10 μgm./ml. | 68 | 70 |
| Potassium chloride, 0·19 *M* | 50 | 32 |
| Glucose, 0·1 *M* | 31 | 25 |
| Sucrose, 0·1 *M* | 38 | 28 |
| Mannitol, 0·1 *M* | 2 | 27 |

spermine could be substituted for each other to a large extent, though maximal rate of proliferation was obtained only when both factors acted in combination (Table 1). Here, too, the growth-enhancing effect of sodium chloride could be duplicated by other salts as well as by non-electrolytes.

In the course of this work, it was observed that washing *P. tularensis* cells with distilled water instead of the usual saline resulted in a decrease of their viability as shown by prolongation of the lag phase or even by complete suppression of multiplication. This deterioration could be prevented by adding some micrograms of spermine to the distilled water used for washing. Thus, in this respect again, sodium chloride and spermine proved to be interchangeable.

The results presented so far seem to justify the general conclusion that both the osmotic agents and the polyamines control, each independently and by a different mechanism, some definite cell function essential for growth. It appears likely that this vital function may be related to permeability of the cell membrane; no conclusion as to the exact mechanism involved is yet possible.

## Systematic Position of the Euphausiacea

ELSEWHERE in this issue of *Nature* (see p. 911) I have mentioned that, although the idea originated with Kemp, Gurney was the first to place the Euphausiacea in the order Decapoda, which he divided into two suborders, Euphausiacea and Eudecapoda. Gurney never intended to include the Euphausiacea in his Ray Society monograph, "Larvae of Decapod Crustacea" (1942)—Euphausid literature is omitted from the earlier companion volume, "Bibliography of the Larvae of Decapod Crustacea" (1939)—but a chance remark of mine prompted him to do so when his manuscript was almost, or quite, finished. This resulted in some inconsistency of treatment of the Euphausiacea, partly because he sometimes omitted to alter 'Decapoda' to 'Eudec poda' where necessary, partly because he had alrea mentioned the Euphausiacea (as an independe order) here and there, in the same way as he mentio the Stomatopoda, for example. He did not expla why he altered the classification; Kemp's idea w quite new to him and he doubtless misundersto what I said. That he had not considered the matt carefully is proved by the letter which he sent me 1949 after we had again discussed the systemat position of the Euphausiacea (see p. 911 for h suggested solution, which has much in its favou Incidentally, Nakazawa's claim, referred to l Gurney[1], that an economically important Japane species of *Sergestes* has a free nauplius larva is soun Recently I had the relevant passage translated Nakazawa collected sixty eggs on August 6, from th fishing grounds, and from these he obtained the thr naupliar stages which he figured; eighteen of th third-stage nauplii metamorphosed to the first-sta protozoea, which is an undoubted Sergestid larva.

All carcinologists would, I think, agree that th general classification of the Decapoda is in urge need of revision. According to Gurney (ref. 1, p. 11 "the four main difficulties in framing a satisfactor system for the Decapoda are: (i) relation of th Euphausiacea to the Decapoda; (ii) relation of th Penaeidea to the Caridea; (iii) position of th Stenopidea and of the Thalassinidea; (iv) relation the Dromiacea to the Brachyura"; and there a others. On embryological grounds, Gurney altered th position not only of Euphausiacea but also of Sten opidea, Thalassinidea and Dromiacea. Moreover, h maintains that the Thalassinidea is not homogeneou but comprises a homarine and an anomuran grou It would be interesting to follow this up with referenc to adult morphology, to see whether or not Gurney' views can be substantiated. In a forthcoming pape I hope to discuss more fully the systematic positio of the Euphausiacea; as I also intend to conside the relationships of the Dromiacea and of the Gymno pleura, and perhaps of other groups as well, it ma be some time before the work is finished. Meantim I would welcome any suggestions or comments tha may occur to other specialists.

## *Chainia*, a New Genus of the Actinomycetale

AN actinomycete isolated from soil in Poon showed on examination characters representing a undescribed genus. The species was saprophytic aerobic and mesophilic, growing readily on the variou nutrient agar media employed. The colonies o glucose–peptone agar are faint cream-yellow in earl stages, with well-developed fine non-septate mycelium 0·4–0·8μ in diameter and branching in a monopodia type. The hyphae developing in a radiating manne grow into the substrate, giving a lichenoid appear ance. There is no true aerial mycelium formed though growth at later period appears compact an raised. The unseptate mycelium never fragments int bacillary or coccoid forms and is Gram-positive an non-acid fast.

The chief distinguishing character of the genus i the formation of spherical sclerotic granules in larg

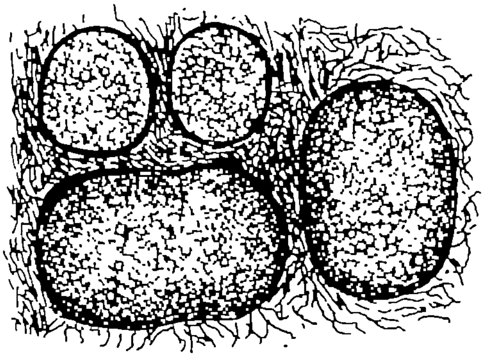

Fig. 1. Sclerotic granules in *C. antibiotica*. × 500

gregate masses from the mycelium (Fig. 1). In eir formation, closely septate hyphæ thickened up 1·5μ, incurl and become compacted to form hard lerotic granules ranging from 16 to 75μ in ameter. There is an enveloping layer of mycelium, in some cases several small granules become closed in a common mycelial sheath. In old colonies, e granules become readily separated from the getative mycelium and on transferring to fresh edia germinate and develop into new colonies.

Comparative studies indicated that the occurrence f a branching non-septate mycelium without true erial mycelial formation shows affinity with *Micro-onospora* Orskov, but lacks the characteristic single ores produced in the latter genus. The type of lerotic granules resemble in a general way those resent in *Actinomyces bovis* Harz. and *A. israeli* Kruse) Lachner-Sandoval, which incite actinomycoses higher animals[2]. The granules in the *Actinomyces* pecies mentioned above are structurally different, ith radiating 'clubs'. Further, the genus *Actinomyces* arz (*sensu* Waksman and Henrici[1]) has a vegetative mycelium fragmenting into bacillary or coccoid orms, and is mainly anaerobic to microaerophilic. n contrast, the species under study has a true ycelium as in Streptomycetaceae and is aerobic nd mesophilic. These characters indicate that the pecies under study represents an undescribed genus, or which the name *Chainia* is proposed, in honour f Prof. E. B. Chain, of the Istituto Superiore Sanità, ome.

*Chainia* Thirumalachar *gen. nov.*: mycelium well eveloped, fine, non-septate, growing into substrate, ot forming true aerial mycelium, non-fragmenting, ram-positive, non-acid fast, deeloping sclerotic granules comosed-of incurled hyphal cells, single r in aggregates, enveloped in yphal sheath at first and later ecoming free. Conidial form unnown. Type species: *Chainia ntibiotica* Thirum., isolated from oil, Poona, India.

Studies on antibiotic activity ave indicated that *C. antibiotica* roduces a very powerful antifungal ubstance both on agar plates and n agitated submerged cultures in hake flasks. While the nature of he substance is under test, the eneral antibiotic spectra indicated n agar streak tests is given in able 1. A fragment of mycelium f *C. antibiotica* 2 mm. in diameter was inoculated on glucose peptone agar for five days in Petri dishes (10 cm. diam. with 20 c.c. of medium), incubated at 24° C. and tested for antifungal or antibacterial activity.

Table 1

| Name of organism tested | Diam of zone of inhibition |
|---|---|
| *Cryptococcus neoformans* | 70 mm. |
| *Sporotrichum schenkii* | 50 mm |
| *Microsporum audouini* | 50 mm. |
| *Saccharomyces* sp. | 60 mm. |
| *Curvularia lunata* | 60 mm. |
| *Penicillium chrysogenum* | 50 mm. |
| *Botryodiplodia phaseoli* | 45 mm. |
| *Bacillus subtilis* | 40 mm. |
| *Micrococcus pyogenes* var. *aureus* | 45 mm. |
| *Escherichia coli* | Nil |

Detailed accounts of the description of the species and genus, biochemical and antibiotic activities will be published separately.

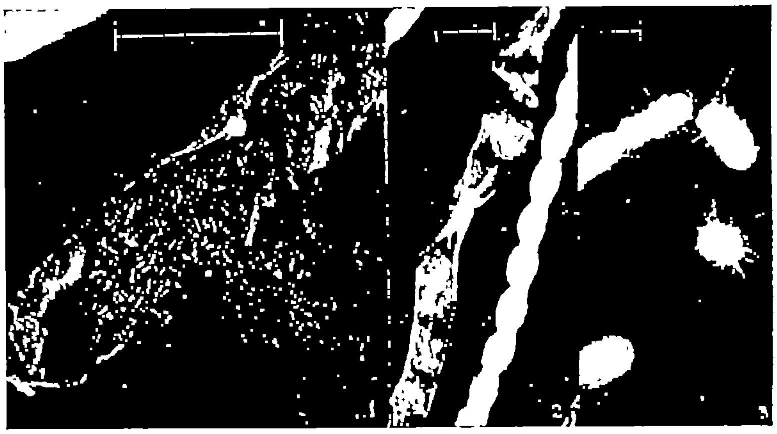
## Spore Formation in the Genus *Streptomyces*

In the course of a study of the Streptomycetes present in New Zealand soils, the electron microscope revealed certain details of spore formation which may be of interest.

Micrographs of a number of named cultures as well as of freshly isolated material give support to the views expressed so far back as 1898 by Lachner-Sandoval[1].

Spore formation takes place within the hyphal wall. The contents divide into fragments which are separated by less dense partitions, having the appearance of septa. The fragments are somewhat irregular in size and divisions appear to occur simultaneously along the hypha.

The spores remain in chains, held together by the sheath-like hyphal wall. As the spores mature, the nature of the sheath appears to undergo change. In some strains it persists, the spores being liberated by means of a longitudinal split, and the old wall is seen as a ribbon-like sheath. The sheath may have cross markings that show clearly the positions of the spores it formerly enveloped (Fig. 2). In other strains



Scale length 1 μ

the sheath disintegrates readily and small fragments only remain to indicate its presence.

Micrographs of the sheath show a definite structure. Narrow pointed plates lie side by side in groups at various angles, the whole presenting a more or less regular pattern as if crystalline (Fig. 1). The persistence of the sheath seems to be associated with the degree of marking. The most strongly patterned sheaths observed were those which broke up readily, apparently fragmenting parallel to the long axes of the narrow plates.

Using the technique of Erikson[2], the sheath did not stain with sudan IV.

Attached to the sheath and sometimes enfolded by it, small dense spherical bodies were frequently observed. These inclusions varied in size from 0·1μ to 0·2μ. The nature and function of these bodies are not known (Fig. 1). Electron micrographs of *Nocardia ruber*[3] show granules which may be similar.

The presence of spiny processes on the spores of certain strains was reported by Flaig *et al.*[4], and several isolates from New Zealand soils have been noted to produce spores with spiny outgrowths. Micrographs show that spores with spines are produced within the hyphal wall in the normal manner, and are liberated by a longitudinal splitting of the sheath. The sheath shows clearly markings and indentations caused by the spines. In some cases the spines were observed to penetrate the hyphal wall and occasionally were broken off when the spores were released.

As no previous record has been seen, it is of interest to note that a culture of *S. flaveolus* NRRL. B.1334 showed spiny spores. The spines on the spores of *S. flaveolus* are long and thin (1μ × 0·04μ) tapering only slightly towards the tip. They are very fragile and easily broken off (Fig. 3).

I am indebted to Mr. K. I. Williamson and Mr. W. Bertaud of the Dominion Physical Laboratory for the electron micrographs.

## Isolation of *Microsporum gypseum* and of *Keratinomyces ajelloi* from Australian Soil

SIXTY-SIX samples of soil collected from various parts of New South Wales were examined for the presence of keratinophilic fungi. Following the technique of Vanbreuseghem[1], Petri dishes half-filled with moistened soil were baited with autoclaved human hair. At varying intervals, ranging from three to seven weeks, some hairs were found to be overgrown by fungi; these were examined microscopically and transferred to Sabouraud's agar containing 'Actidione' (cycloheximide), penicillin and streptomycin[2].

*Microsporum gypseum* was isolated in pure culture from five samples of soil and *Keratinomyces ajelloi* from eight samples. So far as we know, this is the first occasion on which these fungi have been isolated from Australian soil. Other fungi are being encountered in the course of this work, which is supported by a grant from the National Health a Medical Research Council of Australia and wh will be reported in full later.

## Selection of Aphid Species by Different Kinds of Insect Traps

MOERICKE yellow trays are a simple and che method of trapping aphids, and are being wide used for the study of aphid flight and behavio These traps, however, have never been standardiz with respect to their differential catch of vario species. Three yellow trays and a suction trap we operated close to each other, over a small plot pyrethrum not infested with aphids, for more th two years at the East African Agriculture a Forestry Research Organization, near Kikuy Kenya. There are reasons for thinking that t suction trap takes a fairly accurate sample of aph density. The ratio of yellow-tray to suction-tr catch for the commoner species is shown in Table The total number of specimens, from both traps, placed in parentheses. All the specimens listed we alate viviparous females except for the male *Rhopal siphum maidis*.

Table 1. RATIO OF CATCHES IN YELLOW TRAYS TO THOSE BY SUCTIO TRAP

| | | | |
|---|---|---|---|
| 1 | *Toxoptera citricidus* | 30·7 | (95) |
| 2 | *Myzus ornatus* | 25·0 | (52) |
| 3 | *Macrosiphum euphorbiae* | 14·7 | (771) |
| 4 | *Hyadaphis coriandri* | 12·7 | (41) |
| 5 | *Brevicoryne brassicae* | 11·1 | (799) |
| 6 | *Brachycaudus helichrysi* | 9·5 | (21) |
| 7 | *Trifidaphis phaseoli* | 9·5 | (21) |
| 8 | *Myzus persicae* | 6·4 | (844) |
| 9 | *Aphis* spp. | 3·3 | (2,048) |
| 10 | *Hyperomyzus lactucae* | 2·9 | (37) |
| 11 | *Lipaphis erysimi* | 2·7 | (720) |
| 12 | *Longiunguis sacchari* | 2·7 | (76) |
| 13 | *Dactynotus compositae* | 2·2 | (305) |
| 14 | *Aulacorthum vincae* | 2·1 | (49) |
| 15 | *Geoica lucifuga* | 2·1 | (25) |
| 16 | *Rhopalosiphum maidis* ♂♂ | 2·0 | (51) |
| 17 | *Tetraneura hirsuta* | 1·6 | (102) |
| 18 | *Aploneura lentisci* | 1·5 | (168) |
| 19 | *Rhopalosiphum splendens* | 1·3 | (734) |
| 20 | *Micromyzus agavi* | 1·2 | (35) |
| 21 | *Macrosiphum* (*Sitobion*) spp. | 0·8 | (261) |
| 22 | *Rhopalosiphum maidis* ♀♀ | 0·8 | (972) |
| 23 | *Schizaphis cyperi* | 0·6 | (344) |
| 24 | *Acyrthosiphon pisum* | 0·5 | (414) |

From these figures it is evident that some specie may be selected as much as thirty times as strongl as others by yellow trays than by suction trap The host plants of species 1–11, 13 and 14 and 2 are dicotyledons, and of 12 and 15–23 are grass or sedges. These grass- and sedge-feeding specie belong to several different taxonomic groups, an the yellow trays select against them in favour of mos of the common species feeding on dicotyledons.

Statistical analysis of these trap catches from hou to hour shows that the presence of sunshine increase the yellow-tray catch relative to the suction trap these findings are to be published in greater deta elsewhere.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, November 14

nstitute of Metal Finishing (in the Thames Room, Charing ss Hotel, London, W.C.2), at 11 a.m.—Annual General Meeting. 3 p.m.—Mr. R. A. F. Hammond: "Research and Industrial plication in Metal Finishing" (Presidential Address).

Royal Geographical Society (at 1 Kensington Gore, London, V.7), at 5 p.m.—Mr. R. A. Hamilton and others: "Scientific search by the North Greenland Expedition".

British Society for the History of Science, Philosophy of ence Group (in the Joint Staff Common Room, University College, wer Street, London, W.C.1), at 5.30 p.m.—Dr. H. Ezriel: "The e of Psychoanalytic Sessions as Experimental Situations".

Institution of Electrical Engineers (at Savoy Place, London, .C.2), at 5.30 p.m.—Discussion on "Is the Engineer Broad Enough his Outlook?". Opening Speaker: Dr. P. Dunsheath.

University of London (in the Physiology Theatre, University llege, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. S. ldberg, F.R.S.: "Recent Experiments on the Pharmacology of e Periventricular Grey Matter of the Brain".*

Royal Institute of Chemistry, London Section (joint meeting th the Woolwich Polytechnic Scientific Society, at the Woolwich lytechnic, London, S.E.18), at 7.30 p.m.—Dr. T. V. Arden: "Ion change Resins".

## Tuesday, November 15

Institution of Chemical Engineers (at the Geological Society, rlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. F. H. lams and Mr. A. G. Baker: "An Assessment of Dry-Blending quipment".

Institution of Electrical Engineers, Measurement Section oint meeting with the Radio Section, at Savoy Place, London, .C.2), at 5.30 p.m.—Dr. D. L. Holloway: "An Electrolytic-Tank quipment for the Determination of Electron Trajectories, Potential d Gradient" and "A Method of Tracing Electron Trajectories in osed Electric and Magnetic Fields" (Papers to be read by Dr. J. H. estcott).

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, eppel Street, London, W.C.1), at 5.30 p.m.—Prof. R. H. Tunbridge: Observations on the Structure of Connective Tissue Fibres". (Sixth fifteen Lectures on "The Scientific Basis of Medicine".)*

Royal Aeronautical Society (at 4 Hamilton Place, London, .1), at 7 p.m.—Sir Ronald A. Fisher, F.R.S.: "The Planning of xperiments".

## Wednesday, November 16

Royal Microscopical Society, Industrial Section (at the ritish Pharmaceutical Society, 17 Bloomsbury Square, London, .C.1), at 2 p.m.—Exhibition and Symposium on "Fibre Microopy".

University of London (at the Postgraduate Medical School of ondon, Ducane Road, London, W.12), at 2 p.m.—Dr. G. Popjak: Fat Metabolism".*

Royal Meteorological Society (at 49 Cromwell Road, London, .W.7), at 5 p.m.—Mr. Joanne Malkus: "The Effects of a Large land Upon the Trade-Wind Stream"; Mr. R. P. Pearce: "The alculation of a Sea Breeze Circulation in Terms of the Differential eating Across the Coast-line"; Mr. R. C. Smith: "Theory of Airow Over a Heated Land Mass".*

Royal Statistical Society (at the London School of Hygiene nd Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—r. D. J. Finney: "The Statistician and the Planning of Field xperiments".

Eugenics Society (in the Rooms of the Royal Society, Burlington ouse, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. C. Maurice illiams: "Problem Families in Southampton".*

Research Defence Society (in the Physiology Lecture Theatre, niversity College, Gower Street, London, W.C.1), at 5.30 p.m.—ir Henry Dale, F.R.S.: "Humanity's Rising Debt to Medical esearch" (Twenty-fourth Stephen Paget Memorial Lecture).

Aslib (at the Royal Society of Arts, 8 John Adam Street, Adelphi, ondon, W.C.2), at 6 p.m.—Dr. E. J. Crane: "The Chemical Abstracts ervice and its Plans".

Iron and Steel Institute (at the Seymour Hall, Seymour Place, ondon, W.1), at 6 p.m.—Sir Robert Shone and Mr. W. F. Cartwright: 'The Russian Iron and Steel Industry".

Royal Institute of Chemistry, London Section (at the Institute f Metals, Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Annual eneral Meeting. Dr. D. W. Kent-Jones: "A Progressive Institute".

Polarographic Society (at the Royal Institution, Albemarle treet, London, W.1), at 7.30 p.m.—Prof. J. Heyrovsky (Czechoslovakia): Presidential Address.*

## Thursday, November 17

Royal Aeronautical Society (at the Institution of Civil ngineers, Great George Street, London, S.W.1), at 10 a.m.—Meeting n "Aircraft Design Philosophy"; Dr. P. B. Walker: "Structural esting"; Mr. H. Giddings: "Fatigue"; Mr. C. F. Joy: "Flight oads"; Mr. J. K. Williams: "Safety Factors".

University College London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. Kenneth Garside: "The Arrangement of Books: a New System of Classification in the College Library".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. R. A. Smith: "Physics at the Radar Research Establishment, Malvern".

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. F. Kingdon-Ward: "Travels in the Great Forest Belt of North Burma".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting. Prof. J. H. C. Whitehead: "Duality in Topology" (Presidential Address).

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr R. J. P. Williams: "Metal Complexes as Models for Metallo-Enzymes". (Further Lectures on November 24, December 1 and 8.)*

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall of the Junior Institution of Engineers, Pepys House, 14 Rochester Row, London, S.W.1), at 6 p.m.—Mr. K. H. Clare and Mr. P. T. Sherwood: "Organic Matter in Soil in Relation to Soil–Cement Stabilization".

Oil and Colour Chemists' Association (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. H. M. Evans: "Recent Developments in Polyester Resins".

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m.—Prof. D. H. Everett: "Some Developments in the Study of Physical Adsorption" (Tilden Lecture).

Royal Society of Tropical Medicine and Hygiene (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 7.30 p.m.—Laboratory Meeting.

## Friday, November 18

Society of Chemical Industry, Corrosion Group (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 10 a.m.—Symposium on "The Protection of Cable Sheathing".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. C. F. A. Pantin, F.R.S.: "The Primitive Nervous System".

## Friday, November 18—Saturday, November 19

Institute of Physics, X-Ray Analysis Group (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1)—Autumn Conference—"Semi- and Non-Crystalline Materials".

## Saturday, November 19

Biochemical Society (at the Middlesex Hospital Medical School, Mortimer Street, London, W.1), at 11 a.m.—Scientific Papers.

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. F. N. Ghadially: "Fish, Reptiles and Amphibians".*

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Training Officer (with an honours degree in chemistry and physics or corporate member of a senior Engineering Institution, or equivalent qualifications, with some years' experience in industry and knowledge of industrial training methods) at the Industrial Group Headquarters, United Kingdom Atomic Energy Authority, Risley, to take part in the preparation and administration of training courses, and to assist the Chief Training Officer (Operations)—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, quoting 1160 (November 18).

Assistant Experimental Officers (2) (with at least G.C.E. to advanced level in biology, or equivalent qualification, preferably with a degree in biology), at the Merlewood Research Station, Grange-over-Sands, for laboratory work, including microscopical examination and fine manipulation, on microarthropods or nematodes, and some field work—Establishment Officer, The Nature Conservancy, 19 Belgrave Square, London, S.W.1 (November 19).

Head, Grade II (with high academic or professional qualifications and considerable full-time teaching experience, preferably with industrial, research or administrative experience), of the Department of Chemistry and Biology—The Principal, Norwood Technical College, Knight's Hill, London, S.E.27 (November 19).

Lecturer in Electrical Engineering—The Registrar, Queen Mary College, Mile End Road, London, E.1 (November 19).

Lecturer in Social Philosophy—The Secretary, The Queen's University, Belfast (November 19).

Research Assistant (with a good honours degree in chemistry) in the Department of Chemistry, to work under direction on a project involving radiochemical techniques—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (November 19).

**Senior Lecturer** (with qualifications and experience necessary to plan and supervise the teaching of physical chemistry up to honours degree standard) in Physical Chemistry—The Principal, Royal Technical College, Salford 5 (November 19).

**Statisticians** (with a first- or second-class honours degree, or equivalent, in statistics, mathematics, economics or other appropriate subject, or with examinations of approved statistical society) at the Central African Statistical Office, Ministry of Finance, Federation of Rhodesia and Nyasaland—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (November 19).

**Professor of Mechanical Engineering** at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 24).

**Scientific Officer** (with first- or second-class honours degree in chemistry) at the Northern Outfall Works, Beckton, London, for scientific control and development duties—The Medical Officer of Health (PH/D1), County Hall, London, S.E.1 (November 25).

**Lecturer** (with an honours degree and research experience) in Physics, at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 28).

**Deputy Conservation Officer** (graduate in biological science, agriculture or forestry, with some administrative experience, or equivalent qualifications), with the Nature Conservancy in Wales, for duties including the investigation of wild life conservation problems, contacts with Natural History Societies, landowners, local authorities and government departments; co-operation with research scientists and others on management of Nature Reserves—The Establishment Officer, The Nature Conservancy, 19 Belgrave Square, London, S.W.1 (November 30).

**Lecturer** (with an honours degree in zoology, and preferably a special knowledge of agricultural entomology, with research and teaching experience of this subject) in Agricultural Entomology—The Secretary, School of Agriculture, Downing Street, Cambridge (November 30).

**Lecturer** (graduate, with special interest in surveying) in Civil Engineering—The Registrar, King's College, Strand, London, W.C.2 (November 30).

**Physiologist in the Department of Physiology and Plant Culture**, to work on plant response to environment—The Secretary, John Innes Horticultural Institution, Bayfordbury, Herts (November 30).

**Professor of Parasitology** and **Professor of Bacteriology** at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 30).

**Demonstrator** (honours graduate in chemistry) in Chemistry—The Registrar, College of Technology, Manchester 1 (December 1).

**Assistant Experimental Officers** or **Experimental Officers** (preferably with a degree in natural sciences or engineering, with statistics) for the Scientific Adviser's Branch, Air Ministry, London, for duties including control of field studies and analysis of data relating to operation of military aircraft, including technical supply problems, logistics and flying safety—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.392/5A (December 3).

**Lecturer in Animal Production**, and **Lecturers (2) in Crop Production**, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1 (December 6).

**Senior Lecturer** (with a research degree in organic chemistry and experience of teaching this subject) in Organic Chemistry at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (December 9).

**Research Fellow** (with experience in low energy nuclear physics or photo disintegration problems) in the Department of Nuclear Physics, Research School of Physical Sciences, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 30).

**Lecturer** (with an honours degree and practical experience in public works engineering) in Civil Engineering—The Registrar, The University, Leeds 2 (January 2).

**Agricultural Engineer** (with a university degree in agriculture or engineering and postgraduate training in agricultural engineering) in British Guiana, to be responsible for the general improvement of local practices relating to agricultural engineering, to test and develop new techniques and mechanical devices for field and factory, and to train persons in the care and maintenance of farm machinery—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.63/30/05.

**Chemists** and **Biochemists** (with a good honours degree and preferably some research experience) for research on microbiological methods of analyses and the chemistry of cereal lipids—The Director, Research Association of British Flour-Millers, Cereals Research Station, Old London Road, St. Albans.

**Demonstrator** (graduate in economics, agriculture or geography) in Agricultural Economics, for research and teaching duties—The Secretary, Institute for Research in Agricultural Economics, Parks Road, Oxford.

**Mathematician**, Principal or Senior Scientific Officer grade (with a first- or second-class honours degree, or equivalent qualification, in applied mathematics and considerable experience in formulation and solution of advanced mathematical problems), at the Ministry of Supply, Armament Research and Development Establishment, near Sevenoaks, Kent, to lead a mathematical team in advanced basic research in either mechanics of fluids, steady and unsteady compressible flow, or of solids, elasticity, plasticity and fracture—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.391/5A (November 26).

**Physical Metallurgist** (with a university degree, or equivalent qualification, and preferably with some postgraduate research experience) for the British Iron and Steel Research Association, Sheffield, to work in a research group concerned with measurements of fundamental properties of iron and steel—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W quoting M.G.1.

**Scientific Officer** (with a good honours degree and an inter in biological problems, preferably with research experience) in t Department of Chemistry, to take part in researches on the che istry of milk proteins and enzymes—The Secretary, National Instit for Research in Dairying, Shinfield, Reading, Berks, quoting 55/19

# REPORTS and other PUBLICATION

*(not included in the monthly Books Supplement)*

## Great Britain and Ireland

The British University System 1914–1954. By Sir Hector Hetheri ton. (The P. J. Anderson Memorial Lecture, 1954.) (Aberdeen Univ sity Studies No. 33.) Pp. 18. (Edinburgh and London: Oliver a Boyd, Ltd., 1955. Published for the University of Aberdeen.) 1s. [1

Annals of the Cape Observatory. Vol. 18: Cape Photograp Catalogue for 1950.0. Zone −35° to −40°. Prepared under t directions of Dr. J. Jackson and R. H. Stoy. Pp. xii+260. (Londo H.M. Stationery Office, 1955.) 30s. net. [1

Report of the Conference on Industry and Technical Educatio (Organized by the Regional Advisory Council for the Organization Further Education in the East Midlands and the F.B.I. North Mi land Regional Council, and held at the College of Technology, Loug borough, 21 April 1955.) Pp. iii+41. (London: Federation of Brit Industries, 1955.) 4s. [1

Report of a Sub-committee on University Entrance Requiremen Pp. 20. (London: Committee of Vice-Chancellors and Principals the Universities of the United Kingdom, 1955.) [2

Science Museum. Classified Lists of Historical Events. Mechani and Electrical Engineering, including Energy Conversion, Tra mission and Storage; Atomic Energy; Pumping; Blowing a Compressing Machinery; Explosives and Ordnance. Compiled G. F. Westcott. Pp. iv+40. (London: H.M. Stationery Office, 1955 2s. net. [22

Peaceful Uses of Atomic Energy. Pp. 16. (London: Association Scientific Workers, and the Labour Research Department, 1955 6d. [22

Empire Cotton Growing Corporation. Progress Reports from Expe ment Stations, Season 1953–54. Queensland. By R. W. Peter Pp. 16. 9d. Survey of Reports. By J. B. Hutchinson. Pp. 14. 9 (London: Empire Cotton Growing Corporation, 1955.) [22

Technical Survey of the Copper Development Association. No. July, 1955. Pp. 36. (Radlett: Copper Development Associatio 1955.) [22

Air Ministry: Meteorological Office. British Rainfall 1953: Repo on the Distribution of Rain in space and time over Great Britain a Northern Ireland during the year 1953 as recorded by about 5,0 observers. (The Ninety-third Annual Volume of the British Rainf Organization.) Pp. iv+219. (M.O. 588.) (London: H.M. Stationer Office, 1955.) 25s. net. [22

## Other Countries

World Health Organization. Technical Report Series. No. 92 Joint ILO/WHO Committee on the Hygiene of Seafarers. Secon Report. Pp. 20. 1 Swiss franc; 1s. 9d.; 0.30 dollars. No. 93: Expe Committee on Midwifery Training. First Report. Pp. 21. 1 Swi franc; 1s. 9d.; 0.30 dollars. No. 96: Expert Committee on Biologic Standardization. Eighth Report. Pp. 19. 1 Swiss franc; 1s. 9d. 0.30 dollars. No. 98: Legislation Affecting Psychiatric Treatment Fourth Report of the Expert Committee on Mental Health. Pp. 25 1 Swiss franc; 1s. 9d.; 0.30 dollars. Monograph Series. No. 27 Chemotherapy of Malaria. By Sir Gordon Covell, Dr. Robert Coatney Dr. John W. Field and Dr. Jaswant Singh. Pp. 123. 10 Swiss francs 17s. 6d.; 3.25 dollars. (Geneva: World Health Organization; London H.M. Stationery Office, 1955.) [22

United States Department of Agriculture. Leaflet No. 386: Mos quitoes: How to Control Them on Your Property. Pp. 8. 5 cents Leaflet No. 388: Horn Flies on Cattle: How to Control Them. Pp. 6 5 cents. Circular No. 957: Investigations of the Pink Bollworm and Hemipterous Cotton Insects. By L. W. Noble. Pp. 16. 10 cents Farmers' Bulletin No. 2084: The European Corn Borer and Its Con trol. Pp. 20. 15 cents. Home and Garden Bulletin No. 46. Insects and Diseases of Vegetables in the Home Garden. By L. B. Reed and S. P. Doolittle. Pp. 64. 25 cents. Picture Sheet No. 21: Pink Boll worm. Pp. 2. 5 cents. (Washington, D.C.: Government Printin Office, 1955.) [22

University of California Publications in Botany. Vol. 28, No. 1. A Study of Half-Chromatid Fragments in Meiosis of the Hybrid Bromus Trinii × B. Maritimus. By Marta Sherman Walters. Pp. 18+2 plates. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1955.) 35 cents. [228

# SCIENTIFIC BOOKS AND PAPERS

HE paper entitled "The Tower of Babel: the Language Barrier in Science" which Mr. B. C. kery presented before the Library Association at annual conference at Southport on September 22 ls with some aspects of the communication of owledge and ideas with which the scientist is ticularly concerned. Mr. Vickery discussed more ticularly the difficulties which language differences ate in communication between scientists; and his servations on the question of translations, made m the point of view of one who is librarian in the ers Research Laboratories of Imperial Chemical lustries, Ltd., deserve the attention of the research rker and technologist quite as much as that of the rarian. Moreover, some comments on the multicity of scientific and technical periodicals have turbing implications for the scientist and techlogist as well as for the librarian.

Mr. Vickery approaches the whole subject with the m purpose of attempting to remedy the inadeacies of modern methods of communication by the nted word, and not the least merit of an admirable rvey is that he sets his problem in the context of lucid historical survey, which incidentally disposes any claim for French as the major medium of mmunication at any time in the scientific world. e starts, however, by referring to a protest made Dr. Ancel Keys some five years ago in *Science* on e appearance of a periodical, the *Acta Physiologica lonica*, written entirely in Polish. This represented break with the pre-war practice of the Central ropean countries of providing summaries in rman, French or English when the text of the pers appeared in a minor language. The protest inted out that in modern times the overwhelming ajority of scientific work is published in English, rench and German, with an increasing proportion Russian, and to a lesser extent in Italian and anish. This protest brought a reply that to require inority linguistic groups to publish in languages her than their own would be to handicap whole ations of scientists, and it was argued that the real fficulty was that all countries are publishing in so any varied languages. Dr. J. E. Holmstrom has timated that about fifty per cent of the world's ientific papers are written in English, about fifteen r cent each in French and in German, perhaps ten r cent in Russian, while the remaining ten per cent are ublished in other languages, including two to three r cent in Spanish. That estimate alone sufficiently lustrates the unrealistic character of the reply to r. Keys's protest, nor is that comment substantially fected if Mr. Vickery is correct in his assumption at the situation is likely to get worse. The proortion of scientific periodicals published in Russian as probably doubled in the past twenty years, and may well be true that the importance of Russian d Japanese and possibly Spanish will continue to crease and that of French and German to decrease. does not, however, seem reasonable to anticipate, on the most chauvinistic forecast, that the contributions of each linguistic group will in the foreseeable future be proportionate to its size. Chinese may come to assume major importance; but there is little evidence as yet of any vernacular language emerging in India or Pakistan capable of overcoming the practical difficulties involved in replacing English as a *lingua franca* of scientific communication.

Such a forecast, indeed, implies a political climate most unfavourable to continued scientific advance, and happily in sharp contrast with that manifested at the recent international conference at Geneva on the peaceful uses of nuclear energy. There was little support for such pessimism in the atmosphere of that conference, and such forecasts entirely overlook two important restraining factors, one primarily psychological and the other financial. If nationalism prevails to the extent implied in Mr. Vickery's prediction, we are more likely to re-enter the dark ages than to approach one of free communication of ideas and unrestricted scientific and technical advance.

The psychological factor is indicated in the valid comment, made in replying to Dr. Keys's protest, that it is much more difficult to write a paper accurately in a foreign language than it is to translate a paper from a foreign language. That is true; but it equally follows that a paper is likely to be more accurate if the writing into a foreign language is done by the author himself or in association with the translator, than when done by some translator not in direct touch with the author. If our primary concern is for accuracy, we can scarcely escape association of the author with the task of translation.

The real factor, however, as is well realized, for example in the Scandinavian countries, is that a nation using what may be termed from a world point of view a minority language cannot escape bilingualism if it desires to attain high standards of culture and scholarship. It cannot afford to cut itself off from direct access to the world's literature or from discussion with professional men in other countries of new advances in science, in technology, in art and sociology, which limiting itself to its own language would involve. The choice of which major language to use may be difficult, and Mr. Vickery may be quite right in predicting that the Asian peoples may adopt Chinese and possibly some other indigenous language as a *lingua franca* throughout that area. But that the scientist in Java, in India, in Japan, in Nigeria or elsewhere can keep himself abreast of scientific advance in the world by relying solely on a knowledge of his own vernacular, and that he will not acquire a working knowledge of at least one major scientific language, is inconceivable. It ignores, in fact, the scientist's own desire to publish his work where it will be known and read by his scientific colleagues whatever their race.

The financial factor is likely to restrain excessive nationalism still more effectively. Even in Great Britain, major scientific societies such as the Chemical

Society with a membership of several thousand find great difficulty in meeting the mounting costs of publication. Nationalism could indeed induce Governments to bear a large proportion of the costs of publication if national prestige is involved. But in countries where the demands on Government are likely to be greatest if publication of new scientific and technical periodicals in a minority language is to be possible, economic resources are already stretched and limited, and there are likely to be strict limits to the support which the Governments can give to ventures that promise no solid return and only pander to national vanity.

Nor can the prospective publisher of such new scientific and technical periodicals count on a wide overseas demand. Few scientific and technical libraries are even now able to subscribe to all the scientific and technical periodicals they wish, or to buy the number of copies of individual periodicals that efficient service would suggest. The figures for expenditure on periodicals by the university libraries of Great Britain, which are given in the annual returns from universities and colleges issued by the University Grants Committee, show not only how limited are the funds expended for that purpose, but also how far over the past decade or more such expenditure has failed to keep pace with the mounting costs of scientific and technical periodicals. Figures given for a few of the larger technical college libraries by Mr. C. H. Wright in a paper in *The Engineer* last May show that even such major institutions as the Manchester College of Technology, the Royal Technical College, Glasgow, the Northern Polytechnic and the College of Technology and Art, Leicester, have to be severely selective in their range of periodicals.

It is unrealistic to assume that to-day a new scientific or technical periodical can count on more than a limited volume of support, unless in most exceptional circumstances. From the purely scientific or technical point of view, everything points to the desirability of counteracting the unavoidable tendency to specialization by concentrating publication in a relatively few major periodicals in languages which are widely understood and read. From that point of view it could, of course, be urged that use of some one universal language would have an overriding advantage without tending to encourage chauvinism. Apart, however, from the practical difficulties in selecting such a language, Mr. Vickery's historical survey suggests that for the present, in any event, such a proposal is unrealistic and premature, even if we discount somewhat the development of vernacular literature in Eastern Europe, Asia and Africa.

Mr. Vickery concludes from his survey that science has been faced twice before with a great language problem, and that each time the barrier to scientific communication fell to an organized attack on it by men of great zeal and scholarship, patronized and financed by the highest authorities in the land. It is not necessary to adopt that conclusion without reserve in agreeing with him that the pressing and more complex problems of scientific and technical publication in Britain can only be solved by a similarly grand plan of attack. Mr. Vickery does outline such a plan, but he makes several sound gestions as to what is needed, and these suggest call for study and support by professional bodies learned societies as much as by librarians.

The first need, Mr. Vickery suggests, is for effec bibliography—a list of all books and papers lished. Although, as he rightly remarks, this prim need is at present only imperfectly met and ther much overlapping, it should be noted that the scie centres of Unesco are attempting to deal with problem and have done something to meet the ne of the Middle East, Asia and the South Ameri countries. The second need, he suggests, is translations, or at least précis, of the more import papers. This need Mr. Vickery discusses in m detail, without, however, indicating the extent which use is made of English in this respect. rightly emphasizes, however, that attention sho be concentrated on the major scientific periodic and to do so would probably encourage the inher tendency of the scientist to publish in the m widely read and used periodicals.

On the third need, for more facilities for gett translations of any particularly useful paper, Vickery brings out the inherent difficulties as gards speed, accuracy and cost, emphasizing need for more good technical multi-lingual dicti aries and for scientists with a good knowledge of t or more languages. He indicates something of possibilities of mechanical translation but emphasi the need for further organization and co-operation this field, including the formation of scientific tra lation bureaux. He does not claim that his su gestions are novel but merely that they contin current trends.

What is needed, Mr. Vickery argues, is the co certed planned attack on the whole problem scientific communication already mentioned. T prelude to such collaboration of scientists, translato and teachers as he suggests would seem to be preliminary study of the various aspects of t problem by professional bodies and learned societi of the scientific world, as well as by librarians a information officers. A weakness of Mr. Vickery survey is, in fact, the omission of any reference what has already been done in this field by t Abstracting Board of the International Council Scientific Unions. Co-operative efforts in physi have now extended to chemistry and promise cover biology and mechanics also, while the feasibili of a comprehensive Russian to English translati service has been explored and an initial effort start by the American Institute of Physics. A lead clearly required by the scientist, however, a that lead should not only emphasize the vit importance of free communication of knowled and ideas, but also the incompatibility of scienti advance with the nationalism which in the pa forty years has done more than anything else hinder communication and obstruct scientific a vance. On that issue neither the self-respect of t scientist nor the prudent use of resources permi compromise.

# THE UNITED NATIONS FOOD AND AGRICULTURE ORGANIZATION

## e Story of FAO

y Gove Hambidge. Pp. xii+303+30 plates. (New
ork : D. Van Nostrand Company, Inc. ; London :
acmillan and Co., Ltd., 1955.) 48s. net.

OF all the activities of the United Nations, none seems likely to have more lasting effects than e Food and Agriculture Organization, often known FAO for short, and not to be confused with FOA, e Foreign Operations Administration of the United ates, which sometimes operates alongside though ways in harmony and with no overlapping. The od and Agriculture Organization was founded in uebec in October 1945 with the purpose of carrying the "War against Want" which was one of the clared purposes of the historic Atlantic Charter, d the tenth anniversary was but recently celeated on October 15 last in the Organization's birthace. The British people can justly feel proud of e leading part played in its foundation by Stanley L. Bruce, now Viscount Bruce of Melbourne ; F. L. cDougall, also of Australia ; and John Boyd Orr, ow Lord Boyd Orr. Bruce's famous speech at the eague of Nations meeting in 1935 directed attention the anomalous situation that had then arisen : griculture in the advanced countries was seriously epressed because farmers could not sell the food hey were producing, and they were advised to roduce less, while in the less-advanced countries illions of people went hungry and suffered accordgly in health and efficiency. He urged the imperative ecessity of effecting a "marriage of health and agriulture". The idea gradually developed. A few years ter (1942) McDougall proposed the establishment f a Food and Agriculture Organization of the United ations to study problems of nutrition and food upplies in the different countries and to foster reater output wherever necessary ; by 1945 the rganization was established with John Boyd Orr s head. An account of its achievements is now given y the well-known American agricultural writer, ove Hambidge, in the present book.

No fewer than seventy-one countries contribute to he Organization ; but the largest part of the cost—0 per cent—is borne by the United States, and the econd largest—10·5 per cent—by Great Britain, this eing the relative numbers of the population, though relation to the national income per head the ritish contribution is double that of the United tates. The budget for the ordinary programme of ork is 6 million dollars annually.

Its best-known work is the *Survey of the World ood Supplies*, produced periodically, which shows ow much food each country is producing and xpresses the results as calories supplied per head er day ; these are compared with the numbers onsidered desirable. These statistics are the best vailable ; unfortunately, the U.S.S.R. and its atellites do not participate, so that they have to be xcluded from the tables, and we have little trustorthy information about their food resources.

More important than the statistical records is the echnical aid offered to the countries where the food upplies are obviously inadequate. This began in a mall way at the Geneva Conference in 1947 and was reatly extended after the 1950 Technical Assistance Conference of the United Nations when fifty governments subscribed some 20 million dollars for technical aid. The United States contributed 60 per cent of this sum, 29 per cent being for the Food and Agriculture Organization and the rest going to the World Health Organization, Unesco and other bodies. The story of the resulting achievements occupies a large part of the book.

The first important operation was in China, where a campaign was started against rinderpest, estimated at that time to be killing a million animals a year there. Fortunately, a vaccine had been discovered during the Second World War, the search having been stimulated by the fear that the Germans or the Japanese might liberate the virus in North America and so wipe out the cattle population. Suitable methods of use in China were worked out. Chinese technicians were trained, and the programme included the vaccination of some fifteen million cattle. Other important agricultural improvements were also undertaken and large sums of money had already been spent when for political reasons the teams had to leave China late in 1948. Similarly, much good work was started in Poland and Czechoslovakia ; but these countries also withdrew from membership, leaving the work uncompleted.

Elsewhere, however, very valuable results have accrued : animal diseases have been better controlled, and higher output of food crops achieved. Tests have been made in a number of countries of hybrid maize, one of the United States' great gifts to the world : it is proving very valuable in the Central and Eastern Mediterranean countries, giving up to 50 per cent higher yield than the older sorts, and it now forms some 30 per cent of the Italian crop. In Siam, fish culture in ponds is being extended to make good some of the shortage of protein in the people's diet ; in the Arabian peninsula joint action against locusts has been organized ; much work is being done on rice ; and R. O. Whyte and his team have promoted surveys of the grasslands of India and other countries.

No less than fifty-three countries are being helped by the Food and Agriculture Organization, and some three hundred experts are engaged in the field. Steps are taken to train local people to continue the work after the Organization's teams leave. It is a great enterprise never before attempted in the history of the world, and the sincerest wishes for its success must go out to the director-general, P. V. Cardon ; the director of the very important Agricultural Division, F. T. Wahlen ; and all the staff.

E. John Russell

# SURVEY OF CANCER

## One in Six

An Outline of the Cancer Problem. By Dr. I. Hieger. Pp. 80+15 plates. (London : Allan Wingate (Publishers), Ltd., 1955.) 12s. 6d. net.

IT is almost as difficult to review a popular book on cancer as to write one, and for similar reasons. The subject ranges over such a vast canvas that one is always acutely aware of numerous important omissions and of the minor distortions which inevitably appear. No one can assimilate all the facts, and a selection tends to be confusing without the aid of an accepted unifying concept of the nature of cancer. In writing a short popular account, one is compelled to stress those aspects most dominant in one's own experience, and Dr. I. Hieger naturally stresses the important role of the chemical carcinogens in etiology. He was in the team which first isolated from coal tar a pure chemical carcinogen, and he gives us the most interesting story of this pioneer discovery. Moreover, we have seen lately the firm linkage of exposure to tobacco and industrial smoke to the tremendously rising incidence of lung cancer. Up to now, the types of human cancer with a definitely proved relation to exposure to chemical carcinogens, though important, were a small part of the human total. If it is shown that lung cancer is in fact due to exposure to chemical carcinogens in smoke, their practical significance in human cancer will become of greatly enhanced importance.

It is possible that these statistical findings have stimulated the author to write this book and to devote one out of the five chapters to lung cancer. Even here, however, while the firm evidence for its relationship to cigarette-smoking is clearly presented, the assumption that this is due to the carcinogens undoubtedly present in the smoke, even if in very small concentration, cannot yet be justified. Of course, even if this assumption is not true, it will not affect in the slightest the practical danger of heavy cigarette-smoking. But knowledge of the real mechanism could very well affect profoundly our mode of approach to the millions of cigarette smokers, a substantial proportion of whom may, on the basis of a simple carcinogen hypothesis, be doomed to die of cancer of the lung. This illustrates one of the difficulties inherent in the popular approach to an enormously complicated subject which also has profound applications to the welfare of man—so profound indeed that the average man manages to forget about it completely and, short of man-handling, cannot be induced to listen to a popular lecture on the subject.

It is difficult to know how far any popular book on cancer can give anything but a confused idea of the present trends in research. It can, of course, state what some of them are and indicate some of the major advances of the past. Long experience of teaching medical students reveals that the great majority of them retain only the haziest notion of even the most elementary facts about cancer research, despite having received systematic instruction. This suggests only a faint possibility that the ordinary layman will derive any clear picture from popular accounts at the present time. On the other hand, the scientist would find much of the present book too elementary in his own field, and would get an incomplete idea of the scientific basis of the problem in other fields. This is not a criticism of this book in particular, which is a fairly good specimen of its kind. It is quickly read and gives quite a lot of interesting statistical information about cancer mortality-rates. Here, incidentally, the author brings out the point that the overall cancer death-rate, adjusted for age grouping, has not significantly altered during the past forty-five years. He does not comment on the disturbing fact that while diagnostic methods have continually improved and treatment facilities widely expanded, the mortality from cancer remains practically the same. The cancer problem is full of such paradoxical facts; and since all are subjects of debate and argument, it would be unfair to expect any writer to enter into these controversial issues in a popular account. The reader who would like to know something about a few of the many thousands of facts which cancer research has elucidated should turn to Dr. Hieger's book, for it is some ti since we had a popular book from an establisl scientist in the field. The book, therefore, has merit of being reasonably up to date.

# THE TEACHING OF MODERN PHYSICS

**Introduction to Experimental Physics**

By Prof. William B. Fretter. (Prentice-Hall Phys Series.) Pp. viii+349. (London and Glasgo Blackie and Son, Ltd., 1955.) 35s. net.

THIS book consists of notes, taken at the ti and written up by Dr. W. B. Fretter, of lectu given by fifty-two lecturers in the University California, Berkeley. The chapters deal with a wi variety of subjects, from low-temperature work a spectroscopy to pile techniques and cosmic rays, within 344 pages. It is not surprising, therefore, th the information provided is exceedingly scrapp There is no consistent thread running through t book, and sometimes scarcely one going through single chapter.

Unfortunately also, the separate scraps are ther selves often incoherent. For example, ten pages a allotted to the subject of cyclotrons, including account of the principles of the ordinary cyclotr and the synchro-cyclotron. There is no picture what a cyclotron looks like, and no intelligib description of the ion source or of the radio-frequen system. Also, although phase stability is briefly d cussed, there is no general description of partic oscillations. Instead, the chapter looks like a set notes by a student who, already knowing a good de of the subject, jots down the points that intere him. These include very brief remarks of vario engineering items, mostly associated with the Berkel 184-in. cyclotron. This kind of treatment is qui typical, and in fact some other topics are even mo sketchily dealt with.

Although a student already well versed in t various subjects will certainly find many co siderations and ideas which he may not ha thought about, for a raw student the book would useless.

This is not the way to teach physics. A book or set of lectures should have as its main aim coheren This can be done at any level, elementary or advance If the book is to be advanced, since it should inclu a complete account of the subject, it will need to of appropriate length. It is not possible to tre thirty-two separate, mostly independent, topics at rather advanced level with on the average only eleve pages for each. If one takes at random any of th topics dealt with, say magnet design, this shou either be dealt with from an elementary point view in a book about electromagnetism, or, if on wants to go into detailed practical applications, special book would be required. A few pages miscellaneous information serve no purpose.

In any event, I think it is a mistake to try t teach elementary techniques in isolation. It is muc better to give a treatment dealing with all the aspec of the subject. For example, cyclotrons are be treated in connexion with the subject of nucle disintegrations. This is the usual method, and I a sure it is right.

H. W. B. Skinner

# NEW MONOGRAPH ON DDT

T

s Insektizid Dichlordiphenyltrichloräthan und
ne Bedeutung. Herausgegeben von Paul Müller.
d. 1. (Lehrbücher und Monographien aus dem
biete der Exakten Wissenschaften. Chemische
ihe—Band 9.) Pp. 300. (Basel und Stuttgart:
khäuser Verlag, 1955.) 37.50 Swiss francs;
.50 D. marks.

HE insecticide DDT has been well known for a dozen years, though latterly a number of new nthetic compounds have emerged to challenge its periority in various fields. However, there are t so many new types of insecticide as may appear m the lists of names; most of the newcomers long either to the chlorinated terpene group (to ich γ-benzene hexachloride is toxicologically ied) or to the phosphoric acid series. The dis-very of a new class of insecticides is, in fact, rare. DT marked such an advance that it is generally nsidered to have opened a new era of pest control, d it continues to be widely and satisfactorily used r many purposes.

A few years ago Dr. P. Müller, of Geigy, who was rgely concerned with its discovery, decided that e time was ripe for a new monograph on DDT. he first volume has now appeared, in the form of symposium of five sections, by Swiss, British, ustrian and Swedish authors. Four of the contri-utions are in German and one in English, with ummaries in the alternative language. One or two ooks on DDT have already been published, though one recently. About the best was that by T. F. est and G. A. Campbell (1950); but these authors dmitted delays in publication, and their text contains o reference later than 1946. (To remedy the efect, they added a supplement of more than eight undred references for 1947 and 1948, which gives me idea of the enormous output of papers on the ubject.)

The present monograph takes the account up to 953; but the more recent work has added very ttle to the data on physical and chemical matters hat comprise Section 1, by Dr. Müller himself. ection 2, by Prof. V. B. Wigglesworth, summarizes ur knowledge on the mode of action of DDT, this ontribution being by far the most generally inter-sting. It begins by considering factors involved in he contamination of insects by DDT and continues o the final minutes of intoxication—so far as they re known. This lucid survey integrates the findings f 137 papers, 80 per cent of them published between 946 and 1951. After reading it, we still do not now how DDT kills; but the possibilities are greatly arrowed.

The remaining contributions are of a more practical ature and deal with the use of DDT against parti-ular types of pests. Section 3, by Dr. E. Bernfus, f Vienna, deals with the control of stored product ests, especially those of breweries. In view of the erious importance of toxic residues, methods are escribed for determination of DDT traces in food. ection 4, by Dr. O. Walchli, of St. Gallen, ustria, discusses the use of DDT for protecting oollen textiles against clothes moths and carpet eetles. The final section, on control of forest insect ests, is by Dr. V. Butovitsch, of Stockholm. It ives full details of spraying and dusting by aircraft nd from the ground against the woodland pests. No information on control of agricultural and horticultural pests is given in this volume, nor are insect disease vectors or parasites mentioned; no doubt they will receive attention in the next volume.

# GEOPHYSICAL RESEARCH IN NORTH AMERICA

Advances in Geophysics
Edited by H. E. Landsberg. Vol. 2. Pp. x+286. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 7.50 dollars.

THIS volume is the second in a series. It contains five essay reviews, each approximately fifty pages in length, dealing with recent advances in various branches of geophysics. Each is by a separate author or authors; but the whole volume is edited by H. E. Landsberg, of the United States Weather Bureau, assisted by a small advisory committee. As might be expected of a composite work of this kind, the style and quality of the different contributions vary considerably; but, on the whole, a high standard is maintained. Each essay contains a good bibliography, and author and subject indexes are provided.

In the first essay, on advances in radar weather, J. S. Marshall, W. Hitschfeld and K. L. S. Gunn (McGill University) describe typical precipitation patterns and give an outline of the ways in which quantitative data can be derived from radar signals. In "Methods of Objective Weather Forecasting", by I. I. Gringorten (Air Force Cambridge Research Center, Cambridge, Mass.), various objective methods of weather forecasting are classified, and the success and future objective of such systems discussed. W. J. Pierson, jun. (Department of Meteorology and Oceanography, New York University), discusses wind-generated gravity waves, and gives an outline of mathematical methods of describing such waves. This can be applied to analyse the form and motion of actual waves at sea. Some practical methods of observing and forecasting are also considered. In the essay on geological chronometry by radioactive methods, J. L. Kulp (Lamont Geological Observatory, Columbia University, New York) gives brief accounts of the lead, carbon-14, strontium, potassium, helium and ionium methods of radioactive dating and also reviews some other potential methods. The final essay is on earthquake seismographs and associated instruments, by H. Benioff (Department of Seismology, California Institute of Technology). The progress in design during the past twenty-five years is illustrated by short descriptions of some thirty different types of seismograph; advances in methods of recording and time-keeping are also summarized.

The whole volume is written and produced in North America. It is not surprising, therefore, to find that most of the work described has been carried out either in the United States or Canada. Within this field, the reviews are fairly complete; but they could be improved if research carried out in other countries were more fully treated. As a series of reviews of recent geophysical work in North America, this book can be strongly recommended, and future volumes in the series will be awaited with interest.

## SOME RECENT EXPERIMENTS IN FRICTION*

### Friction of Solids at High Speeds

MOST of our earlier experiments on friction have been conducted at low or moderate speeds of sliding which come within the range that an engineer might normally use. These speeds rarely exceed 30 m./sec. (70 m.p.h.). It has been shown[1] that, even at low speeds, a localized heating can occur and cause a softening or melting at the summits of the surface irregularities. On prolonged sliding this causes surface flow and polishing, but the heating is concentrated mainly in the very small regions of intimate contact. At low speeds the friction of metals is due primarily to adhesion and shearing of the contact regions, and the surface damage is characteristic of this. More recently, we have been studying the behaviour of surfaces sliding at very high speeds—up to 1,000 m./sec. (2,200 m.p.h.). An engineer would certainly regard such speeds as excessive ; but they are reached, for example, by the copper driving-band of a shell when it is leaving the muzzle of a gun.

In the laboratory these speeds can be achieved by using a technique which has been developed by Beams[2] for his ultracentrifuge. A steel sphere is suspended by an electromagnet, its top is illuminated and the shadow falls on a photoelectric cell. If the ball sinks, the current in the magnet will increase ; if it rises, it will decrease so that the ball is held in a stable vertical position. It can be caused to spin by a rotating magnetic field. If the ball is surrounded by an evacuated glass chamber, the forces opposing its rotation will be very small and it will soon reach a very high speed (more than a million revolutions a minute for a steel ball of ¼ in. diameter). The speed is limited only by the rupture strength of the ball. As the top of the ball is illuminated, an etch mark can be detected by means of a photomultiplier cell and transmitted to a cathode-ray oscillograph or an electronic frequency meter and recorder. The sliding speed can thus be measured accurately.

In our friction experiments the fast-spinning ball rubs against three symmetrically arranged vertical surfaces as shown schematically in Fig. 1. All three are initially in such a position that they cannot interfere with the ball during its acceleration. Two of them are mounted rigidly, and when the desired speed is reached, a spring is released which pushes the third surface against the ball and thus moves it a very short distance sideways until it also touches the other two stationary surfaces. A measurement of the deceleration under the known load gives the coefficient of friction.

If the spring-operated surface is withdrawn, the ball returns quickly to its free-spinning position and can be slowed down in such a way that the high-speed wear marks are not further damaged. In th way it is possible to measure the friction and t study the physical processes occurring over a gree range of speeds, up to 1,000 m./sec. The result plotted in Fig. 2 were obtained with a steel bal bearing of ¼ in. diameter rubbing against surfaces ( copper (curve *A*) and of bismuth (curve *B*). Th load was 20 gm. The friction was measured immedi ately after the sphere had touched the surface Both metals show a very great decrease in th coefficient of friction as the speed is increased. Th low values measured at high speeds are striking, sinc the surfaces are clean and in a moderate vacuum

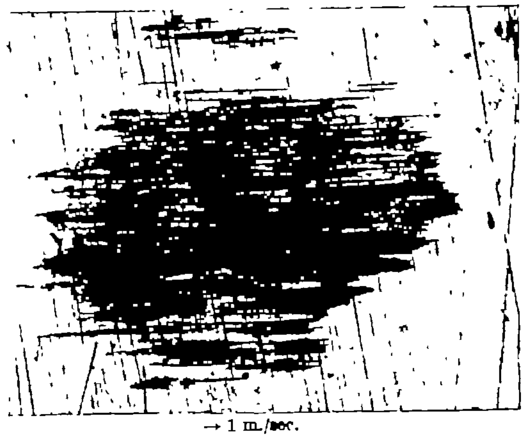
* From a Friday Evening Discourse given at the Royal Institution, London, on May 6.



ig. 3(a). Slow-speed sliding wear on copper, showing normal abrasion (× 160)

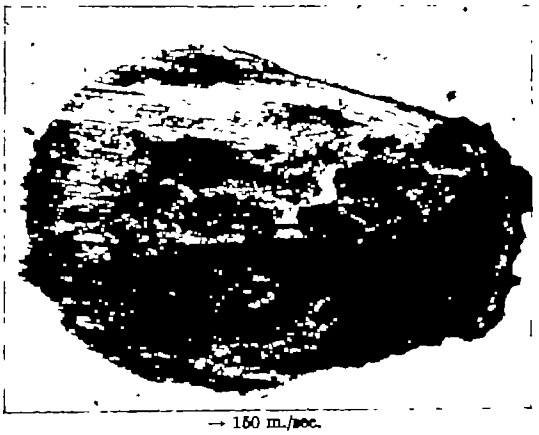


Fig. 3(b). Medium-speed sliding wear on copper, showing flow of metal (× 160)

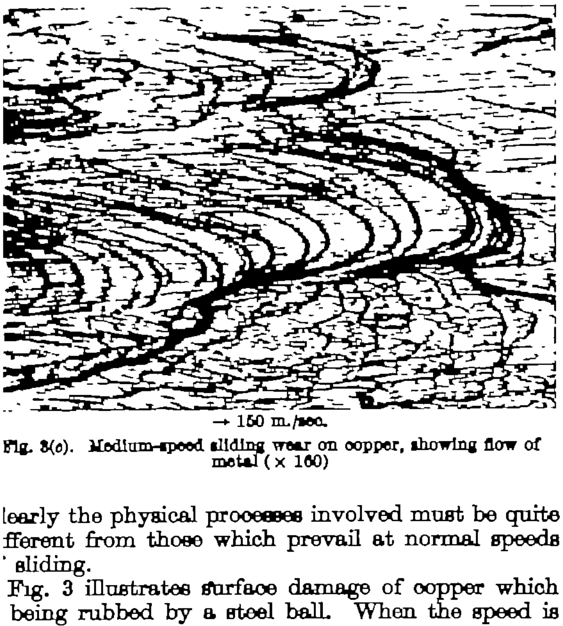

Fig. 3(c). Medium-speed sliding wear on copper, showing flow of metal (× 160)

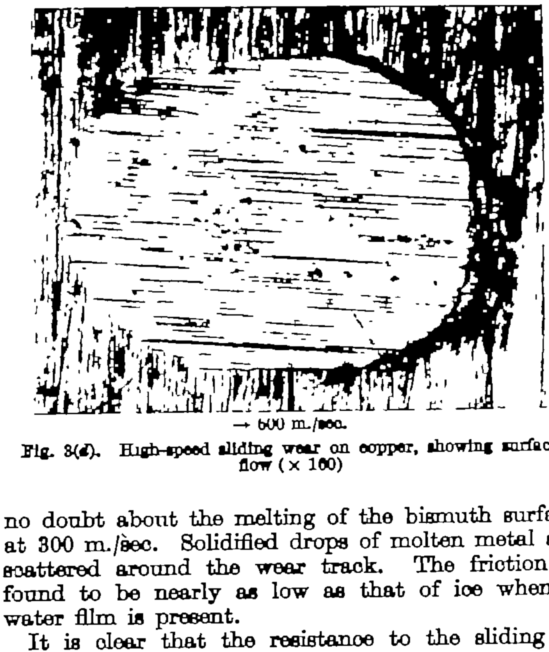

Fig. 3(d). High-speed sliding wear on copper, showing surface flow (× 160)

learly the physical processes involved must be quite fferent from those which prevail at normal speeds sliding.

Fig. 3 illustrates surface damage of copper which being rubbed by a steel ball. When the speed is ıly a few metres per second (Fig. 3a) the copper ırface shows the characteristic marks of abrasion. ne would expect a high friction, and in a vacuum, ıce the oxide films are removed, seizure occurs. At 50 m./sec. (Fig. 3b) the surface damage is clearly of new type. The copper is flowing, and a considerable nount of it (up to 0·5 mgm.) is picked up by the eel ball. The coefficient of friction is reduced to out 1·5, but a deceleration from this speed would pidly lead to seizure. The flow of copper after ore prolonged rubbing under the same conditions 50 m./sec.) is illustrated in Fig. 3c. If the sliding faster (Fig. 3d), the surface layers of copper pproach the molten state and may act as a lubricant the same way as water on ice (see below). The iscosity of molten copper is of the same order of agnitude as that of water. The coefficient of friction 600 m./sec. falls to the very low value of 0·2. As on as the rubbing surfaces are separated, the copper lidifies to form a relatively smooth shiny surface. he wear per unit distance slid is very much less an that observed at normal speeds.

With bismuth, which is a bad thermal conductor nd has a low melting point, the surface melting and w friction should occur more readily. Fig. 4 leaves no doubt about the melting of the bismuth surface at 300 m./sec. Solidified drops of molten metal are scattered around the wear track. The friction is found to be nearly as low as that of ice when a water film is present.

It is clear that the resistance to the sliding of metallic surfaces is not constant but can fall to very low values at high speeds. At these speeds the wear

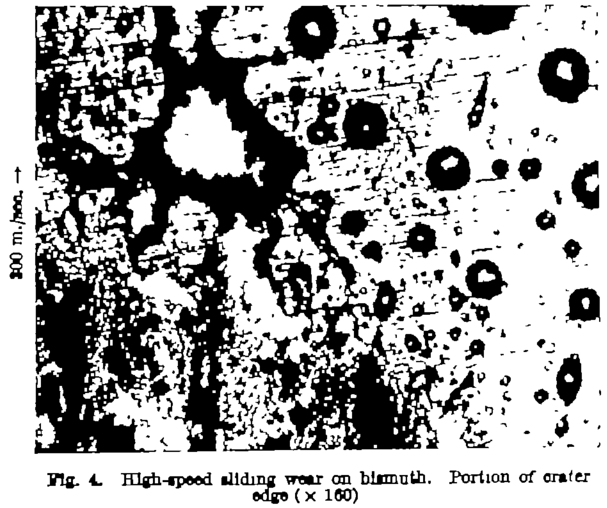

Fig. 4. High-speed sliding wear on bismuth. Portion of crater edge (× 160)

per unit distance of sliding is also very much less than that observed at normal speeds. There is evidence, both from the frictional behaviour and from the examination of the surface, that this behaviour is due to the formation of a thin layer of molten metal which acts as an effective lubricant film.

## Friction on Snow and Ice and the Development of some Fast-Running Skis

We may draw an analogy between the mechanism of the friction of metals at very high speeds and that of skiing. Ice is an interesting solid from the frictional point of view because its friction can be lower by an order of magnitude than that of other crystalline solids. Osborne Reynolds[3] suggested that the low friction in skating was due to a water film formed by pressure melting. Some years ago an experimental study[4] of the friction of snow and ice was made at the Jungfraujoch Research Station. The friction of cold snow or ice is very high; it is only near 0° C. that the friction is low. The experiments supported the view that the low friction is due to surface melting. They showed, however, that pressure melting is a factor only at temperatures very close to 0° C. and with slow-moving surfaces. If the sliding speed is appreciable and the temperatures are below 0° C., the local surface melting is produced, not by pressure melting but by the frictional heating of the sliding surfaces. Under the conditions which exist in skiing and sledging, it is this frictional heating and melting which is the major factor responsible for the low friction. Experiments with sliders of different thermal conductance were in harmony with this view. These early experiments were carried out with miniature sliders.

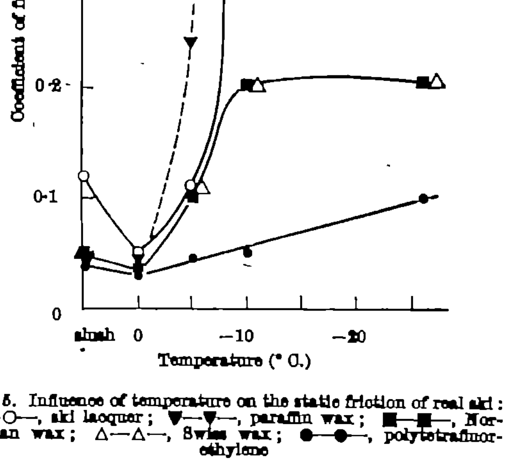

Fig. 5. Influence of temperature on the static friction of real ski: ○—○—, ski lacquer; ▼—▼—, paraffin wax; ■—■—, Norwegian wax; △—△—, Swiss wax; ●—●—, polytetrafluorethylene

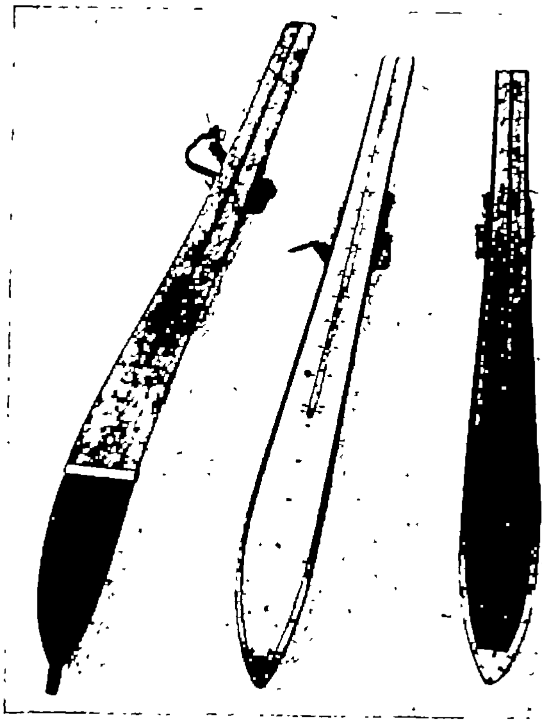

Fig. 6

Recently[5], the experiments have been extended real skis, and a study has been made of the behavio of some new plastic materials sliding on ice and sno The experiments support the earlier conclusions tha the low friction on snow and ice is due to a surfa melting produced by the friction-heating of the slidin skis. The rubbing of the ski at the localized point of contact of the snow crystals causes a surfa melting. Very cold snow or ice behaves like an other crystalline solid. At low temperatures th static friction (or the slow-speed friction) of ice high, and it is not until the ski begins to slide at a appreciable speed that the friction falls to a sma value. This is illustrated by Table 1.

Table 1. Influence of Speed on Friction. on Ice at − 10°

| Ski surface | Coefficient of friction: Static | At 3 cm./sec. | At 5 m./sec. |
|---|---|---|---|
| Waxed wood | 0·20 | 0·18 | c. 0·02 |
| Lacquered wood | 0·40 | 0·36 | c. 0·03 |
| 'Perspex' | 0·35 | 0·32 | c. 0·03 |
| Aluminium | 0·38 | 0·34 | c. 0·04 |

The influence of temperature on the static frictio of skis on snow is illustrated in Fig. 5: most of thes surfaces (except polytetrafluorethylene) are standar ones used in skiing. Two important points whic may be noticed from this figure are, first, that th friction for all these surfaces falls as the snow warm up and is at a minimum at 0° centigrade; and second, the very low friction given by the plasti material polytetrafluorethylene under all conditions An account of the general frictional behaviour o this material has been given elsewhere[6]. Method used for attaching the plastic to the skis are show in Fig. 6. The behaviour of polytetrafluorethylen on snow is due partly to its inherently good frictional properties and partly to the fact that it is not wetted by water. There is evidence that the frictional behaviour of different solids sliding on snow i ble 2. Timed Descents: Comparison of Waxed Ski with New Ski of Polytetrafluorethylene

Crystalline spring snow; air temperature 5° C.; snow temperature 0° C.; gentle slope of length 700 ft. (tracked)

| Weight on ski (lb.) | Time of descent (sec.): Conventional ski with Norwegian wax and paraffin | New ski of polytetrafluorethylene |
|---|---|---|
| 168 | 61 | 42 |
| 140 | 83 | 54 |

New snow fallen a few hours previously; air temperature 10° C.; snow temperature 0° C.; unloaded ski (tracked)

| Details of slope | Time of descent (sec.): Conventional ski, with ski lacquer | New ski of polytetrafluorethylene |
|---|---|---|
| Gentle, 20 m. long | 10 | 6 |
| Steeper, 30 m. long | 6 | 3 |

fluenced by the contact angle which the water film akes with the surface. With polytetrafluorethylene is contact angle is very high (126°), and it remains igh even after prolonged sliding on snow. This is ppreciably higher than the contact angle observed on axed surfaces which have been rubbed on snow. The xperiments suggested that polytetrafluorethylene might have interesting possibilities as a skiing surface, and several pairs of skis have been coated with it and tried out in the Alps under a variety of snow conditions during the past three years. Some timed straight-run descents under controlled conditions have also been made. The results are quite striking, some typical experiments being illustrated in Table 2.

It is clear that skis of polytetrafluorethylene are considerably faster under these conditions. They are easy to ski on, because they give a low uniform friction even when running on patchy snow. They should have useful applications not only to skiing but also to sledging and to aircraft landing, particularly on very cold, very wet or difficult snow and ice.

# SOLAR ECLIPSES AND THE IONOSPHERE

ONOSPHERIC measurements at the time of solar eclipses may be expected to yield useful informa- ion on problems such as the nature of the ionizing adiation and its distribution on and outside the isible solar disk, on theories of the formation of the nosphere and of recombination processes within the arious layers. It has long been established that the rimary ionizing source of the *E* and *F*1 layers of the onosphere is solar ultra-violet light. This conclusion s amply confirmed by both long-term measurements nd by results obtained during solar eclipses. How- ver, in the case of region *F*2 the source is less clearly lefined; eclipse effects in this region are often com- lex and the interpretation of the observations mbiguous. Certain aspects of eclipse phenomena in ll the ionospheric regions were discussed at a ymposium on "Solar Eclipses and the Ionosphere" eld in the rooms of the Royal Society, London, luring August 22–24. The symposium was organized y the Mixed Commission on the Ionosphere and ponsored by the International Council of Scientific Jnions. Some twenty-five British and fifty-five verseas delegates participated.

Opening the symposium, Mr. J. A. Ratcliffe presented a general survey of ionospheric eclipse phenmena and discussed the eclipse effects to be expected n a simple Chapman-type layer. Eclipse results for egion *E* have been reconciled with the predictions f simple theory by supposing that the process of lectron loss is recombination-like with an effective oefficient $\alpha' \simeq 10^{-8}$ cm.$^3$ sec.$^{-1}$. In most cases it has lso been necessary to suppose that the intensity of he ionizing radiation is not uniform over the solar isk, and furthermore that a measurable fraction riginates outside the visible disk. In the case of egion *F*1, eclipse estimates of $\alpha'$ lie between 5 and × $10^{-9}$ cm.$^3$ sec.$^{-1}$, and for this region there is again vidence for enhanced radiation from the same areas hich contribute to the *E*-layer ionization. In the *F*2 layer complex eclipse effects are often observed, and here it is clear that consideration must be given to the influence of movements in the layer during the eclipse. An interesting phenomenon which has received attention during recent eclipses is the temporary appearance of a new critical frequency between the *F*1 and *F*2 critical frequencies. It has been suggested that this might correspond to a separate layer, the so-called *F*1½ layer, due to some special process of electron production. However, it can be shown that if the electron loss coefficient decreases upwards, then the appearance, during an eclipse, of a point of inflexion on the *h'f* curve between the *F*1 and *F*2 layer critical frequencies is to be expected.

Mr. C. M. Minnis discussed eclipse results for region *F*2 obtained at Khartoum, Singapore, Slough and Inverness during eclipses of 1952, 1954 and 1955 and stressed the desirability of always computing the electron density/true height profile, since deductions based only on critical frequency variations can be misleading.

Prof. S. Chapman outlined the development of ideas concerning a possible corpuscular eclipse effect in the ionosphere. The observed delay of about one day between certain solar disturbances and terrestrial magnetic storms indicates that the solar particles have an average speed of about 1,000 miles/sec., and for this speed the corpuscular eclipse might be expected to occur about two hours before the optical eclipse. This difference in time would, of course, result in a considerable difference in position on the earth between the optical and corpuscular eclipses. As far back as 1919 Chapman and Milne pointed out that a speed of 1,000 miles/sec. seemed quite inadequate for particles to reach the 100-km. level, and it is now believed that if there are any corpuscular eclipse effects these may be expected to be weak and to affect only a high layer in the ionosphere. Prof. Chapman also outlined the theory of the effect of an eclipse on the Earth's magnetic field. The reduction in the electron and ion content of the ionosphere during a solar eclipse reduces the conductivity; this modifies the electric current intensity and hence affects the transient variations in the earth's field. In general, the magnetic effect of an eclipse may be expected to be quite small—the precise magnitude and nature will depend on the location of the observing site with respect to the electric current systems in the ionosphere. At stations near the foci of these systems the eclipse effect may be expected in the vertical force, whereas in equatorial latitudes it should appear in the north horizontal force.

Recent successful measurements of geomagnetic effects during a solar eclipse were described by Mr. J. Egedal. Records of magnetic declination from fourteen observatories in Europe showed small but quite definite effects during the eclipse of June 30, 1954. The magnitude was of the order to be expected if the ionospheric currents concerned flowed near the level of region *E*. Dr. T. Nagata presented similar results for observations in Japan during the eclipse of May 9, 1948. In this case it was found that the magnitude of the changes in the east component were consistent with calculations based on the observed eclipse decrease in electron density in the *E*-layer.

One session was devoted to a discussion of present solar knowledge with particular reference to ionospheric studies. Prof. C. W. Allen showed that long-period ionospheric data for regions *E* and *F* require a quiet component from the whole Sun together with a component associated with centres of activity. Dr. M. A. Ellison discussed some ionospheric effects of solar flares, and Prof. D. R. Bates presented a short summary of present views concerning the theory of layer formation. The *D* layer is now believed to be due to photoionization of nitric oxide by Lyα, the *E* layer to X-rays centred mainly near 40 A., and the *F*1 and *F*2 layers partly to longer X-rays and partly to ultra-violet ionization of atomic oxygen. Mr. M. Ryle and Dr. J. P. Hagen respectively presented summaries of knowledge concerning the solar corona and chromosphere as deduced from solar radio noise studies.

A session on recombination in the ionosphere was introduced by Prof. D. R. Bates, who emphasized that recombination takes place through a complex variety of processes. For the higher layers the basic mechanism is probably dissociative recombination. In the case of the *D*-layer the position is still open. To explain the very large recombination coefficients for the *D*-layer, the mechanism might be negative ion recombination, it might be ordinary dissociative recombination or the process might involve complex ions. Prof. J. Sayers briefly outlined laboratory experiments on recombination processes now in progress in the University of Birmingham.

Measurements of effective recombination coefficients deduced from solar eclipse ionospheric observations were presented by Mr. C. M. Minnis, Dr. O. Burkard and Dr. K. Rawer. Mr. Minnis showed how the effective recombination coefficients deduced from eclipse measurements depend critically on assumptions concerning the amount of residual radiation at totality. He also showed that although it is often difficult to give accurate estimates of $\alpha'_E$ and $\alpha'_{F1}$, it is possible, both from measurements of the normal diurnal variations in $fE$ and $fF1$ and from eclipse observations, to obtain reliable estimates of the ratio $\alpha'_E/\alpha'_{F1}$. Dr. Rawer stressed the errors likely to be involved in evaluating effective recombination o efficients by applying an over-simplified theory eclipse observations. The usual assumptions monochromatic ionizing radiation, of an isotherm atmosphere and of simple recombination process are not satisfied, and in presenting future ionospher results he suggested that data should be given f parameters which are independent of any speci theories. Dr. Burkard considered ionospheric da for the eclipse of February 25, 1952, and showed th if the results are interpreted not in terms of the usu simple theoretical equilibrium equation but in term of a modified equation in which layer conditions a not assumed to be isothermal, then there is r necessity to assume a non-uniform distribution of t sources on the solar disk as had been done by oth workers.

Mr. W. R. Piggott discussed eclipse observatio of vertical-incidence ionospheric absorption at Ibada in 1952 and showed that eclipse changes in th absorbing region and in regions *E* and *F*1 a appeared to indicate similar (irregular) distributio of the emission of the ionizing radiation from th Sun. Interesting eclipse observations on the lowe ionosphere were described in papers by Dr. B Weekes and by Dr. E. A. Lauter.

In the final session of the meeting, Dr. S. I Gossner directed attention to some unusual ge metrical conditions pertaining to the solar eclipse c October 23, 1957. These conditions result from th fact that the axis of umbra will pass near the surface c the Earth without actually touching it and the centr lines will intersect the ionosphere twice. For vertica soundings this second intersection will take place i the general area of the Falkland Islands Dependencie

The principal points which would appear to hav arisen from discussions at this symposium are th following. In the case of region-*E*, some 10–15 pe cent of the ionizing radiation comes from beyon the visible solar disk. The uncertainty concernin the actual magnitude of this residual radiation mean that there is corresponding uncertainty about th effective recombination coefficients deduced fro eclipse observations. In interpreting eclipse result it is also very important to consider what is th appropriate value for the index *m* in the expressio $fE \propto (\cos\chi)^m$ ($\chi$ = solar zenith angle). In general experimental results do not fit the value predicted b simple theory, namely $m = 0{\cdot}25$, and during th discussions a number of possible causes for th observed variations in *m* were brought to light. I the case of region *F*1, the above difficulties are agai all present. It is clear that, in eclipse observation on this region, changes in the electron density/tru height profile and not merely changes in the critica frequency $fF1$ must be considered. In the case o region *F*2, similar profiles must also be calculated and the discussions also clearly brought out th importance of movements in this region. Severa speakers referred to the appearance of the $F1\frac{1}{2}$ trac during eclipse observations, and although som results suggested that this phenomenon is confine to places of low magnetic dip and to eclipses of larg magnitude, it was not clear that this is always th case.

During the symposium, limitations of time onl permitted the presentation of summaries of a few o the fifty papers submitted. These papers, togethe with the discussions, will shortly be published in a single volume by the International Union for Scientifi Radio.

W. J. G. BEYNON

# GEORGIUS AGRICOLA (1494–1555)

By JOAN M. EYLES

IF one were to ask a well-informed student of the history of science to name the three most important scientific books published in the first half of the sixteenth century, his first choice would certainly be the "De Revolutionibus Orbium Coelestium" by Copernicus, published in 1543. Next he would probably select the "De Humanis Corporibus Fabrica" by Vesalius, which also appeared in 1543. He would probably hesitate before making a third choice, and might possibly decide in favour of one of the great herbals, perhaps that of Leonard Fuchs, published in 1542. If reminded of Agricola, he might answer that this author's famous "De Re Metallica" was not published until 1556, and was, in any event, like the "Pirotechnia" of Biringuccio (1540), essentially a work on technology rather than science. It is unlikely that he would be acquainted with the contents of Agricola's earlier book, "De Ortu et Causis Subterraneorum", published in 1546, which consists of several treatises, the first of which gives the book its name. Yet it can be justly claimed that this book, which contains almost all that Agricola wrote on mineralogy and geology, laid the foundations on which these sciences were built, and entitles Agricola to be ranked equally with Copernicus and Vesalius as one of the really great sixteenth-century scientists.

In many well-known histories of science, the name of Agricola either does not appear at all, or is mentioned only in connexion with his great work on mining and metallurgy, "De Re Metallica". Wolf's "History of Science, Technology and Philosophy" is an exception, for its author does record some of the geological opinions of Agricola contained in the "De Ortu". These have been extracted from the excellent notes given by H. C. and L. H. Hoover in their well-known translation of the "De Re Metallica"[1]. However, Wolf, while realizing the importance of the views which he quotes, makes no attempt to appraise Agricola's standing among the scientists of the early sixteenth century.

Lack of appreciation of Agricola's "De Ortu" is not surprising, for in most general histories of science the evolution of geology, the one subject that forms a bridge between the biological and physico-chemical sciences, is allotted a very minor role. It must be admitted that this is largely the fault of geologists themselves, who by neglecting a rewarding field of research, have failed to arouse general interest in the subject.

The neglect of Agricola by modern geologists, particularly those of the English-speaking world (for his own countrymen have always been more appreciative of his merits), was recognized by the Hoovers when they wrote in 1912: "The wider interest of the members of the medical profession in the development of their science than that of geologists in theirs has led to the aggrandizement of Paracelsus, a contemporary of Agricola, as the first in deductive science. Yet no comparative study of the unparalleled egotistical ravings of this half-genius, half-alchemist, with the modest sober logic and real research and observation of Agricola, can leave a moment's doubt as to the incomparably greater position which should be attributed to the latter as the pioneer in building the foundation of science by deduction from observed phenomena. Science is the base upon which is reared the civilization of to-day, and while we give daily credit to all who toil in the superstructure, let none forget those men who laid its first foundation stones. One of the greatest of these was Georgius Agricola".

Agricola's life has been related in some detail by Hofmann[2], and more recently by Hartmann[3]. His surname was, in the vernacular, Bauer, but he had adopted the Latin version by the time his first book, a small Latin grammar, was published in 1520, and he retained this form thereafter. He was born in Glauchau, in the Saxon Erzgebirge, at a time when the leaven of the Italian Renaissance was already working in the universities of northern Germany. Therefore, when he went to the University of Leipzig in 1514, he was able to study Greek as well as Latin, first under the instruction of an Englishman, Richard Croke, who later became lecturer in Greek at Cambridge, and then under Petrus Mosellanus, father of humanism in Saxony. Agricola spent four years at Leipzig and after graduating was appointed vice-principal of the town school at Zwickau, a place of some importance near his home. The town council of Zwickau clearly appreciated the brilliance of the young teacher, for in 1519 they opened a new tri-lingual school, in which Greek, Latin and Hebrew were taught, with Agricola as rector. Three years later, however, he returned to Leipzig as lecturer, assisting Mosellanus; and about this time he began to interest himself in the study of medicine and philosophy. A desire to hear the most famous doctors and to read the texts of Galen in the original Greek took him next to Italy. Here he spent two years, mostly in Venice, where he was closely associated with the Aldine Press, and assisted in editing the great collected edition of Galen's works in Greek, which it issued in 1525.

On returning to Zwickau in 1526 he was, so he wrote later, burning with a desire to know more of the mines and minerals so abundant in the Erzgebirge. This region had for the previous fifty or sixty years been the scene of intense mining activity. Agricola had graduated in Italy as a doctor of medicine, and in 1527 he accepted the post of *Stadtarzt* (town physician) in Joachimsthal, a new mining town in Bohemia, on the south side of the Erzgebirge. There he was in a most favourable position for following up his new interests. The mines at Joachimsthal, at that time producing much silver, supplied, some 450 years later, the pitchblende used by the Curies in their researches on radioactivity. They were first opened up in 1516, and by the time Agricola arrived the population of the district was already some 10,000, nearly all miners and officials.

The first fruit of Agricola's interest in the mines was a small volume entitled "Bermannus sive de re metallica", published at Basle in 1530 by the Froben Press, which also published most of his later works. There is a foreword, praising the book, by the great humanist, Erasmus of Rotterdam. The text takes the form of a conversation between three learned men, one skilled in mining matters; and it contains descriptions of many minerals and ores. Its publication added to the reputation of Agricola, already renowned as a classical scholar, and his friends eagerly awaited further works on the subject from his pen.

In 1530 he gave up his post at Joachimsthal, and a few years later returned to Saxony, settling at Chemnitz, another mining centre, where he remained until his death in 1555. He was appointed *Stadtarzt* and in later years was several times *Bürgermeister*. Apart from a minor, though still valuable, work on weights and measures, he published nothing further until 1546, when the results of his many years of research in geology and mineralogy appeared in "De Ortu et Causis Subterraneorum".

Each treatise is preceded by a dedicatory letter to some friend or patron, and these letters often contain interesting information about Agricola himself. In one he lists the works he has yet to publish. Of these, some appeared in 1550, but the "De Re Metallica", the great work on mining and metallurgy so long awaited by his friends, was not issued until 1556, four months after his death. In the interim he had been called on to serve his patron, Duke Maurice, who became Elector of Saxony in 1547, in a diplomatic capacity. Maurice was a Protestant, and Agricola had remained a staunch Catholic during the stormy years of the Reformation. However, his writings reveal a tolerant outlook, and no doubt his wide knowledge and experience were valuable to the Elector, who sent him on various missions to the Emperor Charles V, Ferdinand, King of Hungary, and other princes. The rich mines of Saxony and Bohemia played an important part in the economy of Europe at that time, and probably Agricola's specialized knowledge made him a valuable intermediary. The Elector died in 1553, and was succeeded by his brother Augustus, who continued the patronage Agricola had previously enjoyed from Maurice. The text of the "De Re Metallica", dedicated to Maurice and Augustus, appears to have been completed by the end of 1550, but was long delayed, probably by the preparation of the several hundred woodcuts. In 1553 the completed book was sent to the Froben Press; but it was March 1556 before it appeared in print. Meanwhile, Agricola had died on November 21, 1555, from a sudden fever that lasted only four days. His position as a Catholic *Bürgermeister* in a fiercely Protestant town must have been anomalous, yet it is sad to learn his family were not allowed to bury him in the cathedral of Chemnitz, the town in which he had been so distinguished a citizen. Four days after his death, his body was conveyed to Zeitz, some forty miles away, and interred there, in the Catholic cathedral.

New editions and translations of his books, particularly the "De Re Metallica", continued to appear at intervals in the succeeding centuries, and a reprint of the Hoover translation was issued only a few years ago. No English translation of the "De Ortu" has yet appeared. For this reason it has been eclipsed in fame by the better known and beautifully illustrated "De Re Metallica". Nevertheless, it has every right to be regarded as a major scientific classic. Agricola brought to a study of the Earth and its constituents the touchstone of his own experience, and assayed the theories of earlier authors in the crucible of his profound knowledge of their writings, often finding the 'ore' to be of poor quality.

The "De Ortu" contains four new works and reprint of the earlier "Bermannus". Though eac treatise is self-contained, and the titles may appe unrelated, yet in fact their arrangement follows methodical plan. The first book, "De Ortu et Caus Subterraneorum", discusses the physical phenomen affecting the earth, in particular the part played b water; and Adams[4] comments that Agricola description of the earlier stages of erosion might we have been written in the twentieth century. Anothe of the topics in this treatise is the origin of or deposits, and here Agricola's reasoned view, tha ores were deposited from solutions in channels o fissures that had originated after the containing rock constitutes a remarkable advance on all previou speculations. The next two treatises deal with th constituents of the Earth. The first ("De Natur eorum quae effluunt ex Terra") discusses those which are vapours or liquids, and the second ("De Natur Fossilium") discusses solid bodies, for which he use for the first time, the word 'fossil'. The use of thi term to describe all substances dug out of the eart continued for well over two centuries, and it is onl since the beginning of the nineteenth century that i has been restricted to fossil organisms. The "D Natura Fossilium" is the first attempt at a systemati mineralogy, and in it Agricola describes man minerals for the first time. His classification of thes 'fossil' bodies has been described by Adams, but fact of considerable historical importance, which doe not appear to have been commented on by chemists is his recognition of the difference between chemica compounds ('mista') and mixtures ('composita'). The former, he states, are composed of two or more simple fossil bodies, so intimately mixed that "even in the smallest part there is not wanting any substance contained in the whole", and inseparable except by fire; whereas the components of the 'composita' can be separated not only by fire but also by water and sometimes by hand ("De Natura Fossilium", 1546, p. 185). This clear statement was made more than a century before that of Boyle in the "Sceptical Chymist". Boyle, incidentally, was familiar with the works of Agricola, whom he described as "the most classick author we have about mines".

Agricola's fourth treatise, on old and new mines and minerals ("De Veteribus et Novis Metallis"), contains a wealth of information concerning the situation of mines and the metals obtained from them. It is worth mentioning here that he gives a list of places in Cornwall where tin was worked, and refers to the meeting of miners from Cornwall and Devon every seven or eight years on "Hengenstendonus mons" (Hingston Down, twelve miles northwest of Plymouth) to discuss their affairs. This is later mentioned by Camden.

The "De Ortu" was translated into Italian in 1550, and other Latin editions appeared in 1558, 1612 and 1657; but the most useful edition for the student is the German translation, with many notes, which appeared during 1806–10. Unfortunately, this is as scarce as the earlier editions. An English translation would be most valuable and attract to the book the attention it undoubtedly merits. Meantime, one can say there is no question of placing Agricola among the great—he already stands there—but, unfortunately, almost unrecognized.

# ENERGY EXPENDITURE BY MAN

IT is notorious that there are fashions in science. The discovery of a new approach in any branch of work tends to direct attention to a restricted spect: not until the cream has been skimmed by means of the new technique is a balance restored. The study of nutrition is peculiarly liable to such endencies: the discovery of vitamins ushered in a ruitful and major preoccupation with the fundamental biochemical processes of cellular metabolism, nd so did the appreciation of the importance of race elements. Indeed, the earlier interest in proximate principles' was well-nigh ousted, and the dictum, "look after the calories in food and the other onstituents will look after themselves", fell into a robably well-deserved disrepute.

In nutrition, however, there is a very special sense n which a balance of interest must be preserved. As individuals and as communities we must balance the intake and expenditure of energy: the energy we give to the world in the work of our muscles and n the heat of our bodies we must recapture from ood. If expenditure exceeds income, the body of the individual wastes away, and on a national scale amine is abroad in the land; if intake is greater han expenditure, the individual will suffer from the ethal nuisance of obesity, and in the community here will be a glut and, in default of adequate methods of storage, a waste of food. Thus it is not ufficient to concern ourselves solely with the intake of food, to make available what we believe to be a afe margin in excess of requirements. If it comes o the point that we have to adjust our expenditure o income, we shall have to know how best to use he energy available to us. To combat obesity, the usual practice is to recommend a restriction in intake of food. But a human being is not a mere machine. He has genetical roots stretching far into the past when his body was adjusted to a life of hard physical toil. To restrict the intake of food is to throw his physiological processes out of gear, and it is better, f the food is available, to adjust the balance by ncreasing exercise. That demands some knowledge of the time-course of energy expenditure in different activities.

At the beginning of this century there was considerable interest in human calorimetry, both direct and indirect, this interest being well illustrated in the successive editions of Graham Lusk's classical book "The Elements of the Science of Nutrition" (1906–31). For the reasons already mentioned, nterest in calorimetry lapsed but now shows signs of a revival, in part due to the introduction of new apparatus and in part due to a realization that, after all, calories do matter. It was not inappropriate, therefore, that the Nutrition Society should arrange this year a symposium on the "Energy Expenditure by Man", which was held in the National Institute for Medical Research, Mill Hill, on October 15.

The first paper at the symposium, on the development of experimental methods for determining the expenditure of energy by man, was given by O. G. Douglas. He explained briefly the theoretical bases of calorimetry and followed the changes in technique, primarily in indirect calorimetry, from the early days of Regnault and Reiset[1] in 1849 to the present time. There have been no changes in fundamental principles and surprisingly few variants in the technical approach to the problem. The determination of the expenditure of energy depends on measurement of the gaseous exchange between a living organism and the atmosphere which surrounds it. The earlier techniques tended to be elaborate and cumbrous. The animal or human being was enclosed in a chamber through which air was circulated by a pump. The oxygen used by the animal was replaced from outside the system, and carbon dioxide absorbed within the system. Such techniques restricted gravely the living activities which could be studied, although brave attempts were made to study muscular activity in man by placing ergometers within large chambers. Indirect calorimetry was first successfully freed from the shackles of cumbrous laboratory equipment by Dr. Douglas's use of a large gas-tight bag to collect the expired air. Such a bag could be worn on the back, giving the subject very considerable freedom to carry out normal activities. The idea came to Dr. Douglas when watching an old-fashioned 'magic lantern': the gases for the lime-light were stored in large bags. No advance on this Douglas-bag technique appeared until 1940, when German workers introduced the Kofranyi–Michaelis respirometer (Max-Planck respirometer), which is a reversion to an old principle[2]. The expired air is passed through a light, dry flowmeter worn on the back like a haversack. As the expired air passes through the meter, small samples are withdrawn and collected for subsequent analysis.

Accurate methods of indirect calorimetry demand accurate gas analysis. Attempts have recently been made to replace the Haldane and similar types of apparatus by rapid physical methods; but these have not yet proved satisfactory.

H. S. Wolff described his light-weight integrating motor pneumotachograph[3], the principle of which is the same as that of the Max-Planck respirometer, except that the flowmeter employs a method new to calorimetry. The pressure of the expired air lifts a diaphragm from off the exit tube of the meter, and the lift of this diaphragm is proportional to the flow. The excursion of the diaphragm, by means of an electro-mechanical integrating device, allows the volume of expired air to be read on a veeder counter. In the latest models the volume of air expired can be recorded at a distance by transmitting impulses from the meter. A small pump draws a sample of expired air into a polythene bag, and the air in this bag is afterwards analysed. The pneumotachograph, with its associated equipment, is light, offers little back pressure to breathing and records faithfully rates of flow far in excess of those found during maximum expiration in strenuous exercise: with a face mask it can be worn for hours without distress, and thirst can be slaked with the mask in position. Observations have been made on men in the Army performing hard physical exercises. The way is thus open for a very complete survey of the expenditure of energy over long periods and in all walks of life.

In the afternoon session O. G. Edholm dealt with the value of measuring expenditure of energy in nutritional studies. These in the past have depended almost wholly on dietary surveys. Such surveys give reasonably accurate information on the income of energy, but give no indication of how the energy is spent. A review of the few surveys in which both intake and expenditure were measured shows good agreement on the average over a period of days. In a recent careful study[4], however, no correlation was found between individual daily intake and expenditure of calories: there was no correlation even between the mean expenditure of the group on any one day and the intake on that day. There was a correlation between the mean expenditure on one day and the intake two days later. Here is revealed an aspect of metabolism that is but imperfectly understood. The human body is able apparently to adjust its intake of food to an expenditure of energy which took place days before. Indeed, there is evidence that such belated adjustment may extend over a much longer period.

R. Passmore discussed the time-course of the daily expenditure of energy by human beings. With increasing mechanization in industry, with '*Homo sapiens*' becoming '*Homo sedentarius*', we tend, in our estimation of the severity of work, to place undue emphasis on the nature of the employment. Lying, sitting and standing occupy a large part of the twenty-four hours even for an active man. Roughly 500 Calories are spent asleep in bed, and 1,500 Calories in recreation and off-duty activities; and this seems to hold whether the occupation involves light or heavy work. Should there be a diminution in expenditure of energy in the period of recreation, as there may well be with advancing years, and if the appetite is not correspondingly curbed, obesity will rear its ugly head.

J. V. G. A. Durnin had the rather thankless task of talking about the influence of age on expenditure of energy. The report on calorie requirements by a committee of the United Nations Food and Agriculture Organization[5] suggests that the intake of calories at twenty-five years of age should be decreased by 7·5 per cent for every ten years beyond that age. There is very considerable criticism of this proposal; but the original suggestion, and all criticisms thereof, suffer alike from a practically complete lack of known facts. Information is badly needed in all communities where shortened working-hours for the young make an increasing demand for labour from the elderly. How do advancing years affect muscular efficiency, and what load can we place with safety on the age group 55–70 years? We do not know. A short pilot experiment showed that elderly men used more energy in walking than did younger men. The elderly, however, spent no more energy when the exercises were confined to the muscles of the arms. There is no reason why the metabolic processes in the muscles of the elderly should not be as efficient as those in younger people; perhaps neuromuscular control is not so efficient.

H. R. Noltie dealt with the expenditure of energy by athletes, a subject on which information is scanty: with the older techniques it was scarcely feasible to find with any degree of accuracy the expenditure of energy during the more strenuous and competitive forms of exercise. Golf is known to make comparatively modest demands on expenditure of energy, about 5 Cal./min.; fast walking, due to swinging of the arms, can be expensive in energy and even more expensive than slow running: sustained running at speed may demand 25 Cal./min. Swimming makes very great demands, and so does skiing. But the ski, from the point of view of energy expenditure, is, in all circumstances, more economical than the snowshoe. It is possible, too, to estimate the influence of style and of length of stride in running. Th 'fast start' is costly in terms of energy expenditur Thus, it is not beyond the bounds of possibility th athletes, trainers, and spectators with a financi interest in the outcome will all have ultimately t discuss athletic contests in relatively pure physio ogical terms.

General discussion after the final paper tended t focus on obesity, on its causation and on the ver real problem of the control of body-weight: restric the food intake and we are unhappy, increase exerci and we become all the hungrier. What is the cau of fatigue? What causes muscle soreness aft unwonted severe exercise? We have no answer These may come by future closer integration tha in the past between the physiological and biochemic approaches to the problems of nutrition.

# OBITUARIES

## Dr. W. K. Spencer, F.R.S.

Dr. William Kingdon Spencer, whose deat occurred at Ipswich on October 1 at the age o seventy-six, was a prominent figure in the world o education who, notwithstanding exacting officia duties, found time to carry out important researche on fossil starfishes and other Echinodermata. Th son of J. F. Spencer, formerly of Parkstone, Dorset he was born at Barrow-on-Soar, and spent his boyhood at Upper Hopton, Yorkshire, where his fathe had been appointed headmaster of the village school From Batley Grammar School (where he was a contemporary of Sir Owen Richardson) he gained demyship in natural science at Magdalen College Oxford, where he proceeded in 1898 after studyin for a short time at the University of Marburg Graduating in 1902 with first-class honours in zoology he was awarded the Burdett-Coutts Scholarship an began his researches on fossil invertebrates.

For a year (1903–4) Spencer held the post o lecturer and demonstrator in the University Department of Geology at Oxford, under W. J. Sollas. Hi career as a teacher of palaeontology soon terminated however, for in 1904 he was appointed to a post under the Board of Education, and before lon became the Board's chief examiner in science. In 1914 he was appointed inspector of schools for East Suffolk, where he guided the educational programme until his retirement in 1938 and was largely responsible for the very effective reorganization and the extension of the schools of that area which followed the Hadow Report of 1926. On retirement he lived for a time in Southern France and continued with his research work in the University of Montpelier. When France was overrun by the German army he escaped to Portugal and proceeded to South Africa, where he resumed educational work. After the War he again retired to France, first re-visiting Great Britain in 1953.

Spencer's first echinoderm paper, published by the Royal Society in 1904, dealt with the Palaeozoic genera *Palaeodiscus* and *Agelacrinus*, to the investigation of which he applied Sollas's technique of serial sections.

then turned to the Cretaceous Asteroidea, com-eting (1905–7) for the Palæontographical Society e monograph on that group which had been begun W. Percy Sladen in 1891–93. The evolution of ese forms was the subject of a subsequent paper in e *Phil. Trans. Roy. Soc.* (1913). His major work as his monograph of the British Palæozoic Asterozoa, n parts of which were published by the Palæonto-aphical Society between 1914 and 1940, when the ar made further progress impossible. Spencer's st work, in which he described and discussed the arliest known starfishes, which occur in the Lower rdovician of southern France and Bohemia, was ublished in 1951 by the Royal Society.

Spencer's work was concerned largely with ancient nd often indifferently preserved fossils; but he was n adept at getting the most out of his material and lways regarded the subjects of his researches rimarily as animals which had once lived in har-ony with their environment, and the functional gnificance of every structure of which demanded terpretation. The skilful reconstructions of these nimals and their organs, well depicted under his uidance by his artist, F. T. Jones (an Ipswich art aster), are a notable feature of his papers. He eceived his Oxford doctorate and the Lyell Award f the Geological Society of London in 1918, and in 931 was elected to the fellowship of the Royal ociety.

L. R. Cox

### Mr. R. B. Pilcher, O.B.E.

The name of Richard Bertram Pilcher, who died t his home in Northwood on October 1 in his eighty-econd year, will remain indelibly impressed on the ecords of two distinct professional organizations—he Royal Institute of Chemistry and the Chartered nstitute of Secretaries. A native of Patrixbourne, ear Canterbury, he was appointed clerk to the nstitute of Chemistry in 1892 and became suc-essively assistant secretary (1894), secretary (1895) nd registrar and secretary (1900–45). Pilcher had nown all the presidents from 1877 onwards, and rom his youth completely identified himself with the rofession and with its interests and aspirations. is tall, lean and dignified figure, with a hint of the scetic, due more to the delicate state of his health in early manhood than to any avoidance of the pleasures of life, was well known in scientific and official circles for many decades.

During the First World War the Institute became the chief agency whereby the various ministries and Government departments obtained chemists, and Pilcher, then secretary to the Glass Research Committee, was in constant demand. After the War he interested himself in the re-settlement of officers and other careers matters, serving on committees of the Ministry of Labour. He was appointed O.B.E. in 1920. He served as honorary secretary of the Chemical Council from its inception in 1935 until 1943. He became a member of the Parliamentary and Scientific Committee in 1935, and a vice-president in 1943. In 1952 the Institute paid tribute to his long service and abiding interest in the profession by admitting him as one of its first honorary Fellows.

An avid reader, fond of honest labour, and prone to contemplation, his pen never rested long. Several of his compilations became standard reference works, passing through a number of editions. Among these were "Official Chemical Appointments" (1906); the joint work "What Industry Owes to Chemical Science" (1918); and "The Profession of Chemistry" (1919). Having a keen interest in the history of chemistry, and particularly in chemical biography and iconography, he acquired a mass of manuscript material and a well-known collection of prints.

A Fellow of the (then) Institute of Secretaries in 1897, Pilcher served it as a member of council from 1908, as vice-president (1924–26) and as president (1926–27). He introduced the system of registered studentship, and was ever pleased to think that many thousands of young people had thereby increased their knowledge and worth to the community. He was also a past chairman of council of the Association of Men of Kent and Kentish Men.

Pilcher was intensely human and loved all growing things. This, perhaps, provides a clue to the main interests of his life—children and flowers; students and the history of science; the nurturing and service of two rapidly expanding professional organizations: in these matters his years did not weary him nor diminish his ardour. He is survived by his widow, Violet Frances, two sons and a daughter.

F. W. Gibbs

## NEWS and VIEWS

### oyal Society: Award of Royal Medals

H.M. The Queen has been graciously pleased to pprove recommendations made by the Council of he Royal Society for the award of the two Royal edals for the current year as follows: Sir Alexander odd, professor of chemistry, University of Cam-ridge, for his distinguished work in organic chem-stry; Prof. V. B. Wigglesworth, Quick professor of iology, University of Cambridge, for his distinguished xperimental contributions of outstanding value to any aspects of insect physiology.

### lectronic Engineering at Liverpool: Prof. J. D. Craggs

The Robert Rankin chair of electronic engineering n the University of Liverpool has been filled by the ppointment of Dr. J. D. Craggs, formerly reader in lectronic engineering. Dr. Craggs graduated in 1937 in the University of London and, after a year's research in the Mechanical Engineering Department at King's College, London, he was awarded a Department of Scientific and Industrial Research grant to enable him to work under the direction of Sir Charles Ellis on the development of a high-voltage accelerator for nuclear research. This work was carried out in the Research Department of the Metropolitan-Vickers Electrical Co. at Trafford Park, Manchester. In 1940 Dr. Craggs joined the research staff of this Company and continued to work on the accelerator until 1941, when he became concerned with the development of high-power spark modulators for radar. During 1944–45 he spent six months in the University of California, Berkeley, on studies of collision process connected with the uranium fission programme. In 1945 he returned to the Metropolitan-Vickers Research Department and was responsible for the construction of a 20-MeV. betatron. He also carried out work on the characteristics of electric sparks. In 1948 he joined the University of Liverpool as senior lecturer in electrical engineering and in 1949 he was promoted reader. Prof. Craggs's recent researches have been concerned mainly with electrical discharges. He has been an active member of the Institute of Physics and has been largely responsible for the formation of the Liverpool and North Wales Branch of the Institute. He is a member of a Ministry of Supply committee dealing with the application of electronic techniques to ballistic problems.

## Geology at St. Andrews :

### Dr. Charles F. Davidson, O.B.E.

Dr. C. F. Davidson has been appointed to the chair of geology in the University of St. Andrews, consequent upon the retirement in 1954 of Prof. D. E. Innes. Dr. Davidson is a graduate of that University (University College, Dundee), where he took his degree with first-class honours in geology and mineralogy; afterwards he was awarded the D.Sc. degree for a thesis on the geology of a part of South Harris, Outer Hebrides. Dr. Davidson has had a distinguished career with the Geological Survey of Great Britain and the Museum of Practical Geology, which he joined in 1934, and from which he has resigned his appointment as district geologist in charge of the Atomic Energy Division. He was first concerned with preparing exhibits for the new Museum in South Kensington which was opened in 1935, and his duties under Dr. W. F. P. McLintock widened his experience, especially in mineral determination. During the Second World War his attention was turned to preparing reports on overseas geology for the intelligence departments of the Services, particularly for the Naval Intelligence Division; in 1941 he compiled a report on uranium resources. It was this latter work which led to the setting up in the Geological Survey, with Dr. Davidson in charge, of a special department for investigations upon radioactive ores. Towards the end of 1945, the responsibility for research and development on atomic energy passed from the Department of Scientific and Industrial Research to the Ministry of Supply, and in 1954 to the United Kingdom Atomic Energy Authority. The work of the Survey's Atomic Energy Division, undertaken in conjunction with these various bodies, was directed towards the discovery and evaluation of radioactive mineral deposits capable of furnishing uranium and thorium ores to the British market. Dr. Davidson's success was marked both in field-work and in the development of appropriate laboratory techniques. In the course of his very extensive travels, he has visited areas in remote parts of the world to assess the economic potentialities of these important ores, and in several cases he has contributed to the scientific understanding of their genesis.

## Visit of Russian Scientists to Britain

The Royal Society, in association with the Soviet Relations Committee of the British Council, has arranged for a party of leading Russian scientists to visit Britain. The delegation is led by Academician A. N. Nesmeyanov, president of the Academy of Sciences, Moscow; other members of the delegation include Academician I. G. Petrovsky, mathematician and rector of the University of Moscow; Academician A. L. Kursanov, plant physiologist; Academician V. A. Kargin, physical chemist; and corresponding member of the Academy P. Ya. Kotchina, hydraulics engineer. Academician Nesmeyanov is a distinguish chemist and was director of the Institute of Orga Chemistry of the Academy of Sciences. He beca president of the Academy of Sciences in 1951, a has been a member of the Supreme Soviet of t U.S.S.R. since 1950. In addition to a number functions at the Royal Society, the delegation is visit Cambridge (November 18–20), where they w be the guests of Lord Adrian at Trinity Colleg Edinburgh (November 21–22), where their programm is being arranged by Sir Edward Appleton, princip and vice-chancellor of the University; and Oxfo (November 25–26), where Sir Cyril Hinshelwoo foreign secretary of the Royal Society, is arrangi a programme of visits. The Parliamentary a Scientific Committee will receive the delegation in th Houses of Parliament, and visits have been arrang to the National Physical Laboratory and Rothamst Experimental Station. The delegation will be th guests of the Royal Society at its anniversary dinn on St. Andrew's Day, November 30.

## Visit of British Atomic Scientists to the U.S.S.

A delegation from the United Kingdom Atom Energy Authority is on a six-day visit to the Sovi Union. Owing to heavy commitments in Gre Britain, Sir John Cockcroft, director of the Atom Energy Research Establishment, Harwell, has n been able to take part in the visit; the delegation therefore being led by Dr. B. F. J. Schonland, deput director at Harwell. The other members of th delegation are: Dr. Willis Jackson, representing th Royal Society and the British Nuclear Energy Co ference; Mr. B. D. Goodlet, head of the Engineerin Research and Development Division, Harwell; D J. V. Dunworth, head of the Reactor Physics Division Harwell; Dr. D. W. Fry, head of the General Physic Division, Harwell; Mr. A. A. Smales, head of th Analytical Chemistry Group, Harwell; Dr. L Rotherham, head of research and developmen Industrial Group, Atomic Energy Authority; an Mr. J. C. C. Stewart, director of the Technical Polic Industrial Group, Atomic Energy Authority. Th visit is the result of an invitation for a Britis delegation to visit the Soviet Union addressed to Si John Cockcroft at Geneva in August by the Sovie delegation to the United Nations Conference on th Peaceful Uses of Atomic Energy. Fifteen Sovie scientists were among the delegates to that Con ference which visited Harwell last August. Th programme of the visit to the U.S.S.R. includes a atomic power station, a powerful phasotron (a accelerating machine), the Lebedev Institute and th Institute of Geochemistry and Analytical Chemistry of the Academy of Sciences of the U.S.S.R.

## Astronomical Clock in York Minster

A memorial to airmen who fell while operating from bases in Northumberland, Durham and Yorkshire during the Second World War was unveiled in York Minster by H.R.H. the Duke of Edinburgh on November 1. The memorial contains an astronomical clock, designed by Dr. R. d'E. Atkinson and made under his direction in the workshops of the Royal Observatory. There are two main dials. On the west is a "Zodiacal" dial which shows the apparent motions of the sun. A large convex disk represents the horizon, as seen from York facing south, and a sun rises from behind this, passes across the sky and sets behind the disk again. The times of rising and setting are accurate to within one minute. The rays surrounding model sun are of such a length that when they appear behind the disk, twilight is approximately ding. In addition to its daily motion, the sun is own to move along a circle representing the iptic and it thus rises to the appropriate elevation any time of year. Solar time may be read from is dial and Greenwich Mean Time is shown on a l below. The equation of time may thus be tained as the difference between the dials. The er side of the memorial carries an "Astral" dial. is shows the daily apparent motion of the northern cumpolar stars. Sidereal time may be read from this l and it is also shown on dials on the "Zodiacal" e converted into degrees. The clock depicts events propriate to the latitude and longitude of York, d is intended to give a picture of the heavens as n by a navigator in an aircraft over the city. It housed with a Book of Honour in a walnut frame signed by Prof. A. E. Richardson and ornamented Mr. Maurice Lambert and Mr. H. J. Stammers.

## mospheric Pollution in Great Britain

In moving the second reading of the Clean Air ll in the House of Commons on November 3, the rliamentary secretary to the Ministry of Housing d Local Government, Mr. W. F. Deedes, said that e Government believes that the necessary replace-ent in the black areas scheme of about 19 million ns of house coal by smokeless fuels can be gradu-ly achieved over fifteen years. The Government s accepted the Beaver Committee's recommenda-ns that the most efficient practicable method of moving sulphur should be used in power stations or near populated areas, and research into this oblem is being pressed forward. He emphasized at the rate of progress may be limited by the fficulty of finding the technical staff required by cal authorities for the discharge of their additional sponsibilities. Mr. Deedes announced the Govern-ent's acceptance of the Beaver Committee's commendation for the establishment of a Clean ir Council, and in replying on the debate the inister of Housing and Local Government said that is the Government's intention to make the Bill as fective, tight and strong as possible consistent with hat is practicable. He is prepared to consider the clusion of a general introductory clause stating at clean air is a national policy, though he does t think it would add anything to the Bill, and also make the appointed day, for the purpose of the ven-year period allowed for the modification of uipment, the day after the passing of the Bill. In gard to research, he emphasized the work already ing carried out by the Department of Scientific d Industrial Research and referred to the con-ruction by the Central Electricity Authority of a ll-scale pilot plant for extensive trials at a power ation. Mr. Sandys promised to consider sym-athetically at a later stage any amendments likely make the Bill a more effective instrument to adicate a great social and economic evil, a enace to public health and a source of waste and estruction.

## entific Library Centre in London

In a written answer to questions from three embers of the House of Commons on November 1, r. J. R. Bevins, parliamentary secretary to the inistry of Works, as representing the Lord President the Council, stated that the proposals for improved ientific libraries referred to in the eighth annual report of the Advisory Council on Scientific Policy are at present being considered by the Departments concerned. As these projects involve considerable capital expenditure, and the reference library scheme is bound up with wider questions affecting the Patent Office, Mr. Bevins regretted that he was not yet able to make a statement. In a further reply on November 8, Mr. Bevins said that the capital cost of a new building to house both the Patent Office and its library, extended to provide a National Reference Library, was estimated at rather more than £2,000,000.

## Economics of the Press in Great Britain

The broadsheet on the "Balance Sheet of the Press", issued earlier this year by Political and Economic Planning (*Planning*, **21**, No. 384; 1955. Pp. 14; 2*s*. 6*d*.), is of particular interest in view of the recent announcement by the Board of Trade that control of newsprint in Great Britain is to end next year. The broadsheet directed attention to great changes which are impending in the organization of the British Press. It is the first of a series which sets out to examine these problems, and it throws some light on the critical reception of the Government's decision by the Newsprint Supply Company, which is desirous that some form of voluntary rationing should continue to safeguard the weaker papers, as the ending of control does not mean that supplies will then be adequate to meet demands. On this point the broadsheet suggests that the high price of newsprint is likely to prevent daily newspapers from reaching their pre-war size, although twelve-page papers are probable. A considerable rise in world demand is anticipated during the next decade, and substantially increased production is planned in spite of the fact that world supplies are severely limited in the immediate future; the provision of more newsprint during the next few years depends on renewed contracts with Canada, although, later, increased supplies may be available from non-dollar sources.

Between 1937 and 1947 the circulation of London and provincial dailies rose by more than ten million and that of Sunday newspapers by fourteen million, compared with an increase in population in the period of 2·6 million. Magazines and periodicals had a circulation of about twenty-six million in 1938 and probably more than forty million in 1952. Press advertising in 1954 was estimated at about £160 million out of a total advertising expenditure of £280 million, and, of this, 38 per cent was in provincial newspapers, 24 per cent in national newspapers, 21 per cent in magazines and periodicals and 16 per cent in trade and technical journals. The provincial newspapers, posters and the smaller-circulation magazines are expected to lose most to television advertising. As regards the future, costs in all departments of newspaper production are expected to continue to rise, and the total circulation of the national papers is probably near its limit. Total sales revenue is unlikely to be increased by raising the price of the daily paper; unaccompanied by a larger paper, it could cause a substantial fall in sales. In view of competition from television advertising, substantial increases in advertising-rates are unlikely, nor, while papers remain at their present size, can the 33 per cent of their space devoted to advertising be increased. Much could be done, however, to eliminate waste of man-power and materials, and the broadsheet suggests that both management and labour should pay greater attention to the increase of efficiency in this way.

## Cortisone and Corticotrophin

The November issue of *The Practitioner* is devoted to a consideration by a number of authorities of the value and dangers of the hormones cortisone and corticotrophin (ACTH). Until recently, supplies of both these drugs in Great Britain were not adequate; but now there are good reasons for believing that supplies of them will soon be enough to satisfy all needs. They are, in most instances, used empirically, because we do not yet know enough about how they act; but their value in carefully selected cases is very apparent from Dr. C. L. Cope's article on their pharmacology and from the other articles by experts who discuss their uses for treating chronic rheumatic diseases, gout, rheumatic fever, certain diseases of the skin, the eye, the endocrine glands and blood, and for asthma, or as an aid to surgery. To summarize these articles in a brief review is impossible, and would be dangerous; indeed, it would not be wise to epitomize, or take out of the context, the scope and content of Prof. E. J. Wayne's contribution on the dangers and complications of the use of these drugs. Nevertheless, an indication of the general position can be gathered from the opinion expressed on the first page of the issue that "the practitioner will not go far wrong if he continuously bears in mind the advice given by Prof. Wayne that, in cases of doubt, it is better to be cautious in deciding to give these drugs". Prof. Wayne, however, also says that fifteen years ago the text-books "devoted pages to the side effects of sulphonamides, but they are still used in considerable quantities and with good effect".

## The South African Museum, Cape Town (1855–1955)

The centenary of any organization is an appropriate time to publish details of its origin and progress. The South African Museum at Cape Town has thus just published an admirable booklet to celebrate that event (pp. 23+4 plates; 1955). As with so many museums of the early and middle nineteenth century, it was founded on the pattern of the British Museum in London. It is indeed fortunate in that as early as 1855 the trustees realized that the Museum should be a place of education combined with recreation and also a centre of research on the natural products of South Africa. It was not until 1897 that the Museum acquired a second and more adequate building, and now it is rightly suggested that the centenary should be marked by additional galleries. This would enable the greatly increased collections to be more properly preserved and the display to be modernized. The booklet gives a brief description of the principal acquisitions since 1855, and an important section deals with the field-work that the Museum has been able to organize.

## British Nuclear Energy Conference: Meeting in London

The British Nuclear Energy Conference, which has been formed by the Institutions of Civil, Mechanical, Electrical, and Chemical Engineers and the Institute of Physics (see *Nature*, June 11, p. 1023), will hold its first meeting in the form of a lecture symposium, to be held at the Institution of Civil Engineers (Great George Street, London, S.W.1) on November 30 (2.15–8.15 p.m.) under the chairmanship of Sir Christopher Hinton. Lectures will be delivered as follows: the United Kingdom Atomic Energy Project (Sir John Cockcroft); the place of nuclear energy in United Kingdom power development (V. A. Pe and J. C. Duckworth); the use of research reacto in nuclear power development (H. J. Grout); a health and safety in a nuclear power industry (A. Maclean and Dr. W. H. Marley). The papers will published in the new *B.N.E.C. Journal* of the Co ference (see *Trans. Inst. Chem. Eng.*, 33, No. Oct. 1955). Attendance at the symposium will confined to members of the five member bodies co cerned, and those who wish to attend should write soon as possible to the secretary of their particul professional body.

## Atomic Energy Exhibit at British Industries Fair

The "Atoms for Britain" exhibition, shown Geneva during the Conference on the Peaceful Us of Atomic Energy, will be seen for the first time Britain at next year's British Industries Fair. It to be presented by the U.K. Atomic Energy Authori and will be a major feature in the electrical a electronics sections of the Fair at Olympia, Londo during April 23–May 4. The exhibition, which cove 7,000 sq. ft., will show Britain's progress in ha nessing nuclear power and in using atomic energy industry, agriculture and medicine. The resear carried out at Harwell will be illustrated by larg scale models, photographs and diagrams. One of th models will be of DIDO, the 'heavy-water' researc reactor which will be completed by next summer. model of Britain's first atomic power station no being built at Calder Hall, Cumberland, will also on show. This station, which is scheduled to sta feeding electricity into the national grid at the e of next year, is the first of twelve to be built Britain during the next ten years. Another mod on display will be of a more advanced and expe mental type of power unit now under constructi at Dounreay, Caithness. The uses of radioacti isotopes will also be shown.

## First International Congress on Documentation Applied Chemistry

The first International Congress on Documentati of Applied Chemistry will be held in London duri November 22–25, at the Institut Français, Queen berry Place, South Kensington. The Congress under the patronage of the International Union Pure and Applied Chemistry, and the president honour is Lord Cherwell, Dr. Lee's professor experimental philosophy in the University of Oxfor who will open the first session. The Congress confined to one particular field, namely, applie chemistry, and although not the first of its kin it is the first conference at an international lev at which a serious attempt has been made t bring together librarians and information officer on one hand, and the applied chemists, who u the information they supply, on the other. O November 23 two sessions will be held on the inte national and national scenes, respectively, with D L. H. Lampitt and Sir Alfred Egerton as chai men. On November 24 two sessions will be devote to particular problems, with Prof. E. Velande (Sweden) and Prof. A. Nasini (Italy) as chairme On the last morning, the Congress, with Prof. W Albert Noyes (United States) as chairman, will loo to the future. At the final session in the afternoo there will be an open discussion on the problem raised during the various sessions and a paper givin a summary of the proceedings; a valedictory addre will be given by Sir William Ogg, director of th

Rothamsted Experimental Station and chairman of the Congress Council. A registration fee of 2 guineas will be charged, payable to the Honorary Secretary of the Congress at 56 Victoria Street, London, S.W.1, from whom further information can be obtained.

## Aluminium in Shipbuilding

A symposium on "The Use and Welding of Aluminium in Shipbuilding", organized by a joint committee representing the Institute of Welding, the British Welding Research Association, the Institution of Naval Architects, the British Shipbuilding Research Association and the Aluminium Development Association, will be held in the Weir Lecture Hall of the Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1, during December 7–8. The symposium will consist of four sessions on, respectively, welding processes and techniques; materials and design; applications; and applications and economic factors. Admission to the symposium for he discussion of the papers to be presented is free. The papers will be published before the symposium, and a complete set can be obtained on payment of a registration fee of 4 guineas. The full proceedings will be published later and offered for sale by the Institute of Welding. Further information can be obtained from the Secretary, Institute of Welding, 2 Buckingham Palace Gardens, London, S.W.1.

## International Wool Textile Research Conference

The proceedings of the International Wool Textile Research Conference held in Australia in August and September (see *Nature*, October 15, p. 712) are to be published in five volumes. The Commonwealth Scientific and Industrial Research Organization is making a special pre-publication offer at a price of £A10 per set of five volumes, or £A2 per volume for Volumes *A–D* and £A4 for Volume *E*. The titles of the volumes are: Volume *A*, "Histology of Wool and Hair and of the Wool Follicle"; Volume *B*, "Chemical Physics and Physical Chemistry of Wool and Proteins"; Volume *C*, "Chemistry and Biochemistry of Wool Proteins, Peptides and Amino Acids"; Volume *D*, "Physics of Wool and other Viscoelastic Fibres"; Volume *E*, "Wool Technology". The ordinary price will be £A25 for the five volumes, and the reduced price is possible only for orders which are received before printing commences. Order forms are available from: Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2.

## University of Glasgow

The following have been appointed lecturers in the University of Glasgow: G. W. Crosbie (biochemistry); N. G. Waton (experimental pharmacology); N. Grassie (macromolecular chemistry); J. Aitchison (mathematics); H. A. de Borde, B. H. Bransden, D. Dixon and W. S. C. Williams (natural philosophy); I. A. Boyd and Ann B. MacNaught (physiology), and L. M. Kellas (veterinary histology and embryology). Dr. A. Bhati has been appointed to an Imperial Chemical Industries, Ltd., fellowship in chemistry. A course in nuclear engineering, consisting of forty lectures and about twenty-five hours of practical work, is now available in the University for final-year students in engineering; it is being run by the Department of Natural Philosophy. A new petrochemical laboratory has been added to the Geology Department, and some of the space vacated by the Chemistry Department in the main University building is being taken over as an extension by the Geography Department. For the present session, 343 new students (273 men and 70 women) have been admitted to the science departments, compared with 287 in 1954. In the University as a whole, the total number of matriculated students has increased by about a hundred to 5,679.

## University of London

The title of professor of biology in the University of London has been conferred on G. E. H. Foxon in respect of his post at Guy's Hospital Medical School, and that of professor of geography in the University of London on A. E. Smailes in respect of his post at Queen Mary College. The following have been appointed to University of London readerships tenable at the institutions indicated: Dr. P. M. Butler, zoology at the Royal Holloway College; Dr. S. W. Hinds, public health at the London School of Hygiene and Tropical Medicine; N. P. W. Moore, mechanical engineering at the Imperial College of Science and Technology; and Dr. R. K. S. Wood, plant pathology at the Imperial College of Science and Technology.

## Announcements

Dr. J. F. Lockwood, master of Birkbeck College, has been elected vice-chancellor of the University of London for the remainder of the university year 1955–56, in succession to Prof. H. R. Robinson, who has resigned on medical grounds.

The Ellen Browning Scripps Fellowship for 1955–56 has been awarded to Dr. Gordon W. Ballmer. The Fellowship is awarded by the San Diego Zoological Society, California, and is for research in any field of biology, a stipend of 3,500 dollars for a ten-month period being provided, together with full facilities for work at the San Diego Zoological Gardens. Dr. Ballmer, who is a graduate in zoology of the University of Michigan, Ann Arbor, will study carbohydrate metabolism in the Testudinata.

Mr. S. L. Huthnance, at present county agricultural officer for Berkshire, has been appointed deputy provincial director for the West Midland Province of Britain, in succession to Dr. D. H. Robinson, who was recently appointed provincial director.

The ninth meeting of the European Association of Exploration Geophysicists will be held in London, at Church House, Westminster, during December 7–9. Further information can be obtained from the British representative, J. E. R. Wood, British Petroleum Co., Ltd., Kirklington Hall, nr. Newark, Notts, or from the Association itself at 30 Carel van Bylandtlaan, The Hague, Holland.

The Scientific and Technical Group of the Royal Photographic Society is arranging a conference on "Photographic Science and Technique", to be held on December 3, in the Arthur Worthington Hall of the University of Manchester (Dover Street, Chorlton-on-Medlock, Manchester 13). Seven papers will be read. It is hoped to make a visit in the evening to the Shirley Institute. The conference will be open to the public. Further information can be obtained from R. E. Withrington, 49 Kensington Avenue, Manor Park, London, E.12.

In his review of Dr. Pollitzer's book on plague, which appeared in *Nature* of October 1, p. 615, Dr. E. Ashworth Underwood wrote on line 7: "Dr. Pollitzer, the only surviving author". Dr. Wu Lien-teh is in fact alive and still very active in other capacities.

# PHYSICAL CHEMISTRY OF ENZYMES

## FARADAY SOCIETY DISCUSSION

THE Faraday Society held a discussion on "The Physical Chemistry of Enzymes" during August 10–12 in the Department of Physiology, University of Oxford. At the suggestion of the chairman of the organizing committee, Prof. F. J. W. Roughton, the time of the meeting was arranged so that it followed the International Congress in Biochemistry. As a result, a large number of biochemists from the Congress were able to be present at the Faraday Society discussion, and the total attendance was 244. Twenty-nine papers concerning a wide field of enzyme topics were discussed, and a great many valuable contacts were made between enzyme biochemists and physical chemists interested in the enzyme field. The chair at the opening session was taken by the president of the Society, Prof. R. G. W. Norrish, and the introductory paper was given by Dr. M. Dixon, whose lucid exposition of the present position of the field set the pattern for the subsequent discussion.

Dr. Dixon pointed out that of approximately four hundred and fifty known enzymes, all of them protein molecules, about a hundred have been obtained in crystalline form. He noted that enzyme studies include both protein properties and catalytic properties, and that most of the papers before the meeting were concerned with the latter aspect. A great many enzyme reactions fall into the general class of group transfer reactions, and the requirements of specificity suggest in many cases a close fit between enzyme and substrate over a patch 15–20 A. in diameter. Such an active patch might be associated with a particular folding of polypeptide chains in the surface of the protein, giving rise to a characteristic arrangement of side-chains. Passing to problems of kinetics, Dr. Dixon discussed the various developments of the basic Michaelis–Menten equation, which supposes enzyme ($E$) and substrate ($S$) to combine to form a complex ($ES$) which decomposes to the product ($P$), with the rate-constants given:

$$E + S \underset{k_2}{\overset{k_1}{\rightleftharpoons}} ES \xrightarrow{k_3} P$$

He referred to the various ways of identifying the rate-determining step for the overall enzyme reaction, later treated in detail by several contributors to the discussion. He showed how the effect of $p$H on enzyme velocity may lead to a knowledge of the $pK$ of ionizing groups in the active site, and also described the use of isotopes in investigating the sequence of bonds broken in enzyme reactions.

### Characterization and Physical Properties

The papers in the section on "Characterization and Physical Properties" were concerned entirely with soluble enzymes. It is well known that a crystalline protein is not necessarily homogeneous. In cases where two or three species are present, they may frequently be separated by electrophoresis or sedimentation, the first technique depending on differences in charge (therefore ionizing groups) and the second on molecular weight. A single homogeneous protein diffusing across a boundary according to Fick's law sets up a concentration gradient/distance relationship of Gaussian type, but a mixture of proteins leads to departures from this curve. A paper by R. L. Baldwin, L. J. Gosting, J. W. Williams and R. A. Alberty (Wisconsin) described first how th diffusion method has been increased in sensitivit until 0·1 per cent impurity is detectable in crystallin albumins, using an interference-fringe method. study of the reversible spreading of electrophoreti boundaries can detect differences of one electroni charge between protein molecules.

V. Massey, W. F. Harrington and B. S. Hartle (Cambridge) have 'labelled' enzymes with an organi dye molecule, and compared the inhibiting effect o the dye with measurements of fluorescent depolarization and sedimentation constant. The evidence is tha the first dye molecules taken up combine with a active group of the enzyme, and that the same grou is involved in chymotrypsinogen, chymotrypsin and di*iso*propylphosphofluoridate-chymotrypsin. The grou concerned is therefore probably the enzyme-substrate-binding group, and it is of great interest that th group is free in the precursor molecule. Since the di-*iso*propylphosphofluoridate site is also essential for catalytic activity, this is associated with activation of the enzyme-substrate complex:

$$E + S \rightleftharpoons ES \rightarrow ES^* \rightarrow P$$

According to H. Neurath and W. J. Dreyer (Seattle), the conversion of the precursor chymotrypsinogen into the active enzyme chymotrypsin involves the hydrolysis of a peptide bond between arginine and an *iso*leucine residue, a similar process, but involving lysine, occurring in the trypsinogen-to-trypsin change.

In the living cell the enzymes are in contact with lipoidal membranes which may modify their activity, and this aspect was considered by M. J. Fraser, J. G. Kaplan and J. H. Schulman (Cambridge), who found negatively charged oil–water emulsions to adsorb positively charged catalase very strongly, the first eight monolayers of catalase being completely inactivated. A positively charged oil droplet, however, only adsorbed one monolayer of enzyme, which still retained some activity. Liberation of catalase from living cells has been found to give an eighteen-fold increase in activity in agreement with the emulsion findings. A paper by L. Robert and J. Polonovski (Paris) dealt with the liberation of xanthine oxidase from the fat droplets in milk by various methods. If enzyme activity can be modified by adsorption on membranes, then a new dimension is added to enzyme biochemistry within the cell.

### Kinetics and Mechanism

The second half of the meeting was devoted to a consideration of "Kinetics and Mechanism". A paper by J. G. Kirkwood (Yale) advanced the view that, in addition to the usual dispersion and ion–dipole forces, the fluctuation of proton configuration on the protein part of an enzyme will lead to an attractive electrostatic force on a substrate molecule at its surface. If now in the process of forming the activated complex ($ES \rightarrow ES^*$) there is an increase in dipole, then there will be a lowering of $\Delta G^*$, the free energy change of activation, that is, a catalytic action on the substrate. The discussion turned on how far this mechanism will predict the details of the activity/$p$H curves observed in practice—it accounts for the maximum observed in terms of only one arbitrary constant. A paper by K. J. Laidler (Washington, D.C.) gave criteria for deciding the relative magniudes of $k_1$, $k_2$ and $k_3$, and then tabulated $\Delta S^*$ entropy of activation) in the various cases. Laidler stressed an interpretation of entropy changes in terms of water-release effects following polarity changes in the activation process.

E. L. Smith, B. J. Finkle and A. Stockell (Utah) discussed the hydrolytic action of purified papain. They found the Michaelis constant $K_M$ ($K_M = k_2 + k_3/k_1$) and $k_2$ to vary with $p$H in a rather complex manner, $p$H optima depending upon temperature. The explanation given was that $k_2$ involves a sequence of steps,

$$E + S \rightleftharpoons (ES)_1 \rightarrow (ES)_2 \dashrightarrow (ES)_n \rightarrow P$$

and that the rate-determining step changes with temperature. The papain molecule contains an SH-group in the active site which may function by forming a thiol ester with the carbonyl group of the benzoyl arginine amide substrate. R. Lumry and E. L. Smith (Utah) prefer to consider the Michaelis equation simply as the general equation for the conservation of enzyme molecules, replacing $K_M$ by $\beta/\alpha$ and $k_2$ by $\beta$, and then seeking correlations between $\alpha$ and $\beta$ for the carboxypeptidase system for a range of variables, $p$H, solvent, etc. These authors stressed the need for a proper statistical treatment of the experimental results.

Four papers were presented on esterases. J. A. Cohen (Netherlands) has worked with acetyl cholinesterase and chymotrypsin and confirmed the studies of Shaffer and Summerson, using di-*iso*propylphosphofluoridate labelled with phosphorus-32. Reaction of the enzyme with this substance and subsequent hydrolysis yields phosphoserine; but it seems unlikely that serine is the initial site of attack, as $pK$ evidence points to histidine as the active site. It may be that the di-*iso*propylphospho-groups migrate from an initial histidine site to serine, and B. J. Jandorf *et al.* (Maryland) presented evidence that ageing chymotrypsin–di-*iso*propylphosphofluoridate makes it more and more resistant to reactivation by nucleophilic agents. I. B. Wilson (Columbia), in his paper, pictured the active site of acetyl cholinesterase as an anionic site next to an esteratic site. While nucleophilic agents are normally used for removing the di-*iso*propylphospho-group from the esteratic site, he found that incorporation of a cationic group in the agent much increased its speed of action. Presumably the cationic group is adsorbed on the anionic (enzyme) site and helps the nucleophilic attack. Bergmann compared monoquaternary and diquaternary inhibitors with acetylcholinesterase and butyrylcholinesterase, and on this basis concluded that the former contains two anionic sites, the latter one, and ordinary liver esterase none.

Two papers were contributed on bacterial hydrogenase, a particulate enzyme. That by A. Couper, D. D. Eley and A. Hayward (Bristol and Nottingham) found the $p$H$_2$ conversion to be about five times faster than either $D_2 - H_2O$ or hydrogenation reactions. The true activation energy for the conversion was considered to be 10 k.cal., and a dehydrated film of bacteria was inactive but became active again on rehydration. A. I. Krasna and D. Rittenberg (Columbia) have found that, in the $H_2/D_2O$ exchange, HD was the first species to appear in the gas phase, and they put forward a scheme for the conversion involving interaction of an enzyme hydride ($E$H) with water,

$$E\text{H} + \text{H}_2\text{O} \rightleftharpoons E\text{OH} + \text{H}_2$$

D. E. Koshland (Brookhaven) showed how isotope exchange may be used for excluding possible mechanisms of action of transferring enzymes, illustrating his methods with experiments on $5^1$-nucleotidase. In this case he was able to exclude an enzyme-phosphate complex as an intermediate in the hydrolysis of adenosine monophosphate. It would seem that both adenosine monophosphate and water must be adsorbed on the enzyme, and also that the adenosine serves to fix the orientation of active groups. R. K. Morton (Melbourne) has investigated the transferring activity of phosphatases with acceptors such as glucose, finding a competition between transferring and hydrolysis reactions, and from this concluding that there is a definite water-site in the enzyme.

G. Weber (Sheffield), in a theoretical paper, considered the transfer of energy between separated enzyme and substrate molecules, and from the protein part of an enzyme-substrate complex into the substrate molecule. He concludes that the latter is probably the way that the enzyme-substrate activated complex is formed. A theoretical paper by A. G. Ogston (Oxford) considered equilibria between enzyme, enzyme-substrate, enzyme-inhibitor and enzyme-substrate-inhibitor complexes and then discussed the free energy of activation $\Delta G^*$ for various limiting conditions. H. Gutfreund (Cambridge) outlined the results of applying the analysis of Gutfreund and F. J. W. Roughton to the initial non-stationary state of several hydrolytic enzymes, using a Gibson stopped-flow apparatus. This method leads to values of $k_1$ for formation of the enzyme-substrate complex, and a later paper by E. C. Slater (Amsterdam) showed how conventional kinetic data may also lead to values of $k_1$. Generally, $k_2$ is not simply a monomolecular decomposition, but is really $k_2{}^1X$, where $X$ is water or some other acceptor. By examining a given enzyme with a range of acceptors, a relation between apparent $K_m$ and $V_{\text{max.}}$ ($= k_2e$) is obtainable, which leads to values of $k_1e$ and $k_2e$, where $e$ is the enzyme concentration.

Sir Rudolph Peters (Agricultural Research Council) compared the toxic properties of the natural fluorocitric acid with the synthetic material, containing unnatural isomers. The synthetic material is the more toxic with soluble aconitase, and less toxic with the mitochondrial preparation, which Sir Rudolph tentatively attributed to stereochemical differences between the preparations. Stereochemistry was a main consideration in the paper by B. Vennesland (Chicago). She has found that deuterated diphosphopyridine nucleotide is stereospecific when formed enzymatically, but not when formed by chemical reduction, showing that in the enzyme case the deuterium atoms must add on to the same side of the pyridine ring.

A further two papers dealt with enzymatic reductions by the reduced diphosphopyridine nucleotide. H. Theorell (Stockholm) examined the kinetics of reduction of aldehyde using liver alcohol dehydrogenase. He has established that the reduction goes through the binary complex of reduced diphosphopyridine nucleotide and liver alcohol dehydrogenase and has obtained values for the four rate-constants concerned. In the case of yeast alcohol dehydrogenase, it was mentioned that a ternary complex is involved. I. W. Sizer and A. Gierer have started from Westheimer's proof, using deuterium labelling, that in the transfer from reduced diphosphopyridine nucleotide to acetaldehyde the hydrogen atom goes to the carbon of the acetaldehyde. Arguing from the observed effects of $p$H on velocity and $K_m$, they conclude that the second hydrogen atom is provided by the enzyme and not by an $H_3O^+$ ion from the solution.

The last three papers at the meeting were concerned with iron porphyrin systems. P. George and G. I. H. Hanania (Cambridge) discussed titration data for myoglobin derivatives, concluding that only one hæm-limited acid group is present. Q. H. Gibson (Sheffield) and F. J. W. Roughton (Cambridge) described work on evaluating velocity constants for the addition of four carbon monoxide molecules successively to the four iron atoms of the hæmoglobin molecule, and similar equilibrium constants with oxygen. The solutions for the equations were obtained using electronic computation. In the absence of differences in reactivity, the velocity constants should be in the ratios 4, 3, 2, 1, where 1 refers to addition of the fourth molecule. In fact, the first three constants do not vary much from this expectation, but the fourth constant is enhanced eighty-fold. Gibson described the experimental method used as an adaptation of the flash photolysis technique of Norrish and Porter. B. Chance (Pennsylvania) described work on determining pseudo first-order velocity constants for the steps of the cytochrome chain occurring within the cell,

$$O_2 \xrightarrow{k_1} \text{cyta}_3 \xrightarrow{k_3} \text{cyta} \xrightarrow{k_5} \text{cytc} \xrightarrow{k_7} \text{cytb} \rightarrow \text{fp} \rightarrow \text{DPN} \rightarrow \text{S}$$

where fp denotes flavoprotein. Using different wavelengths, it was possible to follow the concentrations of the individual components by spectrophotometric means, and Chance concludes that there is a graded series of reaction-rates from left to right along the chain. This fact must be taken into account in any proposed mechanisms for electron transport. Work was also described with nitrate as oxidizing agent and with photosynthetic systems.

It has only been possible to mention points from each paper in the above brief account, and reference to the lively discussions which followed the papers has had to be omitted. The Faraday Society is to be congratulated on its foresight in bringing together biochemists and physical chemists in what has proved to be one of the most stimulating discussions in recent years.

D. D. ELEY

# PULMONARY CIRCULATION AND RESPIRATORY FUNCTION

## SYMPOSIUM IN DUNDEE

DURING September 15–16, Queen's College (University of St. Andrews), Dundee, organized a symposium on "Pulmonary Circulation and Respiratory Function", which was probably the first of its kind to be organized by a university institution. It was an interesting experiment because the papers read covered a wide range of subjects and the audience was drawn from a wide range of interests—namely, physicians and surgeons, pathologists, physiologists and applied physiologists. The interest taken in the symposium, to judge from the size and enthusiasm of the audience, was in large part due to the development during recent years of human cardio-respiratory studies all over the world. Much of the work discussed has not yet been adequately assessed from the point of view either of its scientific reliability, or its value in assisting in diagnosis.

Dr. de Burgh Daly (Institute of Animal Physiology, Cambridge) opened the programme with a paper o "Pulmonary Vasomotor Nerve Activity and it Possible Functional Significance". He pointed ou that a great deal of careful experimental work o animals is needed to demonstrate the existence o changes in pulmonary vascular resistance due to th action of vasomotor nerves. Valid conclusions ca only be reached from the results of animal experiments where factors such as the pulmonary ventilation and circulation can be controlled adequately Without these precautions, passive changes in pulmonary flow, pressure and resistance may obscur the demonstration of active vasomotor changes The demonstration of vasomotor responses, as Dr Daly remarked, does not imply that they play any part in the responses of the intact animal. The conditions of these experiments are often highly artificial. In the human subject, the control of all the variables is so difficult a task that great care should be exercised in drawing any conclusions about the existence of an independent control of the pulmonary blood vessels. Even in animal experiments, the site of action of pulmonary vasomotor fibres is uncertain.

Dr. K. W. Donald (Department of Medicine, Birmingham) gave a paper on "The Pulmonary Circulation in Health and Disease", from which one gathered that the difficulties in designing appropriate experiments, to which Dr. Daly directed attention, must apply also to experiments on man. For example, though there is agreement that the pulmonary vascular resistance to blood flow is small, the effect of exercise on the resistance of the blood vessels is in dispute even in healthy subjects. Some workers consider that the resistance decreases during exercise, whereas others find that the pulmonary vascular bed acts passively in conducting blood. On this matter, there appears to be no agreement about the facts, so it is superfluous to consider whether any question of vasomotion is involved. Dr. Donald concluded that there is as yet no clear evidence of vasomotor activity in human lungs. The problems of physiology posed by disease are numerous and largely unsolved, and some of these were reviewed.

Prof. A. A. Liebow (Yale) stressed the importance of the bronchial arteries, the azygos and other systemic veins in the circulation. His experiments showed that it is possible to ligate the pulmonary arteries and veins and yet have a collateral circulation of oxygenated blood (the extent of which increased in the course of a few months) adequate to maintain life. He demonstrated these points with the aid of casts of the blood vessels and suggested that his experiments may have some application in the treatment of certain developmental abnormalities of the heart and large vessels, and in coronary occlusion. Sir Russell Brock (Guy's Hospital, London) directed attention to the studies which have been made on the physiology of the infundibulum of the right ventricle. Clinical observation both before and at operation in cases of Fallot's tetralogy, for example, make it essential that detailed information should be available about the conditions existing in the infundibulum before a successful operative result can reasonably be expected. He illustrated his thesis by reference to a number of clinical cases.

Prof. J. Gough (Welsh National School of Medicine, Cardiff) reported on the results of post-mortem examinations made in his Department on Welsh coal miners. There is a high incidence of deaths attributable to cor pulmonale and massive pneumoconiosis.

Prof. Gough described the vascular changes in the ungs in this disease and also indicated the value of tudying the grosser pathology of the lungs with the ld of paper-mounted sections. Prof. P. R. Allison Oxford) described his technique of studying left atrial pressures by puncture of the atrium with a needle inserted down a bronchoscope. His objective was an attempt to distinguish, on the basis of the pressure tracings he obtained, between cases of mitral tenosis and mitral incompetence. The results showed sharp separation between the two groups, but this clear-cut result (as became apparent in the later iscussion) may have been in part due to the selection of patients for a surgical opinion. The view was xpressed by Dr. P. Wood (Institute of Cardiology, London) that the results might well have been less clear if an unselected series of cases of disease of the mitral valve was studied. Prof. A. C. Lendrum Queen's College, Dundee) described his studies on the histology of the small arteries of the lungs in mitral tenosis. The deposition of fibrin in the vessel walls and the distortion of neighbouring nuclei resemble the changes seen in other diseases affecting different rgans of the body. He attributed these changes in the lungs to a raised pressure in the pulmonary rtery and illustrated them with most pleasing colour photomicrographs.

The discussion of all these papers delivered on the irst day of the symposium did not serve to increase our knowledge of the mechanisms involved in the many and complicated effects discussed by the principal speakers, except, perhaps, the contribution of Dr. G. de J. Lee (St. Thomas's Hospital, London), who stated that appropriate measurements made during a Valsalva manœuvre indicate the existence of vasomotor phenomena in the lungs.

On the second day of the symposium, Dr. G. S. Dawes (Nuffield Institute, Oxford) described his xperiments on the pulmonary function of new-born ambs, and the changes which take place during the irst few hours of life. His observations show the mportance of arterio-venous anastomoses (for xample, patent ductus arteriosus) in the new-born amb, which have the effect of tiding it over the period during which its lungs are becoming more distensible and more fully aerated. He emphasized he need for caution in applying his results to babies as we do not as yet know enough about the details of the circulation in the baby immediately after birth. Prof. W. Melville Arnott (Department of Medicine, Birmingham) described a selection of the numerous tests of lung function now available, and assessed their value as aids to diagnosis. Dr. D. V. Bates (St. Bartholomew's Hospital, London) reported on his xperiments on gas diffusion studies as an aid to the ssessment of lung function. He concluded that mpaired alveolo-capillary diffusion is probably best evealed by a study of the 'diffusing capacity' of nitrous oxide. It is difficult to feel convinced about this, because one would imagine that diffusing capacity and ventilation of the alveoli are in some degree interdependent, and his method of calculating the diffusing capacity certainly does not take into account any ventilatory factor. Dr. L. G. C. E. Pugh London) described the numerous devices (volume-cycled and pressure-cycled) now used for maintaining artificial ventilation for long periods. This communication had much topical interest in view of the present rise in incidence of poliomyelitis. Prof. I. Donald (Department of Midwifery, Glasgow) described a patient-cycled respirator which he has used successfully for assisted respiration in new-born babies. His physiological observations seemed to support some of those described by Dr. Dawes.

The discussion on the papers delivered on the second day of the symposium was noteworthy for two reasons. On one hand, it was clear that workers, conscious of the difficulty of human experimentation, were anxious to discover more about the physiological basis of the various tests of pulmonary function. On the other hand, a noteworthy contribution by Dr. R. Coope (Liverpool) reminded one that, in general, the tests of function which had been discussed had, as yet, only a limited application as aids to diagnosis. The symposium was a success both on the academic and the social sides. Queen's College went to great lengths to make the stay enjoyable, and it is no exaggeration to say that all the members of the symposium returned home refreshed in mind and body.

J. L. D'SILVA

# READING TECHNICAL COLLEGE

H.M. THE QUEEN MOTHER opened the new Technical College of the County Borough of Reading on October 26. This College was first foreshadowed by various Science and Art classes (under the South Kensington regulations); and these classes, which were already being maintained in 1882 by the local authority of Reading, themselves arose on foundations laid earlier by various individuals of vision and vigour. By 1892 a new University Extension College, associated with Christ Church, Oxford, had come into being in Reading and had incorporated the former Science and Art classes.

Eventually, the University College received its charter—to become the University of Reading of to-day—but additional evening classes for local students were continued without break for more than fifty years. Thus, by tradition—and no less by the close co-operation of to-day—important and enduring links have been forged between gown and town. During that same half-century, classes for younger students were also being developed at junior evening institutes by the local authority at Reading.

In 1946 the local authority—having already decided to provide a new technical college, and having acquired a building site—recovered from the University full responsibility for evening courses in engineering, building and commerce; and after a transitional session, the new Technical College organization came into being in September 1947. Its first task was to co-ordinate the existing senior and junior evening classes and to provide for their unified direction in the future. The University continued to provide accommodation (and is still so doing), but demand grew rapidly and the local authority found supplementary accommodation at some thirty additional places—thanks in particular to assistance from industry, schools, the Royal Berkshire Hospital, the public libraries, and various undertakings.

The second objective was the development of a service no longer restricted only to evening-work. Lack of accommodation for day-work was a serious difficulty.

The range of local need was wide. Reading is characterized not by any one predominating industry but by a wide spread of interest. Needs were also urgent, and the authority adopted a bold policy in an endeavour to meet them by compromise, adaptation and by co-operation willingly given on all sides.

Meanwhile, adequate new premises were planned in consultation with the appointed architects, Messrs. Lanchester and Lodge, of London. Work on the site began on October 2, 1950; the foundation stone was laid by the chairman of the Board of Governors (who at that time was also mayor of Reading) on October 3, 1952.

Transfer of the widely dispersed work of the College to the new buildings began at Easter 1955, when the top floor of the main block was handed over, and continued throughout the summer. This operation was completed early in September.

The College is at present organized in six departments: art and printing; building; commerce; domestic and women's trades subjects; engineering; science. During the first three weeks of the present session, 3,400 students enrolled and commenced their year's work: 1,700 for full-time and part-time day courses (most of them also attending additional evening classes) and an equal number for evening courses and classes only. In addition, more than 1,200 have enrolled at four associated evening institutes which are under the direct charge of the principal of the Technical College.

During the interim eight years pending completion of the College buildings, the courses of study provided have been steadily augmented in range and progressively developed in level. Provision is now made for Higher National Certificate and corporate membership students in mechanical, electrical and production engineering, in building and in applied physics. Ordinary National Certificate courses are also provided in chemistry and commerce, and the former are developing towards Higher levels and the associateship of the Royal Institute of Chemistry. There is a wide range of crafts courses—many of them based on requirements for the full technological certificates of the City and Guilds of London Institute.

Courses for apprentices and journeymen in the printing industry have now been introduced and are meeting an important local need.

The Art Department, hitherto handicapped by lack of facilities, is now developing, and its policy is greatly strengthened by the interest of the University School of Fine Art.

The Commerce Department, offering courses leading to the intermediate and final examinations of many professional bodies, is also responsible for courses in modern foreign languages, retail distribution, grocery and further general education.

Domestic and women's trade subjects include various needlecrafts, catering, cookery, nursery nurses' work and pre-nursing. Much of this work is based on examinations; but provision is also made—at both the College and its associated institutes—for the housewife.

All departments also provide many short courses, including a number of postgraduate or refresher type which are arranged from time to time in consultation with industry, trade, commerce and various professional institutions.

The newly completed premises comprise a main block of four stories of total floor area about 100,000 sq. ft., and a workshops block of some 25,000 sq. ft. In order to provide, at this stage, the accommodation essential for the present known demands, emphasis has been placed on workshops, laboratories and drawing offices rather than on classrooms. There is no central hall or gymnasium; but a refectory, staff and students' common rooms, departmental libraries and staff studies have been included. There is also one large main lecture theatre. A master plan h been prepared by the architects for future develo ment. The internal arrangements of the new buildin have been carefully planned in respect of both shor term and probable long-term requirements; the have been made as flexible as possible so that chang in the use of rooms and services can be made t simply and economically as possible. Invisible ceilin panel heating is provided, allowing uninterrupte wall space. Filament lighting is used generall except for drawing offices and certain rooms in th Art and Printing Department, where fluorescen lighting is preferred.

In general planning, regard has been paid not onl to the specific needs of each department but als to encourage the closest possible liaison betwee them, in the strong belief that all contribute thei special elements within the total pattern of lif to-day and also that each has much of lastin cultural value to share.

A plinth is provided in the main College forecour for the display of pieces of sculpture, to be replace every three years on the basis of a special com petition arranged in co-operation with the University

---

# NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

THE annual report of the National Institute fo Research in Dairying is a tribute to the remark able variety of work which is being done to improv dairy products. Established in 1912 at the Universit of Reading, the Institute now has eight researc departments. Three of these—the Departments o Dairy Husbandry, Feeding and Metabolism, an Physiology—deal, for the most part, with the prob lems, both immediate and fundamental, associate with the technique and scientific background of mil production. Included in the scope of these thre Departments are questions of dairy farm manage ment, the growing of crops suitable for feeding dair cattle, the nutrition of dairy stock, and control o reproduction and lactation in cattle.

The other five departments—Bacteriology, Chem istry, Physics, Engineering and Nutrition—deal wit the application of science both to farm productio and to the more strictly industrial side of practica dairying. Problems, both *ad hoc* and basic, associate with distribution and manufacture of milk, and wit the quality of milk products, are dealt with in thes Departments, and they are inevitably concerne from time to time with investigations directly affecting the consumer of milk and of other dairy products

Besides these eight Departments, there are Section concerned with isotopes, statistics and psychology as well as an experimental dairy.

Many investigations were begun or continue during the year. Further work on the rate of mil and milk-fat secretion, for example, has confirme that the former decreases with increasing interva since the last milking more rapidly than the latter the positive correlation between the milking-rat of an individual animal and the total lactation yiel has been confirmed. It was also shown that th greatest number of new udder infections occurs i the first month of lactation, and in quarters whic have not previously been infected the new infection rate is found to be approximately 3 per cent in th rst month and 1 per cent for subsequent months ; nce a quarter has been infected and freed from fection, the probability of re-infection increases ith the number of previous infections.

An examination of copper as a growth promoter n pigs indicated that either pure copper sulphate or mineral mixture providing copper sulphate at about ·1 per cent of the weight of the fattening meal gives n increased rate of growth in fattening pigs ; even t this high level there is no suggestion that copper s toxic to fattening pigs. No benefit was obtained ither in live-weight gain or efficiency of food utilization when the floors of styes were kept artificially warmed in winter.

Another inquiry revealed that, when measured in erms of the milk production of grazing cows, meadow fescue has consistently outyielded, in each of two seasons, both perennial ryegrass and cocksfoot. An nvestigation into the production of saliva by the ow showed that a milking cow, on a normal diet, in the course of a day probably produces more than ten gallons of saliva, a large proportion of which appears to be secreted while she is eating.

There are indications that the oestrogenic isoflavone, biochanin A, recently isolated from red clover, is present in other clovers, and also, probably to a lesser extent than in red clover, in timothy, Italian ryegrass, meadow fescue and cocksfoot. This substance is present (along with the related oestrogen genistein) in subterranean clover. It is, however, doubtful whether, in current agricultural practice in Britain, oestrogens in pasture plants have any significant effect on milk production or other physiological activities of livestock.

Claims made abroad that the addition of menadione to raw milk, or to the food of lactating cows, caused a marked improvement in keeping quality of milk could not be substantiated. In certain circumstances, menadione in the milk appeared to have a deleterious effect in cheesemaking. Its use as an additive to milk, in any event illegal, is also undesirable on technological grounds.

It was found that the gut contents of chicks about to hatch are sterile ; but those kept without food after hatching develop a flora in a few hours. When recently hatched chicks are fed, a balanced gut flora is established within two days.

The whitening of milk which occurs at temperatures above 60° C. increases in magnitude with the acidity of the milk, and increases with additions of soluble proteins. On heating milk further, the rate of browning seems to depend only on the *p*H, the rate increasing with alkalinity. Milk sterilized in a plate heat-exchanger at 135° C. is whitened in colour and not browned.

The young calf was shown to be a poor converter of carotene to vitamin A. This seems to be the case for all very young animals examined, namely, calves, rats and chicks. Conversion efficiency increases with age.

A significant improvement in growth-rate and a reduction in the incidence and severity of scouring were frequently brought about in young calves by giving them an antibiotic supplement to the diet. The effect, however, appears to be much smaller where the calves are born and reared under good conditions of health and management.

An interesting finding was that the sense of smell seems to be less sensitive than the sense of taste in discriminating between flavours in dairy products, even when the observers concerned think otherwise.

# SICKLE CELL GENE DISTRIBUTION

DR. H. LEHMANN has recently published two papers. The first is about the distribution of the sickle cell gene (*Eug. Rev.*, 46, 3 ; 1954) ; the second deals with the Andaman Islands (*St. Bartholomew's Hospital J.*, 59, 99 ; 1955). From the observation of Herrick in 1910 of a case of chronic anæmia in a Negro student characterized by 'sickle'-shaped red blood cells, investigations have continually proceeded. It was first shown by Huck in 1923 that sickle cell anæmia behaved as a simple Mendelian character and that heterozygotes or carriers could be identified by the anaerobic incubation of blood, whereupon fresh normal blood would take on the sickle appearance. The chemical aspect was studied by Pauling (1950), who found that sickle cells contain a hæmaglobin which differs in its physical properties from normal adult hæmaglobin. Normal and sickle hæmaglobins could be separated by electrophoresis.

The incidence of the 'sicklæmic' gene was high in American Negroes (about 10 per cent) ; but other races did not seem to possess it.

In 1944 and 1945 Evans initiated a large-scale survey on the frequency of occurrence of sicklæmia in West Africa, and found a 20 per cent incidence in 561 Africans from Nigeria, the Cameroons, Gambia and the Gold Coast.

Further large-scale observations were made in West Africa by Findley and his collaborators, the results showing a frequency not very different from those found by Evans. Sickle cells were reported from East Africa in 1945 by H. C. Trowell and from Northern Rhodesia (12 per cent) in 1946 by Beet. Altmann in 1945 reported their absence in South African Negroes.

In 1949 Lehmann and Milne examined nearly 5,000 individuals of twenty-four different tribes in Uganda. In the Nilotic tribes the incidence of sicklæmia was strikingly homogeneous and varied from 21 to 28 per cent.

Foy and his colleagues (1954) surveyed the southern Sudanese and found that the Nilotics fall into two groups, one allied to the Uganda Nilotics and the other with Half Hamitic affinities.

The former group had a high sicklæmia incidence and the latter usually a low one (0·8–3·9 per cent).

In Bantu-speaking tribes sicklæmia varied in incidence, from 2 per cent in the Bairu tribe to 45 per cent in the Baamba—a secluded pigmoid tribe in the forest of the Mountains of the Moon.

The distribution of the sickle gene in Uganda seems to be connected with the invasion route of the pastoral Half Hamites, being lowest among the Bantu along that route and highest in the less-accessible swamps, jungles and mountain tops.

Allison (1954) put forward another explanation of the variable incidence of the sickling gene in the Bantu. It is assumed that the invaders occupied the healthiest and least malarious zones of the country. It is further assumed that the sickling gene has a selective advantage in malarious tracts, the *S* hæmaglobin being less desirable to the malaria parasite than the normal *A* hæmaglobin. It follows that the sickling gene will be most frequent in malarious surroundings. This theory is supported by the fact that the Half Hamitic tribes all live in the least malarious areas of Uganda and that adjacent Bantu tribes share both low malaria incidence and low sickling. But as Herman points out, the question is complicated by the fact that a large admixture of physical Hamitic features in a Bantu tribe—presumably through intercrossing—is also connected with low sickling.

These researches led to the possibility that the distribution of the sickling and other blood genes (Rhesus, *ABO*, *MNS*, etc.) could as genetical markers throw light on to Haddon's theory of a Neolithic immigration from India into Africa.

Accordingly, in 1952 the Nuffield Foundation financed an expedition to South India, and extensive observations of the incidence of sickling were made by Dr. Lehmann in a number of communities.

The gene was found among the Veddoids, of the Nilgiris—primitive peoples who until recently were food gatherers with no knowledge of agriculture. The incidence in both Pancyans and Irulas was very high—more than 30 per cent—while in the Tamils, Telegus and Canarese the gene was not found.

Further reference is made to the prevalence of the sickling gene in the Veddoids of Arabia, and also in Greece, and to the distribution of other blood genes in relation to migratory movements of populations in past times.

Dr. Lehmann, in a brief summary, assigns high incidence of the sickling gene to three major factors: (1) the anthropological derivation of the population; (2) genetic regulation such as a high mutation-rate or balanced polymorphism (Neel, 1953); (3) a social situation which produces inbreeding.

The discussion is not on the whole well balanced, and no reference is made to a possible high coexistence between malaria and sickling in either South India, Arabia or Greece, though data are probably available. The fact that the highest sickling-rates are found in the socially lowest stratum of a population seems to be significant only in relation to gene introgression from other communities.

The second paper contains a general account of the Andaman Islanders. The results of the blood groupings did not point to any connexion between the Andamanese and the African peoples, but rather indicated relationship with the inhabitants of the Admiralty Islands and New Guinea. S. C. HARLAND

# NATURAL INSECTICIDES IN WEST AFRICA

A SURVEY of the natural insecticides used by the peoples of West Africa has been made by Dr. F. R. Irvine (*Col. Plant and Animal Prod.*, 5, No. 1).

The question of the toxicity to man of preparations used as insecticides is important where food crops are concerned; many of these African insecticides are also used for catching fish. The action of some of them is merely to stupefy the fish which, when afterwards eaten, are quite innocuous.

West African insecticides fall naturally into three groups, those containing (1) alkaloids; (2) rotenone or its close relatives; and (3) resins and oils. A few others are useful on account of an acid, tannin, or latex.

Of those containing alkaloids, the tobacco plants, *Nicotiana tabacum* and *N. rustica*, both probably long known as insecticides to West Africans, are in common commercial use. Species of *Datura*, especially *D. metel*, the active principle of which is hyoscine or scopolamine, are used on floors to destroy a bad pest—the jiggers or sand fleas which bore into th feet.

The powdered seeds of certain *Annona* have bee reported from the tropics both as insecticides and a fish poisons. Water suspensions of the seeds c *A. reticulata* produced a high percentage of kill amon the green bugs, *Lecanium*.

Another and more powerful alkaloid is found i the bark of the sassy bark or red water tre *Erythrophloeum guineense*, which is used for destroying fish, game animals and rats, and as ingredient i arrow poison. The active compound is erythrophleine which resembles digitalis in its action on the huma body. In West Africa insecticidal use is made of th leaves, which are put with stored corn to keep insect away.

A leguminous shrub, *Sophora tomentosa*, contain in its seeds about 2·0 per cent of cytisine. Thi alkaloid has proved to be a relatively potent insecticid to adult *Aphis rumicis*, resembling nicotine in it physiological action.

The leaves of the Indian nim tree, *Melia azedarach*, have been successfully used on the Gold Coast for preventing infestation of cocoa beans by the insect *Ephestia*. Elsewhere they have been found to be repellent to locusts, and it is claimed that extracts can be effectively applied for the protection of fruit, vegetable and cereal crops.

Many plants contain rotenone or allied compounds. About two dozen species of *Tephrosia* are used as fish poisons in various parts of the world and some of them are used as insecticides. Among these, *T. vogelii* is of particular interest. Its pounded leaves and pods, thrown on water, stupefy fish in such numbers that its use had to be prohibited in certain areas. The fish so caught are quite edible. The seeds, too, have been proved by Wilbaux to be toxic to molluscs. (Here may be a substitute, probably innocuous to pets and song birds, for the material used in poison bait to combat the ubiquitous slug in British home gardens.) The leaves, when dried, are widely used by Africans for destroying human insect and other parasites, for example, head-lice and fleas. They are used by Europeans in Nyasaland against dog ticks and fleas and in Rhodesia and elsewhere against lice. *Tephrosia*, in at least five species, contains rotenone and other compounds in common with *Derris* and *Lonchocarpus*.

Another well-known fish poison is the leguminous shrub, *Mundulea sericea*, which kills rather than stupefies; it is risky to eat the fish afterwards. In Mysore, India, the pulverized bark of *M. sericea* has been used against various pests and the bark, roots and seeds as fish poison. East Africans declare the pounded bark to be sufficiently potent to kill man, and put into the water, they say, it drives away crocodiles. Though only small quantities of rotenone have been found in the air-dried bark, its toxicity is thought to be due to the presence of allied compounds. Certain East African tests showed it to be almost as lethal as *Derris* roots.

Allied to *Derris* is the leguminous genus *Lonchocarpus*. In South America this produces the well-known insecticide, cube, which, like derris, is a piscicide.

Some of the preparations which contain resins or oils are toxic by contact methods while others are effective as fumigants.

Certain *Dichapetalum* species are poisonous: their seeds to man, rats and parasites, their leaves to ook. Their poisons are believed to be due to resins nong other extractive matter. Particularly potent *D. toxicarium*, though paradoxically enough its uit pulp and that of certain other *Dichapetalum* ecies is edible. Its seeds are sold as rat poison in reetown, Sierra Leone.

Obnoxious to insects is the bright yellow and partly ater-soluble gum exuding from the cashew (*Ana- rdium occidentale*), and this adds to its value in book- inding. The oil from the nutshells was proved in 938 to be destructive to mosquito larvæ, and has een demonstrated to have distinctly toxic effects n certain grain weevils and moth larvæ.

Among fatty oils are the thick greenish oil from e seeds of the herb, *Gynandropsis pentaphylla*, used gainst human parasites (hair-lice) and as a piscicide, e bitter purgative oil from the seeds, and probably tex of the Mexican poppy, *Argemone mexicana*, hich is used by certain pagan Nigerian tribes for arding off termite attack.

Conspicuous among aromatic insecticides are e essential oils of the Labiatæ. Of these the rongly scented *Hyptis spicigera*, *Leucas martini- nsis* and *Ocimum americanum* are burned in rooms get rid of mosquitoes, and layers of the *Hyptis* re placed below bundles of millet to keep away ermites.

Although African growers have available a variety f materials of insecticidal value, Dr. Irvine does not uggest that these materials are necessarily alterna- ives to modern synthetic insecticides. In making choice, many factors, such as local availability, ersistence, ease of application and cost-effectiveness atio, need to be taken into account. These plant roducts should be considered as useful supplements n the struggle against tropical pests. There is much cope for interesting research into the action of these egetable pesticides, either alone or in combination, s well as into the chemistry of their active principles.

---

# D. I. MENDELEIEFF AND THE PERIODIC SYSTEM

DMITRY IVANOVICH MENDELEIEFF (1834–1907), the discoverer of the periodic system of he elements and one of the greatest chemists of odern time, was also a very great Russian, and it inevitable that in the U.S.S.R. much time and nergy have been devoted to his life and work and o establishing his place in the history of science.

Mendeleieff was closely connected with education, esearch in pure and applied chemistry, mining and conomic development of Russia. He was also one f the founders in 1868 of the Russian Chemical ociety. The first Mendeleieff Congress met in ecember 1907, the year of his death. In its scope nd purpose this congress was similar to a meeting f the British Association. Subsequent Mendeleieff ongresses took place in 1911, 1922, 1925, 1928, 1932 nd 1934. The last of these in 1934 was the jubilee ongress in celebration of the centenary of Mende- ieff's birth. For this congress the Academy of ciences published "Selected Works of D. I. Mende- ieff"; but in 1937 it began publishing the complete orks in fourteen volumes, of which a number has lready appeared. Recent literature on Mendeleieff nd on the periodic system in the U.S.S.R. is very xtensive. Six books dealing with Mendeleieff and he periodic system reviewed here are of a particular interest to scientists and historians of science. One of these books is published in English, the remaining in Russian.

The first three are concerned with the life and work of Mendeleieff and the last three with the periodic system of the elements. The book written by Prof. B. G. Kuznetzov[1] is a first-class account of the life and work of M. V. Lomonosov (1711–65), N. I. Lobachevsky (1793–1856) and D. I. Mendeleieff (1834–1907). A more popular account is given by Pisarzhevsky, somewhat lengthy in the Russian text[2] and condensed in the English text[3]. The English edition is a nicely bound volume containing numerous well-produced illustrations, available at a very reasonable price.

Mendeleieff's greatest contribution to science, the periodic system, and its derivatives, has, since its discovery in 1869, played a very important part in the development of chemistry and physics. In 1944 the Russian All-Union Chemical Society, in conjunction with the Chemical Section of the Academy of Sciences, celebrated the seventy-fifth anniversary of the discovery of the Periodic Law (1869) and of the foundation of the Russian Chemical Society (1868). The papers read at these meetings were published as a volume in 1947[4]. The first part of this book (pp. 11–114) is devoted to the periodic law and contains five articles: (*a*) the periodic law of D. I. Mendeleieff and its creator, by the late A. A. Baikov; (*b*) the periodic system as the foundation of modern chemistry, by S. A. Shchukarev; (*c*) the periodic law of Mendeleieff and its significance in natural history, by the late A. E. Fersman; (*d*) the transformation of the elements and the periodic law, by V. G. Khlopin; and (*e*) the physical meaning of the periodic system, by A. F. Yoffe. The second part (pp. 115–265) is by V. V. Kozlov and A. I. Lazarev and deals with the history of the Russian Chemical Society. It includes biographical sketches of Russian chemists and contains numerous portraits and other illustrations. Unfortunately, it is not provided with an index.

A most spectacular achievement of the past decade has been the systematic study and classification of Mendeleieff's archives. A large number of 'scraps of paper' containing rough notes or simply scribbles, rough manuscripts of articles, printed copies with the author's correction and amplification notes, rough copies of letters and other materials—all this, when arranged and interpreted, provides a very valuable contribution to the history of the creation of the periodic system. The task of classifying and interpreting this material has been accomplished by Mendeleieff's daughter, the late M. D. Mendeleieff, T. S. Kudryavtzeva and B. M. Kedrov.

The first book dealing with this material was published in 1950[5]. In it only three documents are given and discussed: (1) the manuscript of the earliest form of the periodic table, scribbled over and altered; (2) the manuscript of the second form of the periodic table, the one which was sent to the printers in February 1869 and published in Russian and in French (March 1, 1869); (3) the original Russian text of Mendeleieff's article (dated July 1871), later translated into German and published in the *Annalen der Chemie und Pharmacie* (Supp. Vol. 8, pp. 133–229; 1872). The reproduction of these items is followed by a detailed account by B. M. Kedrov.

Plans have been made for the complete publication of the newly discovered material in three volumes: Vol. 1, covering the period 1869–71[6]; Vol. 2, period 1860–68; Vol. 3, period 1872–1906. Of these, only Vol. 1 has so far appeared. It was published in 1953 and is a very substantial book of 866 pages, full of photo-reproductions of the original documents, explanatory tables and notes. It contains the three documents published in the previous book[4], but more fully annotated and analysed, and a mass of other documents—various sketches of the periodic table (including rough sketches of the spiral form), notes on various topics connected with the periodic system, manuscripts of articles, amended articles, letters, programmes of lectures, and so on. All these documents and their interpretation and annotation are valuable material for the historians of science.

A short review of this kind does not allow of detailed discussion; but the main process of Mendeleieff's creative activity with regard to the discovery of the periodic system may be summarized as follows. After lecturing on organic chemistry and chemical technology at the University of St. Petersburg from 1861, Mendeleieff at the age of thirty-three was appointed to the chair of inorganic or general chemistry in 1867. The preparation of this new course of lectures led him to write his text-book, "The Principles of Chemistry". He knew about some attempts at classification of the elements; but he had not seen the works of A. E. Béguyer de Chancourtois and J. A. R. Newlands. "When I began to write my text-book," Mendeleieff told Braunor, "I felt that I needed a system which would allow me to classify chemical elements. I had discovered that all existing systems were artificial and therefore useless for my purpose. I was anxious to establish a natural system. With this purpose in mind I wrote the signs of the elements on little slips of cardboard together with their atomic weights, and after this I began grouping them in different ways according to their similarities, but this did not satisfy me, until finally I placed the cards one after the other in order of the increasing weights of the element. Having placed in the table the first row: H = 1, Li = 7, Be = 11, C = N = 14, O = 16, F = 19, I discovered that t following elements form a second row below t first row, beginning with lithium. Further I fou that in this new row—Na = 23, Mg = 24, Al = Si = 28, P = 31, S = 32, Cl = 35·5—sodium repe every property of lithium, and the same applies all other elements. Similar repetition occurs in t third row, after a certain period, and continues in rows" (5, p. 141). This may be a simplified accou of his approach to the problem, because the 'scra of paper' show a much more elaborate scheme arrangements and groupings of the elements. It interesting to note that the first two sketches of t periodic table were variants of the 'long chart', wi vertical columns corresponding to periods, whi later, struggling with the presence of two sets similar elements in the long periods, Mendelei deliberately telescoped the 'long chart' into the 'sho chart'. Subsequent history of the periodic table h shown, however, that the 'long chart' is in a bett agreement with the modern view of atom structure and is more suitable for certain branch of science.

# APPARENT TRANSFORMATION OF COLLAGEN FIBRILS INTO 'ELASTIN'

By PROF. D. BURTON, DR. D. A. HALL, DR M. K. KEECH, DR. R. REED, MISS H. SAXL,
PROF. R. E. TUNBRIDGE, O.B.E., and MISS M. J. WOOD
University of Leeds

THE present communication deals with certain electron microscopical, histological and biochemical observations which appear to indicate a possible transformation of collagen fibrils into elastin-like material. This work forms part of a general study of the properties of connective tissue undertaken in the University of Leeds by the Nuffield Gerontological Unit (Dr. D. A. Hall, Miss H. Saxl) and the Departments of Medicine (Dr. M. K. Keech, Prof. R. E. Tunbridge) and Leather Industries (Prof. D. Burton, Dr. R. Reed, Miss M. J. Wood).

On the basis of electron-microscope[1] and biochemical studies[2], it has been suggested that the material common to all forms of elastic tissue is a complex system, consisting of two types of long-chain molecules, one a mucoprotein, the other a polypeptide chain, coated by a dense cement material—the so-called elastomucin. Morphologically, under the electron microscope, elastin-like fibrils are uniformly dense, ill-defined in shape, with no specifi structural feature, in contradistinction to the fibril of collagen, which have characteristic cross-striation (Fig. 1).

## Electron-Microscope Studies

As a source of collagen fibrils for possible con version to elastin, use has been made of preparation obtained by the modification of Neuman's method described by Keech[3]. These preparations have bee obtained from abdominal skin of patients of variou ages, ranging from nine to eighty-two years. Althoug Neuman[4] claims that this material is the purest an least degraded form of collagen available, there is n evidence that the extraction procedure does no affect the intra-fibrillar constituents, especially poly saccharide. However, it would appear that th ground substance has been removed, and any effect observed arise from the collagen fibrils themselves and not from any extraneous source. For com

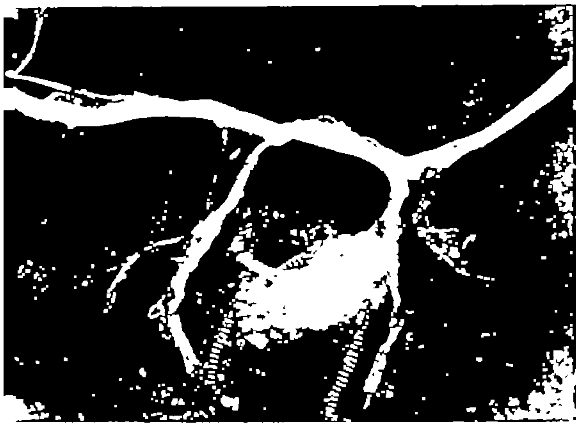

Fig. 1

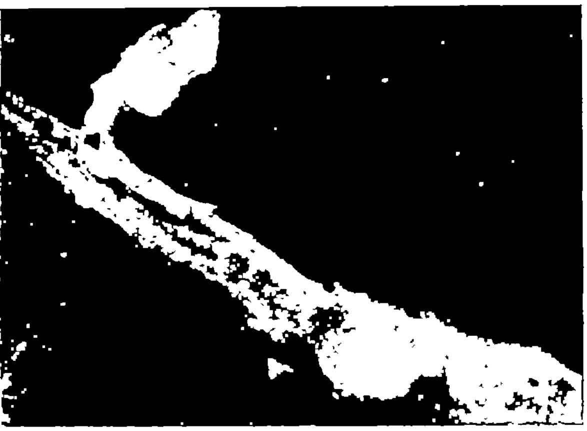

Fig. 2

Fig. 1. Control material from fresh whole dermis (7-year old child) showing striated collagen fibrils and an elastin-like fibre.
Fig. 2. Prepared dermal collagen, from a child aged 9 years, following incubation with borate buffer ($p$H 8·8) for 24 hr. at 37° C. Apparent transformation of bundle of collagen fibrils into 'elastin'

arison, fresh samples of skin were also examined. ll preparations contained a small quantity of enicillin and streptomycin mixture, which successully prevented bacterial contamination.

As part of a general survey of the effects of various eagents, for example, acids, alkalis and enzymes, on ollagen, the substrates were treated with borate uffer solutions ($p$H 7–10·4) at 37° C. for varying eriods of time. The electron microscope revealed a arked increase in amorphous material associated ith degenerate collagen fibrils, and, by comparison ith the controls, an increase in structures closely esembling the fibres of elastic tissue (Fig. 2). Moreover, the longer the time of treatment, the greater he number of such structures. In addition, collagen brils in various stages of modification were observed, anging from the typical banded appearance to fragents of irregular shape, some showing a filamentous tructure. This variety of structures indicated that ertain collagen fibrils had degenerated, with the roduction of large quantities of amorphous material; he latter then apparently coated the many types of brils present, cementing them together and rendering he cross-striations and fibril outline indistinct. A rther finding in collagen treated with alkali was the resence of a large number of dense, fine threads, bout 150–250 A. in diameter and ranging in length from 2000 A. to about 4000 A. Their form varied, being either rod-like or curved with slightly tapered ends, both types occurring together (Fig. 3). These fine threads were randomly distributed on and between the collagen fibrils and were observed in all experiments in the range of $p$H values from 7 to 10·4, but only in the early stages of the treatment. At $p$H 9·8 and 10·4 the threads were longer and slightly thicker than those recorded at lower values, but after 2 hr. treatment at 37° C. they were no longer seen.

As the age of the sample increased, the effects observed, although still apparent, became more difficult to assess in view of the fact that the controls contained larger proportions of elastin-like structures.

Similar morphological appearance, that is, fibres resembling elastin in all stages of formation, were observed following the treatment of collagen with 1 per cent sodium metaperiodate in phthalate buffer of $p$H 5·0 at 37° C. for times ranging from 1 to 6 hr. (Fig. 4). It may be significant, however, that at this $p$H no threadlike structures were produced. Incubation with trypsin and chymotrypsin (each obtained from pig and ox) in phosphate buffer of $p$H value 7·3 at 37° C. for times ranging from 3 to 24 hr. also produced elastin-like structures.

Transformation into elastin-like structures was also observed, although the changes in the adult tissue

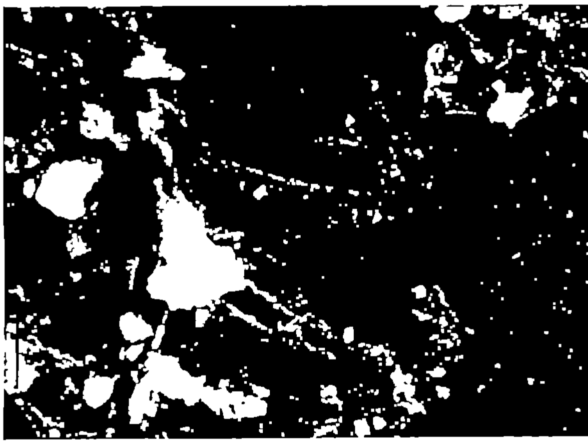

Fig. 3

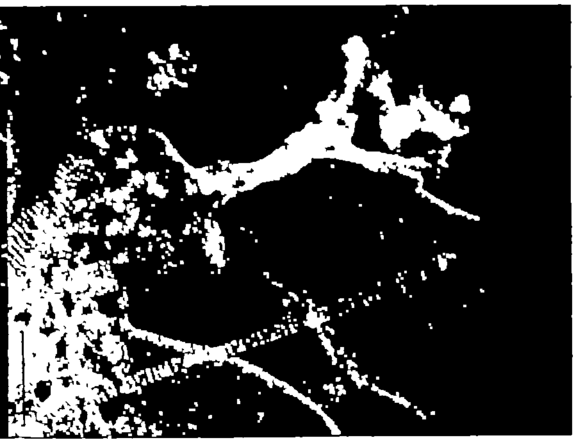

Fig. 4

Fig. 3. Same substrate and conditions as Fig. 2. Incubation time 14 hr., showing collagen, amorphous material and fine thread-like structures randomly distributed throughout the field. Fig. 4. Same substrate as Fig. 2 treated with 1 per cent sodium metaperiodate in buffer ($p$H 5·0) for 1½ hr. at 37° C. The degenerate collagen appears to be changed into 'elastin'

were less marked when fresh whole dermis was treated in borate buffer, pH 8·8 at 37° C.

It appears, therefore, that alkalis and certain pancreatic enzymes in alkaline solution, by acting on collagen at 37° C., may bring about profound changes. In the early stages of the reaction, small, threadlike structures are produced. Later, these can no longer be observed and many of the collagen fibrils appear to disintegrate with the formation of much amorphous material. Thus, there are strong morphological grounds for believing that collagen fibrils, under certain conditions—particularly those which are known to affect mucopolysaccharides—are capable of being transformed into structures closely resembling elastin tissue fibres. It is clear, however, from the electron micrographs, that the conversion of collagen into material resembling elastic tissue is not complete, that is, some collagen fibrils retain their characteristic cross-striated appearance.

## Biochemical Studies

Morphological similarity alone, however, is no proof of strict identity and hence, parallel with the electron microscope work, biochemical studies were also made. Previous work on the amino-acid analyses of collagen and of chemically treated elastic tissue, which from the point of view of the electron microscope was apparently devoid of collagen fibrils, indicated marked differences in the relative amounts of certain amino-acids[5], a fact which in the past had caused us repeatedly to reject the possibility that elastin could be derived from collagen. Hydroxyproline constitutes 10 per cent of the amino-acid residues in collagen, but only 1·6 per cent of those in elastin. Hence the complete conversion of collagen into elastin should involve the removal of about 100 moles hydroxyproline for each $10^5$ gm. of collagen. At the same time, other amino-acids which are also of low concentration in elastin would be expected to be lost.

In the initial stages of this work, since it was impracticable to examine the changes in all amino-acids, hydroxyproline was chosen for immediate study. Collagen preparations were obtained by methods identical to those used in the electron-microscope work; in addition, the treatment with alkaline buffer solutions was taken as the least complicated procedure for which biochemical confirmation of the structural findings might be obtained. After treatment with alkaline buffer, the reaction mixture was centrifuged and the residue separated from the supernatant liquid. The protein content of the supernatant was determined by the method of Lowry *et al.*[6]. Appropriate aliquots of the supernatant were hydrolysed under reflux with 6 *N* hydrochloric acid for 24 hr. and the hydroxyproline determined by Martin and Axelrod's[7] modification of the Neuman and Logan reaction[8]. The reducing sugars in this hydrolysate were estimated by the prussian blue method[9].

In certain cases the residues were re-extracted with further buffer, while in others replicate samples were incubated for varying periods.

Two samples from young subjects (7 and 3 years) were examined after 24 hr. extraction and the hydroxyproline content of the extracted protein found to be 33 and 24 per cent, respectively. After a further 40 hr. extraction, the percentage hydroxyproline in the protein from the latter sample was 18 per cent. Examination of a 15-year old subject demonstrated further the dependence of the hydroxyproline level on the time of extraction (Table 1).

Table 1

| Time of extraction with buffer (hr.) | Protein extracted (per cent of dry weight) | Hydroxyproline content of extracte protein (per cent) |
|---|---|---|
| 12 | 1·30 | 12·9 |
| 20 | 1·66 | 13·1 |
| 41 | 1·85 | 18·3 |
| 65 | 2·25 | 10·8 |
| 118 | 2·60 | 9·7 |

It would appear, therefore, that either the concentration of hydroxyproline of the extracted prote varies, or, more likely, a number of protein fractio are extracted simultaneously, and the varyi hydroxyproline content of the whole is merely function of their varying rate of extraction.

The degradation of the collagen accompanied by variable retention of either hydroxyproline-rich hydroxyproline-poor polypeptides has been borne o by further studies. In a number of other sampl examined, the hydroxyproline content of the extra was very low indeed, remaining less than 6 per cen for the first 24 hr. extraction over an age-range fro 5 months to 61 years, although the amount of prote extracted dropped progressively with age. The san variability was also observed in estimations of th liberated polysaccharide, for on those occasions whe protein with high hydroxyproline content wa extracted during the first 24 hr. the polysacchari content was proportionally high.

Preliminary experiments with fresh tissue throug which buffer was forced under pressure, followed b the fractional collection of the eluate, have produce results completely in conformity with the abov observations. By this procedure, it has been possib to separate a protein fraction rich in hydroxyprolin in a limited volume of eluate. The average hydrox proline content of this material is 40 per cent, an although insufficient material has as yet bee obtained for a complete analysis, it is noteworth that arginine, another of the amino-acids which is a markedly different concentration in collagen an elastin, is also present in the extracted protein i very high concentration.

## Histological Studies

Samples of the skin tissue which had been extracte with alkaline buffer under pressure as above wer examined histologically. Both frozen sections an teased preparations fixed in formol-saline wer examined after staining with Hart's modification o Weigert's stain by normal and by polarized light.

Lamellar structures were observed in both th control and the treated material, but were mor numerous and exhibited a wider variety of stainin properties in the latter. Some of the lamellæ in th treated material were unstained, refractile and highl anisotropic and associated with dark blue-black masse of amorphous material. Other lamellæ in the treate material stained pale blue or pink and were anisotropic whereas others stained like elastin and were no anisotropic. Further structures, histologically indis tinguishable from elastin, in the form of wavy intensely blue-black fibrils were observed. Highl anisotropic lamellar structures of this type have bee described by A. J. Cruise (personal communication in skins of various animals and in human achille tendon. He also reported that they can be split u into fine fibrils by crushing. Occasionally non staining anisotropic lamellar structures have bee observed so arranged that it might be inferred tha hey have been formed as a result of the fusion of collagen fibrils. Since such a wide range of staining properties and degrees of anisotropy exist, it is ossible that this gradation reflects the production f material staining like elastin from collagen. Whether such is the case or not, the fact remains that material staining like elastin is produced from collagen under conditions known to be associated with comparable biochemical changes.

## Discussion

It appears, therefore, that under conditions which lead to the transformation of collagen fibrils into structures closely resembling those found in naturally occurring elastic tissue, protein fractions rich in hydroxyproline and arginine are liberated from the collagen. Such changes in the distribution of amino-acids in the system are those to be expected from a comparison of the chemical composition of both collagen and elastin, and by themselves support the view that the transformation product is indeed elastic tissue. It is clear, however, that if elastin is derived from collagen fibrils, the transformation must involve a deep-seated and complex breakdown of some of the polypeptide chains of collagen, particularly since protein fragments low in hydroxyproline and arginine content are released simultaneously.

This generalized breakdown of collagen followed by recombination of certain of the products to form 'elastin' is consistent with the existence of 'elastins' of varying composition, since the degree of degradation, and the composition of the resultant amorphous elastomucin, can presumably vary over quite wide limits without affecting the ill-defined morphology of the elastin fibre. This possibly explains the varying composition of 'young light' and 'old heavy' elastins (Lansing)[10], and probably accounts for the observation that a third component, apparently intermediate in properties between elastin and collagen, exists in aorta tissue. From its amino-acid content, Hall has suggested that this component resembles collagen[5]. The possibility that collagen fibrils actually form an integral part of certain natural elastins has been suggested by Banga[11], and certain of our preliminary observations support this view.

Elastin supposedly freed from collagen by prior treatment with acetic acid[9] was examined under the electron microscope and found devoid of visible collagen. Following incubation with collagenase at 37° C., the presence of collagen-like fibrils was revealed which were ultimately completely digested by the enzyme.

It would appear from the fact that the transformations occur equally in the case of collagen completely freed from ground substance, that is, prepared by the modification of Neuman's method described by Keech[3], and in fresh tissue, that the transformation is essentially a property of the collagen fibrils themselves and is not dependent on the presence of ground substance or matrix. This does not preclude the participation of the ground substance in any *in vivo* process.

As might be expected, since the transformation conditions are those which are likely to affect the mucoprotein links in collagen, the release of protein fractions rich in hydroxyproline is invariably accompanied by the release of carbohydrate material with a high content of reducing sugars. This not only confirms the importance of polysaccharides in helping to determine the stability of collagen fibrils, but also points to a possible close association of hydroxyproline and polysaccharide in collagen. In any event, the present studies indicate that hydroxyproline residues may also be of particular importance in aiding the cohesion of collagen fibrils, in agreement with the recent work of Gustavson[12], who has shown that the hydroxyproline content of various forms of collagen is an index to their thermal stability.

In 1894, Unna[13] suggested that there exists a family of connective tissue components with differing tinctorial characteristics showing a full spectrum of properties between collagen and elastin. These substances, which were observed in pathological tissue, he named collacin, collastin and elacin, and claimed they were degradation products of collagen on one hand and elastin on the other. There has been much doubt as to the identity of these materials, especially after chemical analyses of so-called typical examples of collagen and elastin had shown how markedly these two differed in amino-acid composition[14]. However, no one has as yet been able to describe any cell to which definite elastoblastic activity could be ascribed, and recently the morphogenetical dependence of elastin on collagen has been emphasized. For example, Robb-Smith[15] says: "In the embryo and in healing wounds elastica appears later than the collagen fibrils, and indeed it would appear that collagen is a prerequisite for its formation".

If some process similar to that induced artificially by alkali described above is operative *in vivo*, many of the anomalous observations of embryology, pathology and histology could be explained. If collagen can be transformed into elastin, there is no need to postulate a separate elastoblast. The presence of elastin in smaller or greater amounts in most sites containing collagen is explained, and degenerate diseased tissues which contain histologically elastin-like structures assume their proper position in the scheme of connective tissue components, since it has been shown that the elastin-like masses in senile elastosis are really degenerated collagen with excess of amorphous material[16].

On the basis of X-ray diffraction studies, Astbury has tentatively placed elastin in the collagen group of fibrous proteins[17]. These observations appear to support this contention.

Full details of the apparent transformation of collagen fibrils will be reported later.

The pancreatic fractions and collagenase (*Cl. welchii*) were kindly supplied by Dr. C. G. Pope, of the Wellcome Research Laboratory, and the collagenase (*Cl. histolyticum*) by Dr. J. D. MacLennon.

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Isocitritase in *Escherichia coli*

Isocitritase, the enzyme which splits isocitric acid to succinate and glyoxylate, has been found in *Pseudomonas aeruginosa*[1,2] and *Penicillium chrysogenum*[3]. This communication describes this enzyme in *Escherichia coli*.

*E. coli* cells (strain *B26*) were grown for 24 hr. with aeration on a medium consisting of 1·5 per cent sodium acetate, 0·8 per cent potassium phosphate, 0·4 per cent ammonium sulphate, 10 per cent (by volume) tap water for inorganic ions and 0·1 per cent yeast extract at *p*H of 7·0. Initial experiments with extracts of these cells treated twice with 'Dowex-1' showed that citrate is metabolized to equivalent concentrations of succinate and glyoxylate without the production of carbon dioxide (Table 1). The same extracts, when fractionated to remove aconitase after the procedure of Smith and Gunsalus[1], were found no longer to produce these compounds from citrate or *cis*-aconitate but were active on isocitrate. The stoichiometry of the isocitritase reaction is shown in Table 2. Partially purified preparations required a divalent ion as well as cysteine. Isocitritase does not require coenzyme A or adenosine triphosphate, as indicated by the fact that treatment with 'Dowex' and dialysis which completely removes coenzyme A, and adenosine triphosphate does not alter its activity.

Table 1

Glyoxylate and succinate formation (µmoles) from citrate by cell-free extracts of *Escherichia coli*. Total volume of reactants, 3·0 ml. Each vessel contained the amount of citrate indicated, 1 ml. of an *E. coli* extract treated twice with 'Dowex', 5 µmoles of magnesium chloride, 10 µmoles of cysteine, 0·15 ml. of 1 *M* phosphate buffer *p*H 7·4 and 0·3 ml. of sulphuric acid in side-arm. Conditions completely anaerobic. Temperature, 33° C. Time of incubation, 60 min.

| Exp. No. | Citrate | | Δ Citrate | Products | | |
|---|---|---|---|---|---|---|
| | Initial | Final | | Succinate | Glyoxylate | Carbon dioxide |
| 1 | 19·02 | 11·05 | 7·97 | 7·19 | 7·85 | <1 |
| 2 | 19·02 | 9·99 | 9·03 | 8·11 | 10·64 | <1 |

Table 2

Glyoxylate and succinate formation (µmoles) from isocitrate. Total volume of reactants, 3·0 ml. Each flask contained the amounts of substrate indicated: 20 µmoles of cysteine, 10 µmoles of magnesium chloride, 10 µmoles of phosphate buffer, *p*H 7·4 and 0·8 ml. of enzyme. Time of incubation, 40 min. Temperature, 33° C.

|---|---|---|---|---|---|
| | Initial | Final | | Glyoxylate | Succinate |
| Isocitrate | 11·5 | 5·7 | 5·8 | 6·0 | 4·7 |
| *cis*-Aconitate | 20·0 | | | 0 | 0 |
| Citrate | 20·0 | | | 0 | 0 |

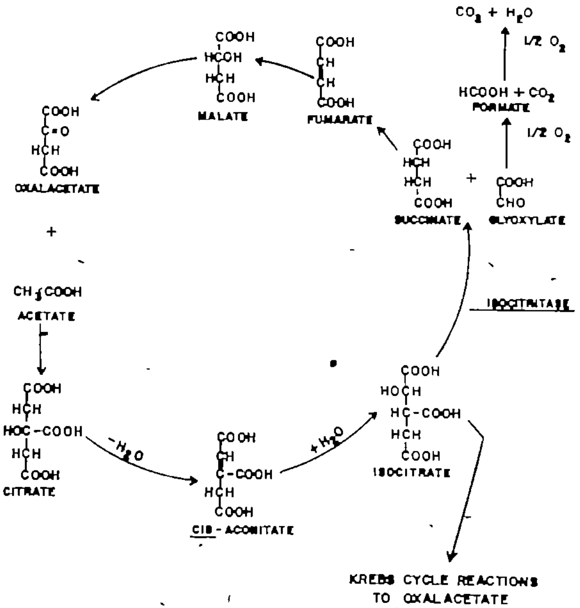

Fig. 1. An alternative cyclic pathway of acetic acid oxidation

Succinate was determined by the conventional succinoxidase procedure and glyoxylate by the method of Friedemann and Haugen[4]. To establish definitely the identity of glyoxylate, a large-scale experiment was performed and the glyoxylate isolated as its 2,4-dinitrophenylhydrazone. The material upon recrystallization from a mixture of ethyl acetate and petroleum ether had a melting point between 189° and 191° C., as did the hydrazone of authentic glyoxylate.

Radioactive citrate, prepared with the condensing enzymes and incubated with isocitritase plus aconitase, cleaved the $C_6$-acid asymmetrically to yield unlabelled glyoxylate and radioactive succinate (Table 3).

The dissimilation of the $C_6$-tricarboxylic acid to succinate and glyoxylate makes an interesting list of important intermediates from the tricarboxylic acid cycle. In this case, succinate can continue through the cycle so long as glyoxylate is available for amino-acid synthesis. According to Campbell[5], the energy produced during one turn of the cycle should be only 40 per cent of that obtained from the conventional scheme. It is also conceivable, however, that the glyoxylate is oxidized to carbon dioxide and water, in which case acetate would be oxidized to completion via a cyclic mechanism depicted in Fig. 1.

The overall picture of this series of reactions is one in which one mole of acetyl-coenzyme A enters the cycle and is oxidized to carbon dioxide and water via glyoxylate, while oxalacetate is first converted to succinate via isocitrate and is then regenerated

Table 3

Formation of radioactive succinate from labelled citrate. Total volume of reactants, 3·0 ml. Each vessel contained 1 ml. of enzyme (aconitase plus isocitritase), 10 µmoles of cysteine, 0·15 ml. of 1 *M* phosphate buffer, *p*H 7·4, 0·3 ml. sulphuric acid in side-arm and 18·52 µmoles of citrate containing 639 counts/min./µmole

| Citrate | | | Δ Citrate (µmole) | Succinate | | Glyoxylate | |
|---|---|---|---|---|---|---|---|
| Initial (µmole) | Final (µmole) | Initial specific activity (counts/min./µmole) | | Conc. (µmole) | Specific activity (counts/min./µmole) | Conc. (µmole) | Specific activity (counts/min./µmole) |
| 18·52 | 11·57 | 639 | 6·65 | 5·53 | 702 | 7·82 | inactive |

by the oxidation of succinate via fumarate and malate. It is interesting to note that some evidence already exists in the literature to support this hypothetical scheme of acetate oxidation. Campbell[6], studying the mechanism of allantoin degradation by an unidentified *Pseudomonas*, presented convincing evidence that allantoin is broken down in the following manner : allantoin → allantoic acid → glyoxylic acid + urea ; glyoxylic acid → formate + carbon dioxide ; formate → carbon dioxide + water. Since various species of the genus *Pseudomonas* contain the enzyme isocitritase and are known to contain all the other enzymes necessary for the conversion of acetate and oxalacetate to isocitrate via fumarate and malate, it is not beyond reason to assume that acetate may indeed be oxidized to carbon dioxide and water by this alternate series of cyclic reactions. Investigations are now being conducted in our laboratories to determine whether *E. coli* might oxidize acetic acid in this manner.

## Fractionation of the Deoxyribonucleic Acid of *T2r* Bacteriophage

A NUMBER of investigations indicate that the deoxyribonucleic acid (DNA) of *T2* bacteriophage plays a major part during the infection of its bacterial host and in the maintenance of genetic continuity during the multiplication process[1]. Recent work[2] has demonstrated the inhomogeneity of deoxyribonucleic acid from various sources with respect to the content of the purine and pyrimidine bases and the ease of dissociation from complexes with basic proteins. This communication describes results obtained by applying a chromatographic fractionation procedure based on the latter property to the deoxyribonucleic acid of *T2r* bacteriophage.

Large-scale lysates of the *T2r* strain were obtained by growth in aerated bottles and the bacteriophage purified by the method of Herriott and Barlow[3]. Deoxyribonucleic acid was prepared (private communication from A. D. Hershey) from the purified bacteriophage after precipitation in 95 per cent alcohol by resuspending in 0·2 *M* sodium chloride, agitating with chloroform in a blender and centrifuging to remove denatured protein. After three such treatments with chloroform, the process was repeated with a 9 : 1 chloroform – octanol mixture until no further denatured protein precipitate was formed. The deoxyribonucleic acid was then precipitated in 95 per cent alcohol, washed in 75 per cent alcohol and stored in 75 per cent alcohol at 4° C. until required.

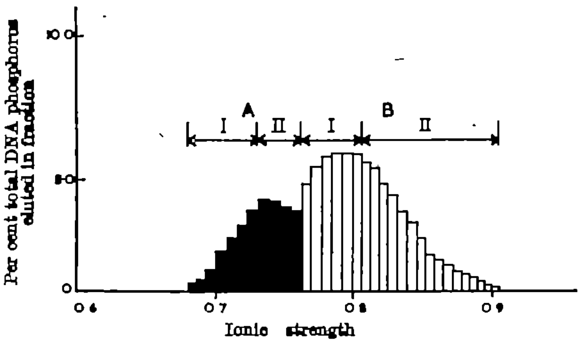

Fig. 1. Elution of *T2r* bacteriophage deoxyribonucleic acid from a column of cellulose–histone by a concentration gradient of sodium chloride at *p*H 6·8. The percentage of total deoxyribonucleic acid phosphorus eluted in a fraction is plotted against the ionic strength of the fraction

Calf thymus nucleohistone prepared by the water-extraction procedure of Crampton *et al.*[4] was extracted with 0·2 *N* hydrochloric acid and the extracted histones fractionated on columns of phosphorylated cellulose prepared by the method of Hoffpauir and Guthrie[5]. Elution by a gradient of *p*H and sodium chloride between *p*H 9·0 and *p*H 13·0 and 0·2 *M* to 1·0 *M* respectively was used, and the fraction coming from the column between *p*H 10·1 and *p*H 10·4 was attached to cellulose after denaturing by heating to 100° C. for 10 min. The diazotization method originally used by Campbell *et al.*[6] to couple albumin to cellulose was used here to couple the denatured histone to cellulose to form a material to which deoxyribonucleic acids are adsorbed at low salt concentrations and from which they can be eluted at high salt concentrations.

5–10 mgm. of the bacteriophage deoxyribonucleic acid were slowly eluted from a column of the cellulose–histone complex, 70 cm. long and 2 cm. in diameter, over a period of 40 hr. by a solution of continuously increasing concentration of sodium chloride buffered at *p*H 6·8. The deoxyribonucleic acid was eluted, as shown in Fig. 1, where it is evident that there are two distinct fractions *A* and *B* ; this was confirmed by repeating the elution on the pooled fractions *A* and *B* separately. Deoxyribonucleic acid prepared from *T2r* bacteriophage after osmotic shock[7] gave the same elution diagram, demonstrating that the method of preparation was not responsible for the bimodality observed.

That *A* and *B* are two distinct deoxyribonucleic acid species was finally confirmed by measurements of the contents of purine and pyrimidine bases which were made on the pooled fractions *A* and *B*, and also on the first and second halves of *A* (*A*I and *A*II), and on the first and second halves of *B* (*B*I and *B*II) to be eluted from the column. The contents of purine and pyrimidine bases in the fractions were measured after hydrolysis with formic acid[8] by two-dimensional chromatography (ref. 1, Hershey, Dixon and Chase). The results of base analysis on fractions from three separate fractionations are shown in Table 1, expressed briefly as the ratio of the content of adenine and thymine to the content of guanine and 5-hydroxy-

Table 1. BASE RATIOS OF *T2r* DEOXYRIBONUCLEIC ACID FRACTIONS

| | Unfractionated *T2r* DNA | Fractions | | | | | |
|---|---|---|---|---|---|---|---|
| | | *A* | *A*I | *A*II | *B* | *B*I | *B*II |
| $\frac{\text{Adenine + thymine}}{\text{Guanine + 5-hydroxymethylcytosine}}$ | 2·06 | 1·89 | 1·88 | 1·92 | 2·14 | 2·15 | 2·21 |

methylcytosine, each value being the mean of six estimations.

It appears, then, that the deoxyribonucleic acid prepared by the above methods from *T2r* bacteriophage contains two fractions, one containing approximately 30 per cent of the total deoxyribonucleic acid phosphorus, with the ratio adenine + thymine/guanine + 5-hydroxymethylcytosine approximately equal to 1·9, and the remaining 70 per cent with that ratio approximately equal to 2·15. As it is unlikely that these distinct fractions would be produced by degradation of a larger single molecule by the preparative methods used, this means that the *T2r* bacteriophage particle contains at least two different species of deoxyribonucleic acid molecule which differ in their ease of dissociation from basic protein and their content of purine and pyrimidine bases.

# Crystalline Inhibitors of Trypsin from Potato

RECENTLY, Sohonie and Ambe[1] have reported the preparation of crystalline inhibitors of trypsin from field-bean and double-bean. Unlike these inhibitors, which are comparatively stable to heat treatment, the acid extracts of potato (*Solanum tuberosum*) have been found to contain a thermolabile inhibitor[2]. We have now examined the possibility of preparing this inhibitor in quantity in a crystalline form.

A method similar to that described for the crystallization of field-bean and double-bean inhibitors[1] was successfully employed, with the difference that all the operations were carried out in the cold to minimize any loss of activity in the course of preparation. The crude inhibitor, precipitated by ammonium sulphate, yielded two fractions. One was extracted by 2·5 per cent trichloroacetic acid, while the other, insoluble in trichloroacetic acid, was removed from the residue, in 1 per cent saline. Further purification, lyophilization and crystallization were carried out essentially as described in the previous communication.

Both fractions are dirty white in colour, soluble in water and twice as potent as the inhibitors from field-bean and double-bean. These were also found to have a powerful anticoagulant action on citrated human plasma.

Heat treatment resulted in 80–90 per cent destruction of the activity. Both components gave characteristic protein reactions and were found differ widely in lysine, histidine and methionin contents.

A detailed report of the study of the differe physico-chemical properties, etc., of the potat inhibitor fractions will be published in the *Journ of Scientific and Industrial Research* (India). We a grateful to the Council of Scientific and Industr Research (India) for financing this work and for personal grant to one of us (K. S. A.).

# Interference between Variants of Pseudorabies Virus demonstrable in Tissue Culture

THE results of a series of investigations dealin with the cytopathogenic activity of pseudorabie virus have recently been reported from this Institute In these studies a strain of pseudorabies virus wa serially transferred in tissue suspensions derived fro chick embryos, and these served as a source of viru for the experiments. Destructive effects of the viru on tissue cultures made from fragments of embryoni chicken heart were recorded, and the cytopathogeni titre of virus material was used as a measure of it activity. Our present experiments have demonstrate that the virus became modified in its cytopathogeni activity for chicken cells by passages carried out i tissue suspensions of mouse embryo. The change i cytopathogenicity set in after four or five seria transfers of the virus in this tissue suspension. Th characters of virus materials serially passed in sus pensions of chicken and mouse embryonic tissu respectively are given in Table 1.

As is seen, the most striking feature of mous (*MEC*) virus is its low cytopathogenic effect o chicken cells. It should be noted that the change i properties of virus cultivated in mouse tissue wa not permanent. When *MEC* virus was serially trans ferred in embryonic chicken tissue, its destructiv effect for chicken cells gradually increased, and it ha regained its original properties within three to fiv passages.

The low cytopathogenic effect of *MEC* virus o chicken explants suggests a potential ability of thi

Table 1. CHARACTERS OF PSEUDORABIES VIRUS PROPAGATED I TISSUE SUSPENSION EITHER OF CHICK EMBRYO (*CEC* VIRUS) O MOUSE EMBRYO (*MEC*) VIRUS

| Mode of titration of virus | Virus material *CEC* No. of materials tested | Virus material *CEC* Geom. mean of titres | Virus material *MEC* No. of materials tested | Virus material *MEC* Geom. mean of titres |
|---|---|---|---|---|
| Cytopathogenic effect of virus on chicken cells | 45 | $10^{-}$[illegible] | 46 | $10^{-1\cdot15}$ |
| Cytopathogenic effect of virus on mouse cells | 4 | $10^{-}$[illegible] | 11 | $10^{-}$[illegible] |
| In young chickens intracerebrally | 1 | $10^{-}$[illegible] (*LD*50) | 1 | $10^{-4}$ (*LD*50) |
| In mice intracerebrally | 20 | $10^{-}$[illegible] (*LD*50) | 34 | $10^{-}$[illegible] (*LD*50) |

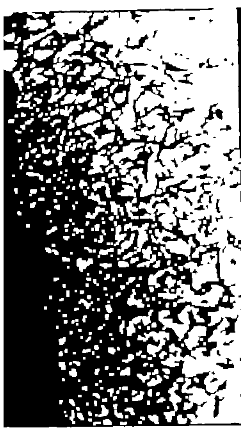

Fig. 1. Explant of embryonic chicken heart previously exposed to $10^{-4}$ dilution of *MEC* virus material and cultivated for 72 hr. with *CEC* virus of $10^{-4}$ dilution. × 75

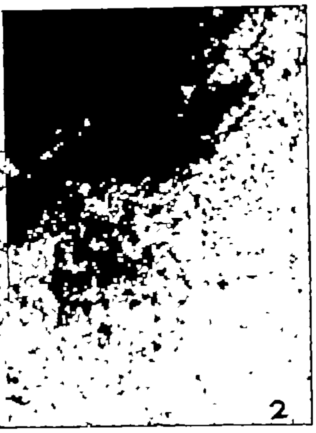

Fig. 2. Control explant cultivated for 72 hr. in the presence of $10^{-7}$ dilution of *CEC* virus. × 75. Note complete destruction of tissue culture

ariant to interfere with virus material highly estructive for chicken cells (*CEC*). To test this ossibility, fragments from embryonic chicken heart ere added to a nutrient medium containing *MEC* irus in a dilution of $10^{-3}$–$10^{-4}$ and kept at 37° for 1 hr. Simultaneously, control tissue material was lso incubated. Next day, sets of tissue explants ere made in chicken plasma from both tubes, in- ected with a serial dilution of *CEC* virus and re- ncubated for three days. As a mean value of eleven xperiments, the cytopathogenic titre for cultures ade from material treated previously with *MEC* irus was $10^{-3.7}$, whereas that of the control was $0^{-7.8}$.

Our observation is in many respects similar to that f Sabin[2], who found that after exposure to a non- ytopathogenic variant of poliomyelitis virus, epi- helial cells derived from monkey kidney had acquired limited resistance to the destructive effect of nmodified virus.

Full details of these observations will be published n the *Acta Microbiologica Hungarica*.

## Elimination of Adrenaline and Noradrenaline from the Circulating Blood

THE mode, the loci, and the extent of the inactiva- ion of the sympathetic hormones are only partly nown. The liver has been considered of prime mportance. A minor fraction of injected catechols ppears in the urine. Recently, the rather generally occurring enzyme amine-oxidase has been extensively tudied as the agent responsible for a more general, peripheral' elimination.

The method described in this preliminary communication has made possible *in vivo* studies to determine which tissues are capable of eliminating adrenaline and noradrenaline from the blood stream. Furthermore, the extent of this removal over a certain length of time has been evaluated fairly closely. Briefly, the approach was as follows. Cats were used in which any release of endogenous catechol was cut down to a minimum by transection of the cervical spinal cord and extirpation of the adrenal glands. Adrenaline or noradrenaline was administered into the circulating blood at a constant speed, either intra-arterially to the tissue area studied, or intravenously into the brachial vein. The level of contraction of the chronically denervated nictitating membrane was used as an indicator of the concentration of catechols in the systemic circulation. The minimal effective dosage of adrenaline and noradrenaline on the denervated nictitating membrane was explored by intravenous administration at a constant rate. The actual experiment was started with an intra-arterial infusion of the drugs to the tissue area studied. After some minutes, when a steady state had been established, the intra-arterial infusion was momentarily shifted to an intravenous one, without any change of the actual amount administered. From a theoretical point of view, any of three alternatives might show up:

(1) The tissue area studied might not be capable of any elimination of adrenaline or noradrenaline. In this case the amounts infused intra-arterially must reappear quantitatively at the venous side after the steady state is established. A momentary shift of the route of administration of catechols to an intravenous route would therefore not influence the concentration of catechols in the systemic circulation, and thus leave the nictitating membrane unaffected.

(2) If a fraction of the intra-arterially infused catechols was locally eliminated, less would reappear in the venous outflow than entered the area on the arterial side. A shift of the infusion to an intravenous route would then reveal the extent of the local catechol loss by a corresponding increase of the contraction of the nictitating membrane.

(3) A third possibility, recently seriously claimed (see, for example, Granaat[1]), postulates that certain tissues actively secrete catechols when influenced by the sympathetic hormones, and that actually more catechols leave the area than ever entered it.

In most of the experiments of the present series, adrenaline or noradrenaline was infused through the cannulated inferior mesenteric artery into the lower abdominal aorta of the eviscerated animal, and thus primarily directed to an area comprised of skeletal muscle and skin. The results were quite uniform. The shifting of the infusion from an intra-arterial to an intravenous route, without any change of the actual dosage, was followed by a rapid and pronounced contraction of the denervated nictitating membrane, indicating a corresponding increase in the concentration of catechols in the systemic circulation. The extent of the loss of catechols following the intra-arterial administration could then be measured by applying the ordinary procedures of a biological assay. From a quantitative point of view, the elimination of catechols in the tissue area referred to was quite impressive. In the cat the upper limit of catechol release from the adrenals is roughly 5 μgm./kgm./min. However, even during extreme physiological stress, such as asphyxia, the amounts released seldom exceed 2–3 μgm./kgm./min. (ref. 2).

In the present series, the tissue area primarily reached by the intra-arterial infusion into the lower abdominal aorta approximately equals one-third of the animal. From this, it appears that the skeletal muscle – skin area under examination during a single passage of blood eliminates up to 90 per cent of the amounts of catechols infused. This holds true so long as the dosage was kept within the physiological range of adrenal discharge. When higher concentrations of adrenaline or noradrenaline were given, a proportionally larger fraction of the amounts infused intra-arterially reached the venous side, indicating that the rate of local elimination of catechol was no longer able to cope with the increased rate of intra-arterial infusion (Fig. 1).

The extensive loss of the sympathetic hormones in this rather non-specific tissue area can only in part be attributed to amine-oxidase, since all the basic findings were still present after the administration of specific inhibitors of this enzyme. Neither was it possible to find a clear-cut distinction as to the affinity of adrenaline and noradrenaline to the unknown mechanism responsible for the observed elimination of these substances. However, noradrenaline was not eliminated more rapidly than adrenaline; rather, the contrary appeared to be the case.

Additional experiments were carried out on other tissue areas, such as the spleen, the kidneys and the intestines. The basic findings did not vary from those already mentioned, although quantitative differences require further study. In addition, the effects of graded hypoxia are under investigation, since it has been noticed that asphyxia might reduce the extent of local loss of catechol in different regions.

Hence a variety of tissues, including skin and skeletal muscle, which, as regards their status in metabolism, must be considered rather poorly differentiated, are able to eliminate adrenaline and noradrenaline from the circulating blood. It seems fair to assume that the elimination of locally released transmitter substances at postganglionic sympathe nerve endings might be still more successful.

## Metabolism of Two Aromatic Amines in the Dog

CLAYSON[1] has suggested that aromatic amines a carcinogenic by virtue of their transformation in t animal body into orthohydroxyamines. Walpol Williams and Roberts[2] have shown that 4-amin diphenyl is a potent inducer of bladder tumours the dog, and Spitz (quoted by Walpole *et al.*[2]) h obtained bladder tumours in this species wit benzidine. The purpose of this communication is show that these aromatic amines are in fact converte into orthohydroxyamine derivatives by the dog.

4 : 4'-Diamino-3-diphenylyl hydrogen sulphate an 3-hydroxybenzidine were synthesized as follow 4'-Nitro-4-aminodiphenyl was converted by oxidatio with alkali and ammonium persulphate to sodiu 4'-nitro-4-amino-3-diphenylylsulphate (found: lo on drying, 13·7; S, 8·4; $C_{12}H_{9}O_{6}N_{2}NaS.3H_{2}$ requires loss 14·0; S, 8·3 per cent); 4'-nitro- amino-3-hydroxydiphenyl hydrochloride monoh drate (found: C, 51·2; H, 4·5; N, 10·2 $C_{12}H_{11}O_{3}N_{2}Cl.H_{2}O$ requires C, 50·8; H, 4·6; N 9·9 per cent) obtained by hydrolysis was cha acterized as the diacetyl derivative (found: N, 8·8 $C_{16}H_{14}O_{5}N_{2}$ requires N, 8·9 per cent), melting poin 189–190°. Sodium 4'-nitro-4-amino-3-diphenylyl sulphate was reduced with ferrous sulphate an ammonia to 4 : 4'-diam ino-3-diphenylyl hydro gen sulphate (found: C 51·1; H, 4·2; N, 9·8 S, 11·2; $C_{12}H_{12}O_{4}N_{2}$ requires C, 51·4; H 4·3; N, 10·0; S, 11· per cent), which wa hydrolysed to 3-hydroxy benzidine (found: N 13·8; $C_{12}H_{12}ON_{2}$ re quires N, 14·0 per cent) melting point 182–184° tribenzoate (found: C 77·3; H, 4·8; N, 5·7 $C_{33}H_{24}O_{4}N_{2}$ requires C 77·3; H, 4·7; N, 5· per cent), melting poin 270–271°. 4-Amino-3-di phenylyl hydrogen sul phate and 3-hydroxy-4 aminodiphenyl were pre pared by the method o Boyland and Sims[3].

Urine from dogs fe 4-aminodiphenyl (20 mgm./day) has bee chromatographed o paper in no fewer tha ten solvent systems. I

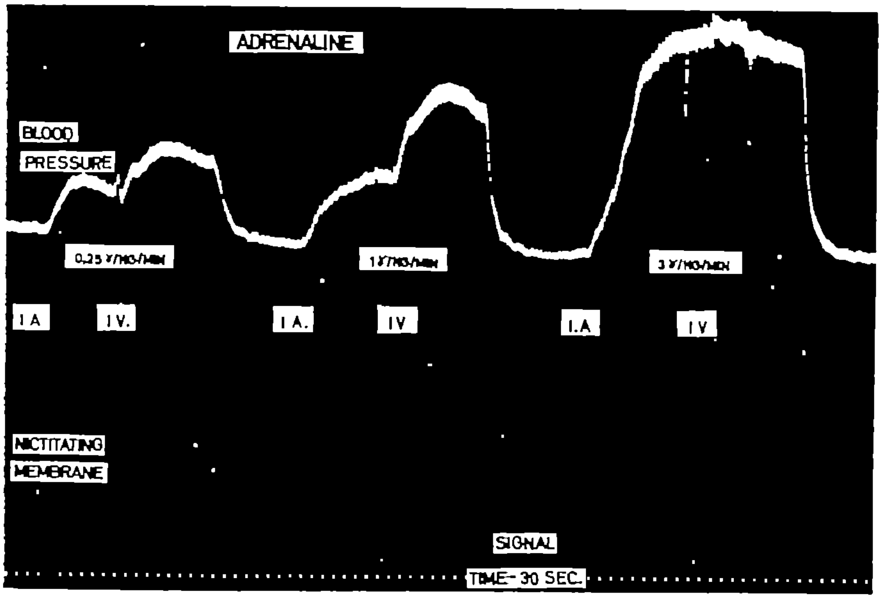

Fig. 1. Spinal cat, 3 kgm. Adrenals extirpated. Blood pressure at outset, 70 mm. mercury. Minimal effective dose of adrenaline on denervated nictitating membrane 0·1 μgm./kgm./min. intravenous. The records show the effects of three successive periods of adrenaline infusion into abdominal aorta versus intravenous infusion of the same concentrations

cases, only two spots could be demonstrated by raying with a solution of *p*-dimethylaminobenz-lehyde. A very faint spot corresponded to 4-amino-henyl. This spot was strengthened when ether tracts of the urine were examined. The second re intense spot travelled at the same rate as amino-3-diphenylyl hydrogen sulphate; hydrolysis the urine by boiling with acid gave a new spot rresponding to 3-hydroxy-4-aminodiphenyl.

Urine from dogs fed benzidine (500 mgm./day) was romatographed on paper in ten solvent systems. ree major and a number of other spots were monstrated with the *p*-dimethylaminobenzaldehyde ray. Benzidine and 4 : 4′-diamino-3-diphenylyl drogen sulphate were shown to be important etabolites of the amine. 3-Hydroxybenzidine was own to be present as a minor metabolite in some mples of urine. The other metabolites have not t been identified.

Continuous ether extraction of the urine of a dog d benzidine (500 mgm./day) for ten days enabled nzidine (400 mgm.; 8 per cent of the dose) and hydroxybenzidine (85 mgm., 1·5 per cent) to be lated. The benzidine, melting point and mixed elting point 124°, was characterized as the toluenesulphonate, melting point 241–242°, mixed elting point 242–243°. The monohydroxybenzidine, elting point 180–183°, was characterized as its ibenzoate, melting point 269°, mixed melting point 0–271°.

This work will be reported in detail later. We wish thank Dr. G. M. Bonser for making available the ological material.

## Synergism in the Chemotherapy of *Eimeria tenella*

IN 1954, Lux[1] investigated the possibility that tent inhibitors of *Eimeria tenella* might be found nong compounds, other than sulphonamides, which terfered with the *p*-aminobenzoic acid – folic acid etabolic sequence. Lux found that a group of 4-diamino-pyrimidines possessed anticoccidial activity, one of the most active of the series being 4-diamino-5, *p*-chlorophenyl, 6-ethyl pyrimidine Pyrimethamine', 'Daraprim'). He noted, furtherore, that this compound, when used in combination ith certain sulphonamides, had a marked synergistic fect.

At Weybridge, we have extended these observations ith the view of developing effective systems of emotherapy for disease caused by *Eimeria tenella*. the past, 'Sulphamezathine' (sulpha-dimethylrimidine) has in our experience proved most satistory for treatment under practical conditions; t its use can be criticized on the grounds that the ncentration necessary to obtain a maximum theratic effect is sufficiently high to cause some degree of inappetence, that occasional toxicity is observed[2], and that the full therapeutic concentration is liable to cause temporary inhibition of the parasite, development being merely delayed until treatment terminates[3,4]. Our observations, which have confirmed those of Lux[1], have shown that, although 0·01 per cent 'Daraprim' in the food affords only partial protection against *E. tenella*, the synergism between this substance and 'Sulphamezathine' permits the reduction of the concentration of both compounds to a fraction of that ordinarily needed for therapeutic control. Thus, in the presence of as little as 0·0025 per cent 'Daraprim' in the food, the concentration of 'Sulphamezathine' may be reduced to between $\frac{1}{8}$ and $\frac{1}{16}$ of that normally required for complete protection.

Temporary inhibition, with delayed clinical manifestations of disease, occurs with a mixture of 0·01 per cent 'Daraprim' and 0·05 per cent 'Sulphamezathine', but not when the concentration of 'Daraprim' in the mixture is reduced to 0·0025 per cent. This suggests that the combination of drugs at these low concentrations has a markedly selective effect on the later stages in the life-cycle of the parasite, leaving unimpaired the earlier stages, the development of which Kendall and McCullough[3] have shown to be essential for effective chemotherapeutic control.

These findings are likely to be of marked practical importance, and it seems that the use of the synergistic combination will avoid the difficulties associated with the present use of the sulphonamides.

The synergistic action on *E. tenella* of 'Daraprim' and 'Sulphamezathine' can probably be explained as the effect of two antimetabolites which act sequentially at different stages in the same metabolic pathway, at the points at which *p*-aminobenzoic acid and folic and folinic acids are concerned.

This would suggest a close analogy between the metabolism of *E. tenella* and those species of *Plasmodium* on which 'Daraprim' and some sulphonamides also exert a marked synergistic effect[5]. *p*-Aminobenzoic acid has already been shown to be an essential metabolite for *E. tenella* by the observation of Horton-Smith and Boyland[6] that the action of 'Sulphamezathine' may be antagonized by *p*-aminobenzoic acid. No facts are available on the importance of folic and folinic acids for *E. tenella*, although 'Daraprim' is regarded as an antagonist of folic and folinic acids in several other biological systems[7].

If, in fact, the metabolism of *E. tenella* is similar to that of the plasmodia, other anti-malarials may be able to replace 'Daraprim' in synergistic combination with sulphonamides or other drugs of known coccidiostatic value.

Studies on the above lines are proceeding.

# A Study of Normal Human Cerebrospinal Fluid by the Immuno-Electrophoretic Method

THE immuno-electrophoretic method[1] allows the definition of the constituents of a mixture of antigenic substances by means of their relative electrophoretic mobilities, and their enumeration, by specific precipitation, by means of a homologous immune serum. The study of normal human serum by this method has allowed the enumeration of at least sixteen different constituents[2].

We have studied, by the same method, normal cerebrospinal fluid concentrated by ultra-filtration[3], by using horse immune serum (No. 31) anti-normal human serum, which has been used in the study of human serum. In a parallel manner we have submitted the same samples of cerebrospinal fluid to ordinary electrophoresis on agar under the same conditions as used for immuno-electrophoretic analysis. The agar gels were then dried, and the protein and lipid constituents were stained *in situ* by methods similar to those used previously[4].

The plain electrophoretic analysis in a gelified medium shows (Fig. 1) that the cerebrospinal fluid contains: a substance which migrates more quickly than albumin; much albumin; a small amount of α-globulins; $\beta_1$- and $\beta_2$-globulins and a small amount of γ-globulins.

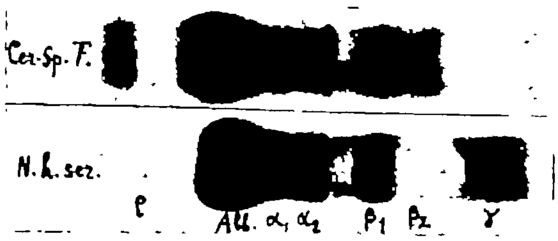

Fig. 1

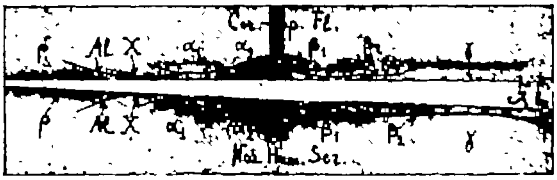

Fig. 2

The immuno-electrophoretic analysis (Fig. 2) allows us to distinguish the following: a constituent which migrates more rapidly than albumin and which would seem identical with the ρ-constituent of blood serum[2]; serum albumin; a constituent having the same mobility as albumin which is probably identical with the χ-constituent in blood serum[2]; one or probably two $\alpha_1$-globulins; three $\alpha_2$-globulins; at least one $\beta_1$-globulin; a single antigenic constituent having, however, two different migration-rates. This latter corresponds to the $\beta_2$-globulins and the small amount of γ-globulins which corresponds to the slow γ-globulins of the serum.

As we have used a total immuno-serum human antiserum, we could only distinguish in the cerebrospinal fluid constituents existing in the serum; there may also be other constituents specific to the cerebrospinal fluid. Our results do, however, demonstrate that the distribution of protein constituents in the cerebro-spinal fluid is not the same as in the ser itself.

Detailed results will be published in the *Bull. S Chim. Biol.*

# Effect of Heat Stress on Serial Reaction Time in Man

EXPERIMENTAL studies of the effects of ambie temperatures on simple reaction time have suggest that there may be a negative correlation betwe simple reaction time and temperature, but resu appeared to be rather inconclusive. In fact Teichne in a review of studies of simple reaction tin concludes that ambient temperatures between − 5 and 117° F. have little or no effect on either simp reaction time or more complex reaction times.

In a series of experiments on the effects of ambie temperatures ranging from 90° to 104° F. (90–95 p cent saturation), we had occasion to study the effec of such temperatures on both simple reaction tir and serial reaction time. In serial reaction time t signals are presented to the subject continuously wi irregular occurrence of the signals to action, a without the warning signals customary in expe ments on simple reaction time. It may reasonab be argued that serial reaction time is a more realist measure than simple reaction time, since in the ski of everyday life we are seldom given warning of t arrival of a significant stimulus.

The apparatus used in these experiments was t Cambridge visual vigilance test[2], coupled to a phot electric cell and a pulse-height discriminator operatu a clock-starting relay. This gave a very accura measure of reaction time.

Seven subjects were tested over a period of fi days, serial reaction time being measured before ent into the heat chamber, after one hour exposure the above range of temperatures, and after two hou exposure. For each measurement of reaction tin the subject was presented with a large number stimuli in a short time (forty stimuli in 5 min. random order). The mean serial reaction times a shown in Table 1. It will be seen that the rise reaction time under heat stress is small but statistical significant.

Table 1

| | Mean serial reaction time (sec.) | *P* |
|---|---|---|
| Control | 0·247 | |
| First hour | 0·256 | |
| Second hour | 0·267 | |
| Control v. first hour | | 0·05* |
| Control v. second hour | | 0·01† |
| First v. second hour | | 0·05* |

* Significant.
† Highly significant.

From these experiments we conclude that serial action time offers a clear-cut index of psychomotor ange under heat stress of this order.

## Fixation of Iodine in Selenium

THE following observations were made in carrying t some tracer experiments on the selenium–iodine stem, using the radioactive isotope iodine-131.

It was found that iodine could be adsorbed on to lenium powder from a solution containing iodine-31, and measurements of the total γ-ray activity a sample of the selenium were made: (i) after e powder had been thoroughly dried; (ii) after it d been melted and at once cooled to an amorphous lid; and (iii) after further heating in an open tube r 7 hr. at 550° C.

No significant differences were found among the ree activities, from which it was concluded that s than 1 per cent of the iodine initially present was moved during the heat treatment. An autoradio-raph of a section through the specimen at the end f the experiment showed a macroscopically uniform istribution of iodine-131 activity.

This evidence supports the generally accepted view hat halogen atoms can be bound in the selenium tructure, probably at the ends of chains of selenium toms. If it is assumed that iodine and bromine ehave similarly in this respect, this conclusion does ot agree with that of Nijland[1], who states that o stable bonds exist between selenium chains and romine atoms.

## Production of Anisotropy in a Permanent Magnet by Pressure

H. P. J. WIJN and others[1] have described a novel nethod of making 'Ferroxcube' with a square ysteresis loop. Glass with a higher coefficient of xpansion than the 'Ferroxcube' was fixed to a ring-haped sample at an elevated temperature; the esulting strain at room temperature produced a quare hysteresis loop. An experiment has been per-ormed to show that a similar effect is possible with permanent magnet alloy.

Since a large magnetostriction appeared necessary, 5 per cent cobalt steel was chosen for the experiment. The magnetostriction is positive, and in consequence longitudinal tension or a lateral pressure will avour a square loop. A lateral pressure was obtained n a bar of cobalt steel about 1¼ in. long and ¼ in. in liameter in the following manner. A hole 0·002 in. ess in diameter than the cobalt steel was made in a tainless steel block. This block was heated to 450° C., he cobalt steel was cooled in liquid air and the tainless steel block was shrunk on to the cobalt steel pecimen. The cobalt steel had been previously hardened, aged at 150° C. and cooled in liquid air before testing, so that any changes in properties after the shrinking are likely to be due to the pressure and not to the temperature cycle during the shrinking operation.

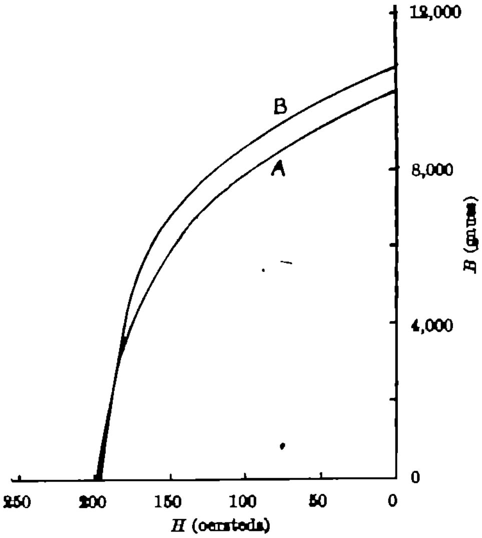

Fig. 1. (*A*) Normal curve; (*B*) under compression

The test values obtained are shown in Fig. 1.

The improvement obtained by pressure, although not spectacular, is amply demonstrated.

## Localized Corona Discharges at a Negative Electrode

THE form of the d.c. corona discharge in air differs according to the polarity of the electrode near which it occurs. In an electrode system comprising a wire and a coaxially mounted ring, the discharge appeared as a continuous bright sheath around the wire when it was positive, but as a series of separate tufts when it was negative with respect to the ring.

In an investigation of the latter effect, a jet of mercury was substituted for the wire, giving a clean and smooth electrode surface which was also moving rapidly with respect to the electric field. With the jet negative to the ring, no stationary tufts were observed. It was confirmed by photography with a flash of microsecond duration that the jet, though not accurately parallel-sided, was smooth in the region where discharges occurred. The influence of the moving layer of air at the surface of the mercury jet was simulated by blowing air from a nozzle along a wire at the surface of which tufted discharges were occurring, the effect being that the tufts persisted but with some vibration along the wire.

The nature of the light emitted was investigated with a photomultiplier, wide-band amplifier and oscilloscope and was found to be similar in the cases of both jet and wire. It consisted of pulses, of duration about $10^{-7}$ sec., separated by irregular intervals having durations of microsecond order.

These results suggest that the localization of the negative d.c. corona is an effect due to the electrode, and that the mechanism of the discharge is not much different whether it is localized or not. It is surmised that each individual discharge is associated with a cathode spot which, in the case of a stationary electrode, maintains its position by thermionic emission.

## Specific Heat and Heat of Wetting of Wood

Kelsey and Clarke[1] have recently discussed the variation with temperature of the integral heat of sorption of water by wood ($\Delta H$), and its bearing on the specific heat ($c_m$) of wood containing $m$ gm. of moisture per gm. of dry wood. Empirically, it is found that $c_m$ is greater than the specific heat ($c$) calculated from the specific heats and proportions of the components, assuming a simple mixture law[2]. This effect is not confined to cellulosic materials, but has been observed on starch[3], gelatin[4], dried foods[5] and other hygroscopic substances. The suggestion has previously been made[5] that the excess specific heat could be accounted for in terms of the change in $\Delta H$ with temperature ($T$); Kelsey and Clarke quote the appropriate thermodynamic equation as

$$c_m = \frac{1}{1+m}\left\{mc_w + c_0 + \left(\frac{\partial \Delta H}{\partial T}\right)_{p,m}\right\}$$

where $c_w$ is the specific heat of the water, and $c_0$ is the specific heat of the dry wood. Putting $c_w = 1$, and noting that

$$c = (m + c_0)/(1 + m), \qquad (1)$$

then

$$c_m - c = \Delta c = (\partial \Delta H/\partial T)/(1 + m) \qquad (2)$$

where $\Delta c$ is the excess specific heat.

During the past two years, we have measured the specific heat and heat of sorption of a batch of beech sawdust as a function of temperature and moisture content[2,6]. Our results enable a direct check on equation (2) to be made (Table 1).

Measurements at temperatures of 30, 40, 50, 60° C. gave $c_0$ = 0·31, 0·32, 0·33 and 0·34, respectively. The values of $\Delta c$ in Table 1 were obtained by computing $c$ from equation (1) and subtracting it from the observed specific heat ($c_m$). The values $(\partial \Delta H/\partial T)/(1 + m)$ were obtained by plotting $\Delta H$ a given moisture content against temperature, fitt a curve by eye and differentiating graphically. T error in the measurement of $c_m$ is estimated to about 0·005; but owing to the accumulation errors in the measurements, in drawing the curv and in the graphical differentiation, the uncertain in $(\partial \Delta H/\partial T)/(1 + m)$ is at least 0·01. To the accura of the results, therefore, the values in Table 1 satis equation (2) completely.

Table 1

| $m$ | $T$ (° C.) | $\Delta c$ | $(\partial \Delta H/\partial T)/(1+m)$ |
|---|---|---|---|
| 0·107 | 30 | 0·02 | 0·02 |
| | 40 | 0·02 | 0·02 |
| | 50 | 0·02 | 0·03 |
| | 60 | 0·04 | 0·05 |
| 0·140 | 30 | 0·02 | 0·02 |
| | 40 | 0·03 | 0·03 |
| | 50 | 0·03 | 0·04 |
| | 60 | 0·06 | 0·05 |
| 0·216 | 30 | 0·03 | 0·03 |
| | 40 | 0·04 | 0·04 |
| | 50 | 0·05 | 0·06 |
| | 60 | 0·08 | 0·07 |
| 0·310 | 30 | 0·04 | 0·05 |
| | 40 | 0·05 | 0·06 |
| | 50 | 0·06 | 0·07 |
| | 60 | 0·09 | 0·09 |

Equation (1) is often used for calculating the spec heat of wood for technical applications[7]; but tl procedure can evidently lead to errors of the ord of 10 per cent. The general agreement between o results and those of Kelsey and Clarke, obtained an entirely different species, is good, and sugges that the specific heat of wood containing moistu will not depend greatly on species. This suggesti is supported by the work of Dunlap[8], who found tl specific heat of dry woods to be practically ind pendent of species.

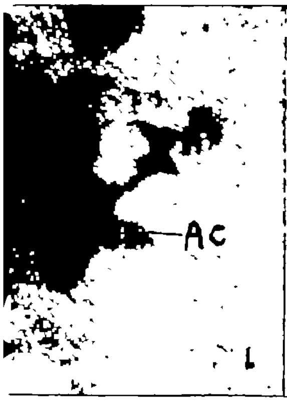
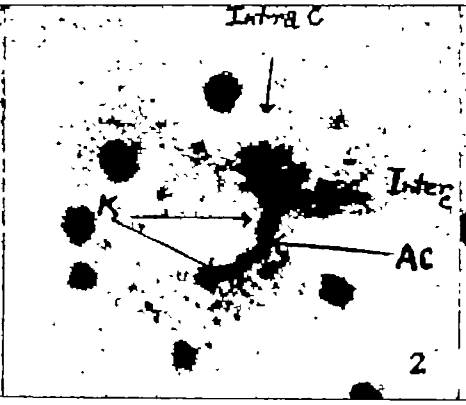
## Canals within Pancreas Cells

THERE have recently appeared in *Nature* and els where articles by Lacy[1] describing canals withi pancreas cells. These he believes represent the Gol apparatus; and he has published[2] an electron phot micrograph purporting to show one of these "Gol canals" in section.

In point of fact, intracellular canals have bee described in the pancreas by numerous observer especially Muller[3] and Holmgren[4]; but the poss bility that the Golgi apparatus of the pancreas cell may be no other than a deposit of silver or osmiu upon the pre-existing canals of a functional intra cellular duct system seems to have been overlooke by most workers, with the exception of Saguchi Lacy, however, has overlooked Saguchi's classic study, though he has undoubtedly re-described th same intracellular canals depicted by the Japanes worker. Further, Lacy assumes in contradistinctio a physiological function for his "Golgi canals" b postulating a role for them in a "lipoidal secretio cycle". He also claims that his discovery of th canals necessarily disproves the Golgi artefact theory

In order to test Saguchi's conclusions, I hav attempted to inject the intracellular canals from th pancreatic ducts with a 'mass' consisting of a lake blood medium. After sectioning, the hæmatin wa revealed by staining the preparations with a hæm atoxylin solution. This procedure was found to giv a brilliancy and precision hitherto unobtainabl





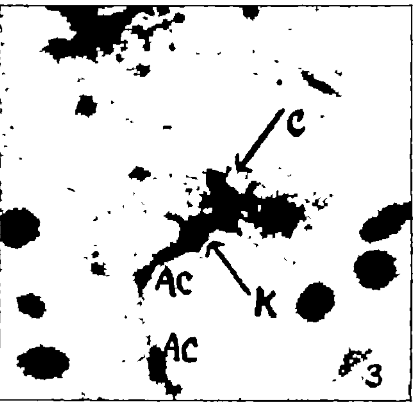


Fig. 1. Injected cat pancreas. Two intracellular saccular 'cisterns' communicate with the acinar cavity ($AC$) by fine canals. × 3,000

Fig. 2. Transverse section of an injected acinus. Acinar cavity ($AC$); vacuoles of Kupffer ($K$); intracellular canaliculi (Intra $C$); intercellular canaliculus (Inter $C$). × 1,500

Fig. 3. Intracellular canals and 'cisterns' ($C$) drain to the acinar cavity ($AC$) through a Kupffer vacuole ($K$). × 1,500

ith simple carmine gelatine media. Details of this ethod will be published elsewhere.

In the sections, in numerous instances, both inter- llular and intracellular canals can be seen clearly mmunicating with the acinar cavity. For the most rt the intercellular canaliculi end blindly but have teral extensions which enter the cells and run among he zymogen granules. In other instances fine canals ring between the zymogen granules unite and drain a a single intracellular canal to the exterior. Some- mes the cells contain a single irregular saccular pace within the cytoplasm and this may receive maller tributaries from among the granules. These ccular spaces then drain to the acinar cavity by eans of a fine canal. Fig. 1 shows two examples f this arrangement revealed within adjacent acinar ells.

The secretion vacuoles of Kupffer, observed also y Müller and Saguchi, occur frequently in my aterial. They usually receive one or more intra- ellular canals (Fig. 2). In Fig. 3 some intracellular ccular spaces together with tributary branches enter Kupffer vacuole before draining to the acinar avity.

The saccular spaces revealed by this method appear be interposed on a more delicate and elaborate ystem of intracellular canals which penetrate the ell in all directions. Their appearance suggests that hey may act as cisterns for the temporary storage f materials destined for secretion. Undoubtedly ese saccular spaces are often preserved in ordinary reparations, but their communications remain in- isible and the isolated spaces give the impression f structures intrinsic to the cytoplasm. Similar aces have often been described in endocrine cells, s in the curious 'signet ring' basophil pituitary cell. hese spaces are possibly homologous structures for e holding of partly elaborated secretions, and would erve a purpose similar to the thyroid vesicle, but n an intracellular scale.

I would suggest that my findings support Saguchi's elief that a functional duct system of exogenous rigin occurs within the acinar cells of the pancreas. he finest ramifications of this system appear com- ensurate with the smallest zymogen granules, and ey thus agree in size with the canals recently hotographed with the electron microscope.

It is becoming increasingly clear from recent udies[6,7] that the metallic impregnation techniques so long used as an indicator of the 'Golgi apparatus' do in fact colour quite unrelated and dissimilar objects in different cells. Lacy has shown that the canals within the acinar cells are preserved and blackened by a number of Golgi techniques, but reliance on the supposed specificity of these methods has, I believe, led Lacy into a mistaken conception of the nature of his canals.

## Behaviour of Young and Old Females of the Black-fly, *Simulium ornatum* Mg.

CONSIDERABLE attention has been devoted to devising means of determining the age of mosquitoes[1] and tsetse flies[2] in the course of studies on their ecology and behaviour, particularly in relation to disease transmission. By observing the distribution and quantity of fat-body in the black-fly, *Simulium ornatum* Mg. (Diptera, Simuliidae), it has now been possible to achieve some degree of age determination in this blood-sucking insect also.

Female flies taken on cattle in the field can be divided into two main groups on dissection, namely, those with visible fat-body particularly in the anterior abdominal segments (group $A$), and those with no fat-body, except in small amounts in the posterior abdominal segments (group $B$). Some 0–10 per cent of the flies in particular samples were intermediate and could not be allocated to either group. On emergence from the pupa, females invariably possessed abundant fat-body. Laboratory studies on the disappearance of the fat-body in flies of known age suggest that group $A$ consisted of young flies, perhaps not more than seven to ten days old, and that the $B$ group was composed of individuals at least ten days old. Residual ripe eggs, conclusive evidence of a previous complete gonotrophic cycle, were found only among *B* flies. Since in *S. ornatum* a blood feed is necessary before ripe eggs are produced, it is concluded that some, and probably most, of the *B* flies had taken a previous complete blood meal, whereas none of the *A* flies had done so.

It is interesting to note that the changes in the amount of fat-body in female *S. ornatum* appear to form the converse of the situation found in male tsetse flies, where the initially small reserves may be augmented considerably by synthesis of fat after blood feeds have been taken[3].

The practical value of using this method of age classification is seen in the following data, in which the age of flies landing on cattle during a variable period between morning and early evening is compared with the age of those landing on cattle during the last ½–1½ hours of daylight. The pooled results for sixteen days in 1954 show that old flies formed a higher proportion of the catch during late evening (see Table 1). The greater number of flies containing residual ripe eggs in the late evening catches confirms this finding (Table 2). When the days are considered separately, a significant late-evening increase in the proportion of old flies occurred on only eight of these days ($P$ within range 0·01 to < 0·001). On the sixteen days the total catch of *S. ornatum* per unit time on cattle was often greater in late evening than during the day, paralleling the situation shown for *S. venustum* Say on man in Canada[4]. This increase in activity thus coincided with the occurrence of a greater proportion of old flies in the catch, and the number of old flies visiting the cattle per unit time became 1·2–12·0 times greater in late evening than during the day.

Table 1

| Flies taken during 1–3 hr.* within the period 10.00–18.00 hr. | | | Flies taken during ½–1½ hr. in late evening (18.00–21.00 hr.) | | |
|---|---|---|---|---|---|
| *A* Flies | *B* Flies | Unclassified | *A* Flies | *B* Flies | Unclassified |
| 724 | 253 | 29 | 579 | 542 | 23 |

Ignoring unclassified flies, $\chi^2 = 110·88$; $P = < 0·001$.

* The longer period was necessary in order to obtain fly numbers high enough for statistical analysis.

Table 2

| Flies taken during 1–3 hr. within period 10.00–18.00 hr. | | Flies taken during ½–1½ hr. in late evening (18.00–21.00 hr.) | |
|---|---|---|---|
| No. containing residual eggs | Total flies | No. containing residual eggs | Total flies |
| 37 | 1,006 | 111 | 1,149 |

$\chi^2 = 29·08$; $P = < 0·001$.

It would appear that in the case of an organism transmitted by the bite of *S. ornatum*, a susceptible host would have been exposed to a far greater number of potentially infective bites per unit time in late evening than during 10.00–18.00 hr. on the days in question.

The readiness of young and old flies to bite a cow was compared by recording the frequency with which fresh blood was found in the gut of flies of each group, which were given the opportunity to bite during approximately 10 min. of each hour of the observations. The results of dissecting 3,702 flies taken on eighteen days in 1954 (Table 3) show that old flies bit the cow almost twice as frequently as did young flies on average over the period.

Table 3

| | *A* Flies | *B* Flies |
|---|---|---|
| No. flies taken<br>No. containing fresh blood | 2,448<br>80<br>(=3·27 per cent) | 1,254<br>80<br>(=6·38 per cent) |

$\chi^2 = 18·67$; $P = < 0·001$.

This work was financed by a grant from th Agricultural Research Council. The full results wi be published elsewhere.

## Physiology of the Heart of a Scorpion

IN view of the fact that scarcely anything is know about the physiology of the hearts of arachnid except that of *Limulus*[1], the present investigatio on the nature of the heart of *Palamnaeus bengalensi* C. Koch and the effects of stimuli, *p*H and drugs o it was undertaken. The hearts were isolated in saline (*p*H 6·3) containing sodium chloride, 0·65 gm. potassium chloride, 0·03 gm., and calcium chloride 0·03 gm. in 100 c.c. of distilled water and the *p* maintained with a phosphate buffer. The hæmolymph was found to be on the acid side of neutrality in agreement with Maluf's statement[2]; hence th selection of an acidic saline. Heart-beat after isolation was slow and irregular for nearly ten minutes On recovery, it showed a high degree of automati movement with incessant rhythmic and simultaneou beat throughout the myocardium, at a rate of 56–62 min. at room temperature (25–27° C.), without res pauses. After 10–12 hr. its rate and amplitude fel gradually. After temporarily inhibiting the heart rate by such mechanical stimuli as shaking the salin or pressing the heart, there was acceleration of th rate of beat. Isolated pieces of the heart beat fo some time.

Both increasing and decreasing the *p*H of th saline with phosphate buffers depressed the heart rate, and increase of temperature accelerated th heart-rate. The upper limit was 80–85 beats/min at 42° C.; the lower limit on cooling was 4–5 beats min. at 5° C., but it recovered on increasing th temperature.

Stimulation of the brain and ventral nerve cor by passing electrical current did not affect the rat of beat of the heart *in situ*. It also had no effect o direct application to the heart, up to 2 V. Furthe increase in the intensity of the stimulus in the latte case stopped the heart-beat. On switching off, th heart-beat reappeared after about 15 min. Electricall stimulated hearts were not used for drug experiments

The effects of various drugs were observed on heart both *in situ* and isolated. Acetylcholine at $10^{-5}$ dilution or stronger depressed the rate of beat, but th heart recovered after washing with saline. At highe dilution acetylcholine had no effect. By first treatin hearts with higher dilutions and then graduall creasing the concentration, tolerance to acetyloline up to $10^{-4}$ dilution was observed. The action acetylcholine was potentiated by physostigmine $0^{-4}$). Histamine ($10^{-4}$) accelerated the heart-rate d antagonized the action of acetylcholine. Adnaline ($10^{-3}$) accelerated, atropine ($10^{-4}$) inhibited d ether (half and fully saturated) had no effect the heart-beat. On many occasions the best agent r reviving a collapsing heart was warm saline, which s added in drops to the heart container. The time recovery varied from five to fifteen minutes.

According to the classification of hearts by Needham[3], the scorpion heart may be put among the yogenic types.

A detailed account of this work will be published sewhere. I am indebted to Prof. M. B. Lal, Univerty of Lucknow, for his interest and to Prof. K. N. Jha, Medical College, Cuttack, for help in carrying t some of the experiments. I thank the B.S.I.R., rissa, for financial aid.

## Apparent Resistance of a Snail to Infection in the Gold Coast

In recent years, detailed studies have been conucted on schistosomiasis and its snail vectors in e Gold Coast. The results of surveys throughout e territory show that although *Schistosoma haematoium* and *S. mansoni* are both endemic, the former fection, together with its snail hosts, *Physopsis fricana* and *Bulinus* sp., *sensu stricto*, is considerably ore widespread than the latter and its planorbid ector, *Biomphalaria pfeifferi*[1].

During snail surveys it was observed that *Bulinus Pyrgophysa*) *forskalii* is widely distributed, and as his species is a vector in the Gambia[2] and in Mauritius[3,4], its role in the local transmission of histosomiasis may well be suspected. The results f field observations in the Gold Coast were equivocal. or example, at Dabala, Adutor and other villages the Tongu district, a high incidence (50–90 per ent) of *S. haematobium* infection occurs in the local hildren. In this area only *B.* (*P.*) *forskalii* could be und, despite a thorough search during both wet nd dry seasons for the principal vectors, *P. africana* nd *Bulinus* sp., *s.str*. Thus in the Tongu district, at east, the results of the field surveys pointed to . (*P.*) *forskalii* as the potential vector. In other istricts *B.* (*P.*) *forskalii* alone were commonly ecorded in ponds used frequently by people in whom . *haematobium* infection is very rare. In these istricts there is no evidence that effective transmission occurs in the presence of *B.* (*P.*) *forskalii* lone. None of several thousand *B.* (*P.*) *forskalii* ollected in the Gold Coast has been found infected ith mammalian schistosome cercariæ.

In view of these findings and the conflicting evidence egarding the susceptibility of *B.* (*P.*) *forskalii* to . *haematobium* in other African territories[4], conrolled transmission experiments using laboratoryred snails are being undertaken in Accra. The esults of four typical observations are described elow.

(1) Twenty half-grown *B.* (*P.*) *forskalii* were exposed for 5 hr. to large numbers of miracidia of *S. haematobium* derived from infected children at Pokoasi, near Accra. At frequent intervals from the twenty-second day until the forty-second day after exposure, the snails were examined for the emergence of cercariæ, but none was observed during the period. Thereafter the snails were killed and dissection showed them to be free of parasites.

(2) Thirty similar snails were exposed on three successive days in the same manner as those in the first experiment. Using the same method of detecting infection, it was again observed that none of twenty-five snails that survived the period of observation was infected.

(3) Twenty *B.* (*P.*) *forskalii* and twenty *P. africana*, bred in the laboratory, were exposed for 4 hr. to *S. haematobium* from Pokoasi children. During the period of exposure, both species were kept in the same dish. Eighteen *P. africana* snails afterwards shed cercariæ, but none of the *B.* (*P.*) *forskalii* became infected.

(4) Twenty-five *B.* (*P.*) *forskalii* and twenty *Bulinus* sp., *s. str.*, were placed together in the same dish and exposed overnight to *S. haematobium* miracidia derived from children in a district where both species are found. All the *Bulinus* sp. later shed cercariæ but none of eighteen surviving *B.* (*P.*) *forskalii* became infected.

In summary, attempts to infect laboratory-bred *B.* (*P.*) *forskalii* from the Gold Coast with local strains of *S. haematobium* were unsuccessful even though it seemed that the parasites could develop readily in both *P. africana* and *Bulinus* sp., *s. str.*, snails also bred in the laboratory.

The varying susceptibility of the Bulininae and Planorbinae to *S. haematobium* and *S. mansoni* respectively is a puzzling problem not yet understood. For example, an important snail host in one country may be refractory or only slightly susceptible to the same species of schistosome from another region[5]. Alternatively, snails of the same species in different regions may be either susceptible or resistant to local strains of the same schistosome. In the Sudan, Archibald and Marshall[6] record that *P. africana* were refractory to *S. haematobium*; yet these snails are the principal vectors of the parasites in the Gold Coast. In respect of *B.* (*P.*) *forskalii* and its relationship to *S. haematobium*, a similar picture seems to exist. As already mentioned, *B.* (*P.*) *forskalii* from the Gambia and Mauritius are susceptible to *S. haematobium*, but in the Gold Coast and in Tanganyika[7] they appear to be refractory.

The explanation of the susceptibility or resistance of the potential vectors to their schistosome parasites must lie either with the snails or with the parasites. First, as our knowledge of the taxonomy of the snail hosts is still rudimentary, it may be argued that the 'species' of snails in the different regions are morphologically or biologically distinct and accordingly are either susceptible or resistant to infection. If this is true, *B.* (*P.*) *forskalii* in the Gold Coast may be different from *B.* (*P.*) *forskalii* in the Gambia and in Mauritius, although this difference, if it exists, is not yet determined. Secondly, it may be argued that several strains of *S. haematobium* exist, each having an affinity—perhaps to the extent of being specific to a certain host—for a particular species of snail. If this is true, it may be assumed that the strain of *S. haematobium* in the Gambia and in Mauritius coincides there with its particular snail host (*B.* (*P.*)

*forskalii*), whereas in the Gold Coast this strain of the parasite is rare or absent.

It is evident that the greatest care must be taken before any bulinid species can be removed from the list of vectors, and at Accra attempts are continuing to be made to infect *B.* (*P.*) *forskalii* with *S. haematobium* derived from many different districts, including that of Tongu. To date, however, there is no direct evidence that *B.* (*P.*) *forskalii* can transmit the parasites in the Gold Coast.

I am grateful to the Chief Medical Officer, Gold Coast, for permission to publish these observations.

## Unilateral Hybridization

Species hybrids have been reported in *Petunia*[1] and *Lycopersicum*[2] which can only be made in one direction, namely, when the self-fertile species of the pair is used as female parent and the self-incompatible one as male[3]. This phenomenon, which may be called 'unilateral hybridization', also occurs with some species of *Antirrhinum*.

The *Antirrhinum* species have been classified[4] into four groups:

(1) Antirrhinastrum
(2) Orientalis
(3) Orontium } $2n = 16$
(4) Asarina $2n = 18$

In the Antirrhinastrum group, which includes most of the species, all the species are either self-incompatible, or have a history of self-incompatibility. The second group, Orientalis, which is represented by *A. siculum*, and the third which only includes *A. orontium*, are both self-fertile. The fourth group, containing only *A. asarina*, is also self-fertile; but this has a different chromosome number and has never been shown to hybridize with any other species. Six species from the Antirrhinastrum group have been crossed reciprocally with *A. siculum* and *A. orontium* and pollen tube growth observed.

From the results in Table 1, it will be seen that the pollen tubes of the self-fertile *A. orontium* and *A. siculum* species are greatly inhibited in the styles of the self-incompatible Antirrhinastrum species. By contrast, in the reciprocal crosses, when the self-fertile is the female parent, the pollen tubes grow right through the style and in two cases produce viable seed.

The flowers of *A. orontium* and *A. siculum* are much smaller than the self-incompatible species, and *A. orontium* is practically cleistogamous. *A. majus*, a species from the self-incompatible Antirrhinastrum group, needs special mention because intensive cultivation has selected self-fertile mutants with large flowers; but the intrinsic self-incompatibility of both its style and pollen is apparent from the interspecif crosses. Its style rejects the pollen of the self-ferti *A. orontium*, and its pollen grows normally in a the self-incompatible species.

Table 1

| ♂ | ♀ *A. siculum* | ♀ *A. orontium* | ♂ *A. siculum* | ♂ *A. orontium* | ♀ |
|---|---|---|---|---|---|
| Antirrhinastrum | | | | | |
| *A. majus* | ● | + | − | − | *A. majus* |
| *A. ramosissimum* | + | + | − | − | *A. ramosissimum* |
| *A. linkianum* | + | + | − | − | *A. linkianum* |
| *A. meonanthum* | + | ● | − | − | *A. meonanthum* |
| *A. glutinosum* | + | + | − | − | *A. glutinosum* |
| *A. molle* | + | + | − | − | *A. molle* |
| *A. siculum* | ⊕ | + | ● | + | *A. siculum* |
| *A. orontium* | + | ⊕ | + | ⊕ | *A. orontium* |

−, Pollen tubes greatly inhibited.
+, Pollen tubes grow through style.
⊕, Viable seed produced.

The *A. orontium* × *A. meonanthum* hybrid ($S_F$ $S_I$) which in appearance is nearly identical with tl mother parent, is sterile due to failure of chromosom pairing at meiosis. $S_I$ pollen from *A. meonanthu* can grow through the hybrid styles, but pollen fro $S_F$ *A. orontium* is inhibited. This is similar to tl behaviour of the *Lycopersicum esculentum* × *peruvianum* hybrid[2]. In the *Antirrhinum* allotetr ploid, chromosome pairing is restored and 16 b valents are found; but the plant is self-incompatibl The allotetraploid produces $S_{FI}$ pollen and this inhibited in $S_{FFII}$ styles. This could be due to eith the self-incompatibility alleles from *menonanthum* st functioning in the allotetraploid's genetic backgroun and/or the inhibition of *orontium*'s self-fertility alle by the self-incompatibility allele of *meonanthu* both alleles being present in the pollen grains an styles of the allotetraploid.

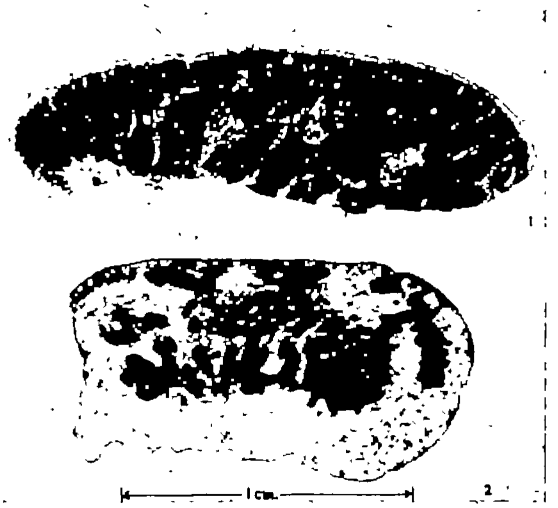
## Reproductive Organs of Foetal and Juvenile Elephant Seals

Between 1953 and 1955, I was serving with th Falkland Islands' Dependencies Survey in Sout Georgia and material was collected from the souther elephant seal, *Mirounga leonina*. Histological an histochemical examinations are being made of part of the reproductive tracts and various endocrin organs from foetal, juvenile and adult seals. Materi fixed in acetone for fourteen months and kept withi a few degrees of freezing point is still giving stron alkaline phosphatase reactions.

A hypertrophy of the gonads of the elephant se occurs in foetal life, similar to, but less marked tha that observed by Amoroso, Harrison, Matthews an Rowlands[1] and Harrison, Matthews and Roberts[2] the common seal, *Phoca vitulina*, the grey se *Halichoerus grypus* and various antarctic species.



(1) Section of ovary of fœtal elephant seal, about ten days ante-partum. (2) Section of ovary of elephant seal 29 days old. Both sections stained to show localization of alkaline phosphatase (black). The scale represents 1 cm.

The ovaries of a full-term fœtus, 142 cm. in length, eighed 6 gm. each; an ovary from a 2-day pup eighed 4·5 gm.; the right ovary of a 29-day pup eighed 3 gm. The ovaries of a yearling elephant al weigh 5·5 and 6 gm. each. In the adult, the verage weight (six measurements) of the ovary not ontaining either a corpus luteum or a ripe follicle nearly 7 gm. Thus the ovary of the full-term etus is nearly as large as the inactive ovary of the ature animal.

Similar changes are apparent in the male gonad nd prostate. A full-term male fœtus had testes eighing 18 gm. and 18·5 gm., and the prostate weighed 5·5 gm.; in a neonatal specimen the testes weighed 0·5 gm. each and the prostate 20·5 gm.; in a -day pup the right testis weighed 17 gm. and the rostate 13 gm.; in a 2–3-week old pup the testes eighed 15·5 gm. and 15 gm. and the prostate 2·5 gm. The adult gonad weighs about 500–600 m. and the prostate 300–600 gm.

A reduction in the size of the infantile adrenals akes place in the first few days after parturition. he adrenals of a full-term female fœtus weighed ·5 and 12·5 gm.; those of a 2-day pup, 9 gm. and ·5 gm.; of a 14-day pup, 4 gm. and 4 gm.; of a 9-day pup, 5 gm. and 6·5 gm. The adrenals of a earling cow weighed 7·5 gm. and 10 gm. and those f an adult cow (not pregnant or lactating) 7 gm. nd 7·5 gm. In the male, the fœtal adrenals weighed 2·5 gm. and 14 gm.; at 7 days, 8 gm. and 7 gm.; t two to three weeks, 6·5 gm. and 8 gm. The drenals of an adult male weighed 41·5 gm. and 1 gm.

In the full-term fœtal ovary, the main bulk of he gland is composed of interstitial tissue surrounded y a narrow fibrous tunic about 150–200μ across nd containing scattered young follicles. The inter-titial cells show great phosphatase activity, but the ortical region is practically free from phosphatase. he follicles are generally free from phosphatase, ut occasional ones show slight activity; these are elieved to be atretic. Subcortical crypt formation slight compared to that observed by Harrison and Matthews[3] in other seals. Ovaries from older seals how a decline in the amount of interstitial tissue nd a reduction in phosphatase activity. In a three-week ovary the interstitial cells are separated by fibrous tissue into small islets. At this stage healthy Graafian follicles have all but disappeared, though a number of primary follicles are to be found.

The testis of a full-term elephant seal is surrounded by a tunic 1·0–1·2 mm. in thickness. The gland is composed almost entirely of closely packed convoluted tubules. These are between 50 and 60μ in diameter and have no lumina. The interstitial tissue is very scanty and the individual cells are small. The development of this tissue is not nearly as marked as in the common and grey seals[2]. Testes of 7-day and 21-day pups present a not dissimilar picture, the rapid involution in the female gonad not being nearly as marked in the male.

The prostate of the full-term fœtus shows considerable activity. Most of the tubules have irregular lumina and contain inclusions, in some cases cellular debris. In the 21-day old specimen the tubules are smaller, the lumina have become more nearly circular in section and the amount of connective tissue has increased greatly so that it forms the bulk of the gland. The tubules are either empty or contain a little eosinophilic substance, not found in younger specimens.

In the epididymis of the full-term fœtus the tubules are about 150μ in diameter with a columnar epithelium 20–30μ in height. In the 21-day old epididymis the tubules are reduced in size; the epithelium is only about 10μ in height and the tubules contain a number of cells in their lumina.

## Plant Growth on 'Fly Ash'

In a communication outlining research on plant growth on 'fly ash' published in *Nature* of August 20, p. 352, by Rees and Sidrak[1], the following statement was made: "but as yet no attempt seems to have been made to examine its plant nutrient properties as compared with those of a normal soil". Work on various aspects of reclamation of land covered with 'fly ash' is, however, in progress at Leeds under a grant made available for the purpose by the Central Electricity Authority.

The investigations are following two main lines: (*a*) field-plot experiments designed to test the effect on plant growth of using soil coverings of various depths, together with incremental fertilizer dressings, upon 'fly ash' settling ponds; various crop plants are used in the experiments; (*b*) pot, and afterwards plot, experiments investigating the possibility of rendering the 'fly ash' in itself a medium suitable for plant growth.

Under the second heading possible methods of ameliorating the toxic properties of the material are being tried out, along with the effects of adding combinations of plant nutrients in standard factorial experiments. The work at Birmingham reported by

Dr. Rees has provided valuable information for this work. While it would be premature to report the result of the experiments, it can be stated that confirmation of the presence of manganese and aluminium toxicity has been obtained at Leeds.

A matter of general interest is that the manganese and aluminium toxicities found in the 'fly ash' are associated with high alkalinity, namely, $p$H 8·5 and higher in the Leeds samples. Manganese and aluminium toxicities in Britain are usually part of the 'toxicity-deficiency' complex of acid soils. There are reports of aluminium toxicity from some of the alkali soils of the United States, however[2]. Preliminary results in pot-experiments suggest that reduction of the $p$H by various means has a considerable effect upon these toxicities and can lead to increased plant growth.

## A New Imino-Acid in some Liliaceae

LINKO and I[1] isolated, last autumn, from *Polygonatum officinale* (and also from *Convallaria majalis*), a new imino-acid which on acid hydrolysis gave mostly homoserine. The elementary composition of the new compound corresponded to the formula $(C_4H_7O_2N)_n$ and had $[\alpha]^{20}_D$ − 118·4° (in water). The compound had all its carboxyl groups free and contained no primary but only secondary amino-groups. Because the compound contained no double bonds, it must have a cyclic structure. A 4-membered ring containing an imino-group and a free carboxyl group linked to the ring could have satisfied the formula, but using the method of Wendt[2] a molecular weight of approximately 300 was found, which is three times as high as that calculated for the simple molecule (six determinations in concentrations of 0·63–2·22 per cent in a non-polar solvent, the lactam of 4-amino-*cyclo*-hexane-carboxylic acid; calculated for $(C_4H_7O_2N)_3$, 303·3). On the basis of the molecular weight found, the compound seemed not to contain a simple 4-membered ring, even if all other known facts suggested this structure, but a corresponding ring three times as large and with three imino-groups in a ring to which three free carboxyl groups were linked. There was no other possibility of explaining the high molecular weight.

Fowden[3] isolated recently the same compound from *Convallaria majalis* without knowing of our work. His results are in good agreement with ours, with one important difference. Using the method of Barger, he found a molecular weight of approximately 100 for the compound, which thus probably contained a 4-membered ring containing an imino-group, and also a free carboxyl group. He has confirmed this conception by comparing the isolated compound with synthetic azetidine-2-carboxylic acid.

There is no doubt about the identity of the compounds isolated by us and Fowden. The three-fold molecular weight found by us is apparently wrong. The method of Wendt gave a correct molecular weight for some dipeptides and amino-acids in control experiments, but seems for an unknown reason not be suitable in the present case.

## Use of a Computing Machine as a Mechanical Dictionary

THE method for locating 'words' in a 'dictionai
proposed by Booth in his recent communication[1] b
been standard practice for a long time in codi
edge-punched cards used for indexing scienti
literature and for many other purposes. Thus, if o
denotes a consecutive series of holes 1, 2, 4, 8, . .
any number may be represented by punching t
appropriate combination of holes with a ticket pun
so that they become slots communicating with t
edge of the card; for example, the number 6
would be indicated by slotting 2, 4, 32, 128, 51
To find a desired card, it is necessary to ask
'questions' if the numbers run up to $(2^N - 1)$;
practice, one inserts a knitting needle into each ho
in turn, rejecting or retaining (as appropriate) car
which remain hung up on the needle when the pa
is lifted from the table and shaken.

The system has another interesting property
that $(2^N - 1)$ cards can be sorted into perfect seri
order by only $N$ successive operations of one needl
Thus if there are up to 1,023 cards, the code w
consist of ten holes, denoted 1, 2, 4 . . . 512.
sort the cards, one inserts a needle in the hole
all cards which drop out of the pack when it is lift
are replaced behind it without disturbing their orde
This operation is repeated with the hole 2, the ord
of the cards being carefully preserved, and so
along the series. After the hole 256 has been dea
with, it will be found that the pack is in exa
numerical order; to sort the 1,023 cards require
only ten operations. It is a consequence of th
method of representation of the numbers that i
theory the economy of the method increases as th
number of cards become greater—even though in pra
tice the mechanics may become more difficult.
take the example of Booth's lecture demonstration[1],
set of cards, on each of which was written a sing
entry of the Concise Oxford Dictionary, could
arranged in alphabetical order in fourteen operation
and even the half-million entries in the thirteen
volume Oxford English Dictionary would need onl
nineteen operations.

At the cost of using a few more holes and a numb
of knitting needles simultaneously, a more rapi
'selecting' procedure is possible; with $n$ holes or
can code $_nC_{n/2}$ items (if $n$ is even) and select an
desired card in a single operation using $n/2$ knittin
needles simultaneously (for example, 924 items wit
a twelve-hole code using six needles: twenty-tw
holes and eleven needles for the Oxford Englis
Dictionary). On the other hand, serial sortin
becomes more complicated.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, November 21

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Reception of Band I and Band III Television rogrammes".

University College, London (in the Physiology Theatre, Gower reet, London, W.C.1), at 5.30 p.m.—Mr. J. W. Trevan, F.R.S.: The Pharmacology of Respiratory Regulation".*

Manchester Literary and Philosophical Society (in the eynolds Hall, College of Technology, Manchester), at 5.45 p.m.—r Edward Bullard, F.R.S.: "Structure of Ocean Basins" (Joule emorial Lecture).

Royal Society of Arts (at John Adam Street, Adelphi, London, .C.2), at 6 p.m.—Dr. A. H. Cook, F.R.S.: First of Three Cantor ctures on "The Science of Brewing". (Further Lectures on Novemr 28 and December 5.)

Institute of Metal Finishing (at the Imperial College of Science d Technology, South Kensington, London, S.W.7), at 6.15 p.m.—r. A. Mohan: "The Use of the Electron-Microscope in Electroemical Research", Mr. D. I. C. Kapp: "The Application of Techical Studies to Industrial Experience"; Mr. D. M. Gilbey: "The inetics of Electrodeposition of Metals".

Pharmaceutical Society (at 17 Bloomsbury Square, London, .C.1), at 7.30 p.m.—Mr. F. Atkins: "Some Pharmaceutical Aspects Modern Cosmetics".

Royal Geographical Society (at 1 Kensington Gore, London, W.7), at 8.30 p.m.—Mlle. Ella Maillart: "Along the Malabar oast".

## Tuesday, November 22

Arthur Stanley Eddington Memorial Trust (at the Examina- on Schools, Oxford), at 5.15 p.m.—Prof. R. B. Braithwaite: "An mpiricist's View of the Nature of Religious Belief" (Ninth Eddington emorial Lecture).

University of London (at Bedford College, Regent's Park, ondon, N.W.1), at 5.15 p.m.—Prof. N. Millott: "Studies on Tropical chinoderms and Primitive Light Perception".*

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, eppel Street, London, W.C.1), at 5.30 p.m.—Dr. R. D. Harkness: Metabolism of Collagen". (Eighth of fifteen Lectures on "The cientific Basis of Medicine".)*

Illuminating Engineering Society (at the Lighting Service ureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. T. Catten: Ship Lighting".

Institution of Electrical Engineers, London Graduates and tudents Section (at Savoy Place, London, W.C.2), at 6.30 p.m.—r. D. H. Mullinger: "Electrical Measurement of Mechanical Vibra- ions".

Royal Aeronautical Society (at 4 Hamilton Place, London, .1), at 7 p.m.—Mr. Charles Gardner: "Aviation Journalism".

## Tuesday, November 22—Wednesday, November 23

Institution of Gas Engineers (at Church House, Westminster, ondon, S.W.1)—21st Autumn Research Meeting.

## Tuesday, November 22—Friday, November 25

International Congress on Documentation of Applied hemistry (at the Institut Français du Royaume-Uni, Queensberry lace, London, S.W.7).

## Wednesday, November 23

Textile Institute (at the Walker Art Gallery, Liverpool)—onference on "Raw Cotton: Its Properties and Distribution".

University of London (at the Postgraduate Medical School of ondon, Ducane Road, London, W.12), at 2 p.m.—Dr. P. Bishop: Endocrinological Investigations". (Further Lecture on Novemr 30.)*

Royal Society of Arts (at John Adam Street, Adelphi, London, .C.2), at 2.30 p.m.—Dr. B. K. Blount: "Research in Industry" E. Frankland Armstrong Memorial Lecture).

Institution of Post Office Electrical Engineers (in the onference Room, 4th Floor, Waterloo Bridge House, London, S.E.1), t 5 p.m.—Mr. L. S. Hughes: "English in the Engineering Depart- ent".

Institute of Fuel (at the Institution of Civil Engineers, Great eorge Street, London, S.W.1), at 5.30 p.m.—Mr. C. J. Stairmand: Modern Industrial Dust Collection".*

Society of Chemical Industry, Food Group (at the Chemical ociety, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—r. W. G. Wearmouth: "The Production of Processed Cheese in rance and Switzerland"; Mr. A. G. Sansome: "Airborne Con- amination of Foodstuffs by Rodent Hairs".

British Association of Chemists, London Section (at the Well- ome Institute, 183, Euston Road, London, N.W.1), at 7 p.m.—Dr. Gorringe: "Applications of Photography in Research and ndustry".

## Thursday, November 24

Institute of Refrigeration (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. L. Cowley: "Problems Connected with the Cooling of the Human Body by Means of Mechanical Refrigeration".

## Friday, November 25

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Winds in the Upper Atmosphere (including Drift and Irregularities in the F-Layer)". Chairman: Mr. J. A. Ratcliffe, F.R.S.

Royal Meteorological Society (in the Conference Hall, County Hall, London, S.E.1), at 5.30 p.m.—Mr. P. J. Meade: "Fog and Atmospheric Pollution" (Lecture open to sixth-form scholars).

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre, Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. A. R. Flint: "An Analysis of the Behaviour of Riveted Joints in Aluminium Alloy Ships' Plating".

Institute of Physics, Non-Destructive Testing Group (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Discussion on "Outstanding Problems in Industrial Radiology". Opening Speakers: Mr. R. Halmshaw and Dr. L. Mullins.

University of London (at Royal Holloway College, Englefield Green, Surrey), at 8.15 p.m.—Prof. P. M. S. Blackett, F.R.S.: "The Peaceful Uses of Atomic Energy".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. B. F. J. Schonland, F.R.S.: "Lightning and the Long Electric Spark".

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with an honours degree and teaching, industrial or research experience) in Chemistry, at the Rutherford College of Technology, to teach to H.N.C. and A.R.I.C. level—The Director of Education, Northumberland Road, Newcastle-upon-Tyne 1 (November 26).

Metallurgist (with a recognized metallurgical qualification and with sound experience, preferably in the electricity supply or associated industry) for the Chief Engineer's Department, Central Electricity Authority, London, to guide the branch on all metallurgical problems, co-ordinate metallurgical work in the various Divisions, and represent the Authority at technical meetings—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting AB/691 (November 29).

Lecturer (with an honours degree in zoology, and preferably special knowledge of agricultural entomology, and with research and teaching experience) in Agricultural Entomology—The Secretary, School of Agriculture, Downing Street, Cambridge (November 30).

Lecturer (graduate in science or medicine with postgraduate experience in some branch of physiology) in Physiology—The Assistant Registrar, Medical School, Birmingham 15 (November 30).

Senior Physicist (with a university degree in science, preferably with honours, with physics as the major subject, and considerable experience of applied research in physics), to be responsible for the planning and execution of research and related work in physics—The Director, Institute for Industrial Research and Standards, Glasnevin House, Ballymun Road, Dublin (November 30).

Assistant Lecturer, Grade B (with an honours degree in physics and preferably with some teaching and/or industrial experience) in the Department of Mathematics and Physics—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (December 1).

Lecturer in Geography—The Secretary of University Court, The University, Glasgow (December 1).

Research Assistant (with an honours degree in physics) for work in connexion with the study of the upper atmosphere by means of rockets—Prof. D. R. Bates, F.R.S., The Queen's University, Belfast (December 1).

Soil Physicist (graduate in physics or chemistry) at the Sabi Valley Experiment Station, to investigate the behaviour of soil and water under irrigation and water requirements of crops—The Secretary, Government of the Federation of Rhodesia and Nyasaland, Rhodesia House, 429 Strand, London, W.C.2 (December 3).

Assistant Lecturer in Mathematics (Pure or Applied)—The Principal, Royal Holloway College, Englefield Green, Surrey (December 5).

Lecturer in Mathematics—The Secretary of the Appointments Committee of the Faculty of Mathematics, The Arts School, Bene't Street, Cambridge (December 8).

Lecturer (preferably with experience with internal combustion engines or gas turbines) in Mechanical Engineering, at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 10).

Lecturer (graduate in science with special qualifications in botany or agricultural botany) in Botany—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (December 12)

Research Fellow in Animal Ecology—The Registrar, University of Adelaide, Adelaide, South Australia (December 15).

Lecturer in History and Philosophy of Science in the Department of History and Methods of Science, University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 16).

Lecturer (with good academic qualifications and practical experience, and with particular interest in developing improved methods of teaching engineering drawing and design) in the Department of Mechanical Engineering—The Registrar, The University, Bristol 8 (December 20).

Chair of Organic Chemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 14).

Biochemist to investigate biochemical pathways in the development of cellular damage by ionizing radiations—Dr. L. H. Gray, Director, British Empire Cancer Campaign Research Unit in Radiobiology, Mount Vernon Hospital, Northwood, Middlesex.

Economic Assistant (with at least a second-class honours degree in economics or similar subject, preferably with a mathematical or statistical background; one or two years postgraduate experience of economics work and an interest in science an advantage), with the United Kingdom Atomic Energy Authority, London, for duties including work on the economic aspects of nuclear power and on the general co-ordination of the nuclear power programme—Room 22, United Kingdom Atomic Energy Authority, 14 Ormond Yard, St. James's, London, S.W.1.

Industrial Chemist (with an honours degree in chemistry or Member of the Institution of Chemical Engineers, and at least ten years experience as a chemist in industry) in the Department of Heavy Industries, Eastern Region, Nigeria, to advise on the design of a laboratory and afterwards direct its work, to undertake research into local raw materials, organic and inorganic, and their potential utilization either alone or in combination with imported materials—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.461/411/02.

Physicist (with an honours degree in physics) in the Clinical Physics Department—The Administrative Officer, Christie Hospital and Holt Radium Institute, Manchester 20.

Plant Breeder (with at least a second-class honours degree and experience in plant breeding) at the West African Maize Rust Research Unit, Nigeria, to carry out research into maize breeding with special reference to resistance to pests and diseases—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.197/376/01.

Research Engineer (with an honours degree in engineering and one or two years practical experience) at the Research and Development Division of the Cement and Concrete Association, Slough, for work on concrete materials and methods of construction—The Secretary, Cement and Concrete Association, 52 Grosvenor Gardens, London, S.W.1.

Senior Geneticist (with at least a second-class honours degree in botany or other natural science, with some years experience of plant breeding and genetics and preferably acquainted with tropical perennial crops, particularly oil-palm or coconut-palm and maize breeding; cytological experience especially valuable) as Head of the Plant Breeding Division, West African Institute for Oil Palm Research, Nigeria, to plan and execute the research programme of the division, which is directed towards improving the oil-palm by selection and breeding, and includes investigation of the genetics and cytology of the crop—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.197/199/08.

Senior Scientific or Scientific Officers (with a first- or second-class honours degree in mathematics, physics or engineering, or equivalent qualification, preferably with experience in aeronautical research or development work in aircraft industry) at the London Headquarters, Ministry of Supply, for co-ordination of aerodynamic research at Research Establishments, and of research projects at aircraft firms—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.396/5A.

Soil Scientist (Analyst) (with at least a second-class honours degree in chemistry with one or two years postgraduate experience) in the Western Region, Nigeria, to carry out soil analyses and nutritional studies of cocoa and annual crops as a member of a team engaged in the systematic classification, mapping and characterization of soils and studies of their fertility—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.63/410/015.

Theoretical Nuclear Physicist (with a first-class honours degree in mathematics or physics and several years postgraduate research experience in nuclear physics), to carry out fundamental research in nuclear physics, particularly on the theory of nuclear structure, and to advise on the best values of nuclear constants to use in numerical calculations and on the design and interpretation of nuclear physics experiments—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 799/2.

# REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

## Great Britain and Ireland

The Registrar General's Statistical Review of England and Wales for the two years 1950–1951—Supplement on Hospital In-Patient Statistics. Pp. iv+151. (London: H.M. Stationery Office, 1955.) 7s. 6d. net. [228

Aero Research Technical Notes. Bulletin No. 150: Modern Production Techniques with "Aerolite" K, KL and R. Pp. 5. (Duxford: Aero Research Limited, 1955.) [228

*The Dogs' Champion.* Vol. 1, No. 1 (July, 1955). Pp. 2. (London Canine League Defence Fund, 1955.) Free to Supporters. [228

Anti-Locust Bulletin 20: The Vegetation of the Outbreak Areas of the Red Locust (*Nomadacris septemfasciata* Serv.) in Tanganyika and Northern Rhodesia. By D. F. Vesey-Fitzgerald. Pp. ii+31+8 plates. (London: Anti-Locust Research Centre, c/o British Museum (Natural History), 1955.) 3s. 6d. [228

*Automation Age.* Vol. 1, No. 1 (August, 1955). Pp. 6. (London: United Trade Press, Ltd., 1955.) Annual subscription 10s.; Single issues 1s. [248

Regulations for the Electrical Equipment of Buildings. Thirteenth edition. Pp. viii+182. (London: Institution of Electrical Engineers, 1955.) Paper 6s.; Cloth 8s. 6d. [296

Amateur Entomologists' Society. Leaflet No. 27: A Study of Insects Living on the Wayfaring Tree. By K. C. Side. Pp. 20. (L don: Amateur Entomologists' Society, 1955.) 1s. 6d. [

The Atom: Servant of Man. Pp. 13. (London: United Sta Information Service, 1955.) [

Modern Apparatus for Sterilization: an Address given to an Ev ing Meeting of the Pharmaceutical Society of Great Britain in Ed burgh on February 16, 1955. By J. H. Bowie. (Reprinted from *Pharmaceutical Journal*, June 11 and 18, 1955.) Pp. 24. (Londo The Pharmaceutical Press, 1955.) 2s. 6d. [

## Other Countries

Museum of Comparative Zoology at Harvard College. Brevio No. 45 (June 13, 1955): *Palaeotaricha Oligocenica*, New Genus a Species, an Oligocene Salamander from Oregon. By Richard V Frank. Pp. 12+3 plates. No. 46 (June 24, 1955): Cave-Fossil Ver brates from Camaguey, Cuba. By Karl F. Koopman and Rodo Ruibal. Pp. 8. (Cambridge, Mass.: Museum of Comparative Zool at Harvard College, 1955.) [2

Publications of the Kapteyn Astronomical Laboratory, Groning. No. 56: Proper Motions of Stars in the Selected Areas at the Equa derived from Plates taken at the Algar Observatory. By P. J. V Rhijn and L. Plaut. Pp. ii+100. (Groningen: Kapteyn Astronomi Laboratory, 1955.) [2

Universidad Nacional de Tucuman: Facultad de Ciencias Exac y Tecnologia. Revista. Serie A: Matematica y Fisica Teorica. V 10, Nos. 1 y 2: Resultados Generales Referentes a la Descripcion de Foton en un Medio Material, Por A. Battig. Pp. 111–136. (Tucuma Universidad Nacional de Tucuman, 1954.) [2

East African Meteorological Department, Memoirs. Vol. 3, No. Report on Experiments on Artificial Control of Rainfall at Ambo Kenya and Dodoma, Tanganyika, 1953–54. By D. A. Davies, Dr. H. Sansom and G. Singh Rana. Pp. 21. (Nairobi: East African Meteo logical Department, 1955.) Sh. 4. [2

Report of the Fourth Meeting of the FAO Working Party on Me terranean Pasture and Fodder Development, held in Lisbon, Portug 6–16 May, 1955. (Meeting Report No. 1955/12.) Pp. 49. (Rom Food and Agriculture Organization of the United Nations, 1955.) [2

Provincia de Mocambique. Servicos de Industria e Geologia. Se de Geologia e Minas—Memorias e Communicacoes. Boletim No. 1 Estudos Geoquimicos das Aguas Superficiais e Subterraneas d Rochas Sedimentares do Sul do Save. Por Dr. Vero Louis Bosa Pp. 44+3 plates. (Lourenco Marques: Artes Graficas, Lda., 1955.) [2

Education and Race Relations in South Africa. By Dr. T. B. Dav (Eleventh Hoernlé Memorial Lecture.) Pp. iii+31. (Johannesbur South African Institute of Race Relations, 1955.) [2

Suomen Geodeettisen Laitoksen Julkaisuja. Veröffentlichungen d Finnischen Geodätischen Institutes. Nr. 46: Professori Weikko Heiskaselle hänen 60-vuotispäivänsä omistettu juhlajulkaisu. (Public tion dedicated to Weikko A. Heiskanen on the occasion of his 60 anniversary.) Pp. 214. No. 47: Bemerkungen zur Methode d Basismessung mit Hilfe der Lichtinterferenz. Von Y. Väisälä. Pp. 1 (Helsinki: Suomen Geodeettisen Laitoksen Julkaisuja, 1955.) [2

Bulletin der Schweizerischen Gesellschaft für Anthropologie u Ethnologie 1954/55. (31. Jahrgand.) Schriftleitung: Dr. Otto Schle inhaufen. Pp. iii+5 plates. (Zürich: Société Suisse d'Anthropolog 1955.) 7.50 Swiss francs. [2

Uganda Protectorate. Annual Report of the Geological Surv Department for the year ended 31st December, 1954. Pp. ii+3 (Entebbe: Geological Survey, 1955.) Shs. 1/75. [2

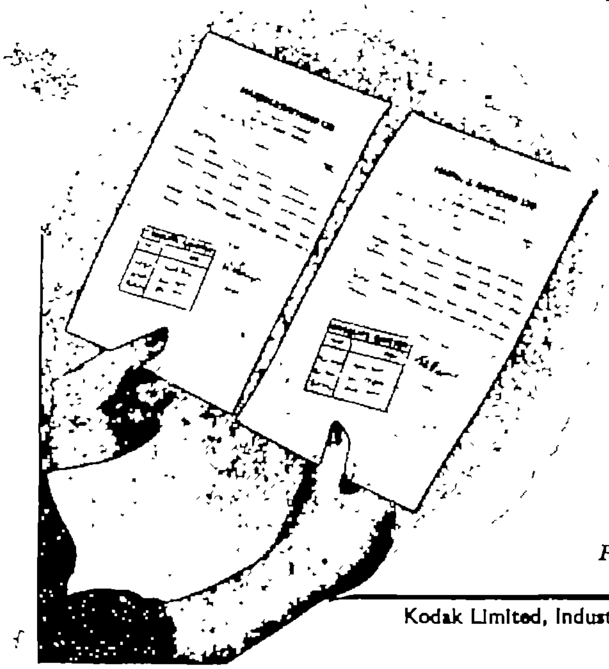
# *Cut copying time*

## with this 'one-step' paper



You copy documents with greater speed when you use Kodak 'Autopositive' Paper, because it gives you black-on-white photo-copies in one step, without intermediate negatives.

'Autopositive' paper's low-speed emulsion enables it to be processed in ordinary office lighting or indirect daylight. It has the high contrast and the "whiter white" base that are features of most 'Kodak' document-copying papers. You can make clear copies every time —even when the originals are faded.

**Kodak**

**'AUTOPOSITIVE' PAPER**

*Please write (mentioning 'Nature') for the booklet "Document Copying Papers" and a free wallet of specimen prints.*

Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W.C.2

*The names 'Kodak' and 'Autopositive' are trade marks and can properly be applied only to products made by Kodak Limited.*

### *MODEL 26*

## LABORATORY VALVE VOLTMETER

A precision instrument intended for research work and as a laboratory standard. It measures d.c. and a.c. voltages from 0.2 to 250 v. with an upper frequency limit of 200 Mc/s. It measures resistances from a few hundred ohms up to 500 megohms and power level variations over a wide range of decibels. Multipliers for 1,000 v and 2,500 v d.c. and a.c. are available. Each meter is individually calibrated so as to enable full advantage to be taken of the accuracy of the instrument which on all d.c. and low frequency a.c. ranges conforms to B.S.S. 89: 1954 for industrial moving coil meters.

# THE SPIRIT OF SERVICE AND THE WELFARE STATE

NDIVIDUALISM," wrote Lord Keynes, "if it can be purged of its defects and its abuses, is the t safeguard of personal liberty in the sense that, npared with any other system, it greatly widens field for the exercise of personal choice. It is o the best safeguard of the variety of life, which erges precisely from this extended field of personal oice and the loss of which is the greatest of all the ses of the homogeneous or totalitarian state. For variety preserves the traditions which embody most secure and successful choices of former erations; it colours the present with the diversiation of its fancy; and being the handmaid of periment as well as of tradition and of fancy, is the most powerful instrument to better the ure."

Lady Morris has set out in her book, "Voluntary ganisations and Social Progress"*, to examine the t played in social progress in Britain by the luntary bodies. The book is less detailed than rd Beveridge's survey, "Voluntary Action", and e misses the vivid vignettes with which, in his apter on pioneers', Lord Beveridge displays the ilanthropic motive in action; nevertheless, Lady orris sometimes probes further back into history, for ample, when discussing political movements; and touching on education and the churches, she deals th aspects Lord Beveridge largely ignores. Apart m occasionally bringing a closer and more personal uch into the discussion of particular problems than rd Beveridge did, the seven years that have passed ce Lord Beveridge's book was published enable dy Morris to testify more emphatically to the ntinuing value of the voluntary association in the cial Welfare State.

Her book, in fact, is essentially an exposition of e thesis Lord Keynes enunciated in the words ready quoted, and passage after passage in Lady orris's book recall those words to mind. In ilanthropy, in politics, in associations of working en in education, in the churches and in voluntary cial service, she traces progress to the vision and termination of individual men and women, sometimes as lonely pioneers, but generally as leaders and embers of groups, who were prepared to accept sponsibility and to devote time and energy to hieving social progress by means of democratic sociations outside the machinery of government. lieving that a society in which each person has the portunity of leading the good life can only be hieved if the proper spheres of action of State and dividual are discovered and respected, she is not ntent to display the past and the present, but oceeds to ask the leading questions which determine e realization of such a society.

What are the proper spheres of action for State d individual if such a society is to be possible? es the division of function now being evolved in itain conduce to the good life? And, if it is true, as Lady Morris's book, like Lord Beveridge's report, indicates, that social progress in the past has been largely due to the activities of individuals and groups outside the organization of government, what will happen if the parts played by statutory and voluntary action continue to change in the way in which they appear to be doing now? These are the questions that should be under examination, and although Lady Morris does not discuss them in any detail, at least in her introduction and in the second part of her survey of voluntary social service in the twentieth century, she indicates where the answers are to be sought. She also notes some of the factors that require further study, and directions in which our ideas should turn in considering the structure of society and the needs to be met by State action and those which should be left to the action of the individual or the voluntary group independent of statutory authority.

By and large, these questions are not being publicly discussed in the way their importance demands. Particular issues in which they are involved are apt to be determined in the light of partisan debate or the *ad hoc* circumstances rather than with regard to the long-term effects and their bearing on the intrinsic health of a democratic society. The warning notes sounded so clearly by Lord Beveridge as to the need to keep room, opportunity and encouragement for voluntary action in seeking new ways of social advance, for command of resources for social purposes being in the hands of some body other than the Government or the State, or, again, the need to make and keep something other than the pursuit of gain as the dominant force in society, have largely been ignored. Little has yet been done to influence directly in this way, not a few leaders, but the mass of the people; and democracy has still to show that, in discarding the inequalities, it can learn the virtues, of aristocracy.

For that reason alone, however much the present book by Lady Morris overlaps Lord Beveridge's report, the appearance of a fresh statement of the vital importance of voluntary effort, free to experiment, and endowed with the material resources which make effective service possible, would be welcome. Her book, however, bears the stamp of her own personality, and the arguments with which she challenges fresh thought on these vital issues are no re-statement but flow freely from the fountain of her own experience. Her story of the part voluntary groups have played in building the Britain of to-day, and in the achievement of reform and the elimination of injustice, is told in a way which shows clearly not merely that the opportunities for such voluntary effort persist into the welfare State, but also that without the help of such voluntary groups the individual and society will be the poorer, and even the security of the State endangered.

The survival of a society which provides its members with the opportunity to lead the good life depends, writes Lady Morris, "on there being enough people in it who understand what is at stake, who mind what happens to it, and who are prepared to take action in its service, not only by defending it in war but by striving in war and in peace for social progress". The work will, however, only be done successfully if the voluntary bodies continually re-examine their position, to see what aims and methods are demanded by actual needs and conditions; and Lady Morris pointedly directs this remark at the political parties and the trade union and co-operative movements, no less than at those engaged in social service in the more limited sense. All kinds of voluntary bodies need to adjust themselves continually to changing conditions if they are to render effective service and avoid setting up disruptive strains in the society in which they exist; and one of the great needs of to-day is not simply for self-examination of their functions and purpose by the voluntary bodies, but also for keen, unprejudiced thinking as to the limits of State action and the respective functions of voluntary and State effort.

---

* "Voluntary Organisations and Social Progress". By Lady Morris. . 224. (London: Victor Gollancz, Ltd., 1955.) 18s. net.

There is, however, a second need, and perhaps an even graver danger. What is achieved in Great Britain through the voluntary bodies depends on there being enough people able and willing to give them the necessary time and energy. This is recognized by Lady Morris, and she rightly emphasizes that public spirit and the desire to work with a group for a chosen cause have persisted into the welfare State with at least some recognition that without personal effort that State may atrophy.

Women are now playing a much greater part in voluntary service and organization. In spite of home ties, married women have, during the past twenty-five years, come to the fore. It is, perhaps, significant in this connexion that the author of "Voluntary Organisations and Social Progress" is a woman. Another outstanding living example of a woman voluntary worker is Lady Petrie, wife of the historian, who is not only a member of the London County Council and councillor (and, at present, mayor) of a London borough, but has also become known far beyond the boundaries of her borough as an effective voluntary worker especially in such fields as hospital organization, public health, education, care of the aged, maternity and child welfare. It is certain, therefore, that though half a century ago we looked to the leisured classes for voluntary work, this is not the case to-day; yet all have more leisure at their disposal.

The voluntary services have, it is true, a problem in learning to use part-time help on an increasing scale; but the major problem is in cultivating the spirit of service among the new leisured thousands—a spirit which runs counter to the whole climate of the Welfare State as often expounded in political doctrine. They are faced, however, with an even graver problem. Lord Beveridge himself emphasized the vital importance of voluntary action being dependent on current giving rather than on endowments from the past or favours from the State, and emphasized the need for exploring new channels for the impulse of giving among the mass of the people. He asked, in writing of our need for a never-ending line of successors to the Webbs: "By what device will the society of the future be able to ensure that the spiritual success of the Webbs will have their material resources research, untrammelled by other duties, by orthodo or by prescription of topics ?"

The point was put equally forcefully by Ro Wilson in the notes on the future of voluntary soc work included among the "Evidence for Volunte Action"; though, referring to the drying-up traditional sources of money, he expresses t opinion that of the three problems—the use of t part-time volunteer in official administration, t finding of money, and the finding of time—t finding of time is the most important. What nee to be emphasized, however, is that the problem money for voluntary work, and equally that of tin is largely the resultant of Government policy. T difficulties to which Lord Beveridge and Lady Mor direct attention are not the result of blind forces b to some extent are due to factors within our o control.

This is a matter for the scientist who is concerned to the future of the independent research institutio whether engaged in the physical, the biological the social sciences, with the resources available f such institutions and with the autonomy of t universities in view of their increasing dependence State support (and Lady Morris in her chapter education glances in passing at the independence the universities and at the future of adult educatio He may also turn to the challenging article *Lloyds' Bank Review* of October, in which Prof. Robbins asks some pertinent questions as to whe the present taxation policy of Britain is leading Prof. Robbins's "Notes on Public Finance" ran over a wide field, but their general interest, as w as their interest for the scientist, is derived not fro the discussion of the detailed effects of the Briti system of taxing, but from the searching inquiry in the long-term effects of financial policy and the fra advocacy of its use to promote changes in the structu of society that are desirable. Prof. Robbins maintai that the operation of the present tax structure not neutral, but that year by year it is pushing relentlessly towards collectivism and property-le uniformity.

We are not here concerned with the details of Pr Robbins's argument, or with the instances he choos to illustrate it. Its relevance in the context of t future of voluntary effort, and of the independe institutions where the creative thought and inqui upon which social and scientific advance alike depe can proceed unrestrained, is that he directs attenti to a political formative factor in our society which not being used as it might be. If, for example, o ideal is a property-owning democracy, we are allowi our tax system to work the other way; nor are using it to facilitate the solution to many social a industrial problems which might be possible instead of profit-sharing we used tax policy encourage industry to make its workers equi owners on a large scale.

What is important is that preconceived ideas a challenged, and an attitude to the death duties a to the present tax on marriage advocated which listic and related to the kind of State desired, her than to particular political doctrines or short- m Treasury dictates. Here, as in our attitude to e future of voluntary action, we are faced with a allenge to thought. If we really wish to build the od society, to safeguard the institutions which pro- le the growing-points and starting-points of creative vance in whatever field, we are taken back to is imperative and inescapable duty of re-examining, d where necessary re-shaping, the institutions hich at present minister to our needs, so that they rve our purposes more effectively in the conditions to-day. We need to be clear as to what those urposes are, and we need to be sure, as Prof. obbins reminds us, that we are not allowing factors der our control, by neglect or default, to carry us rther from our goal. Lady Morris's book and Prof. obbins's notes on public finance have this in mmon, that they challenge us to such examination d to constructive thought. They can equally mind us of Lord Beveridge's words: "Emphasis duty rather than assertion of rights presents itself -day as the condition on which alone humanity can sume the progress in civilization which has been terrupted by two world wars and which remains alted by their consequences". Much has happened the seven years since Lord Beveridge wrote those ords to attest their truth; and if Lady Morris's ook may be expected to engage more particularly e attention of professional associations of scientists, rof. Robbins's article will at least remind them that en fiscal policy can be such as to foster rather than discourage initiative, enterprise and the free inter- urse of minds and exchange of ideas, which are the ot of creative activity and the advancement of nowledge in every field.

## HE PERSONALITY OF A GENIUS

### arwin Revalued

y Sir Arthur Keith. Pp. x+294+5 plates. London: C. A. Watts and Co., Ltd., 1955.) 25s. net.

THE title of this book by the late Sir Arthur Keith is, perhaps, something of a misnomer. e does not attempt any major revaluation of arwin's scientific work but, rather, is concerned in he main with Darwin the man, with the events and mpo of his life and his habits of mind and body. gain it is not so much a revaluation of these hat we are offered, but rather a condensation of the normous mass of data which Darwin left behind im in the form of letters and other writings. Few ves are better documented; the very richness of he sources makes it a laborious task to extract out f them a fair and complete view. Sir Arthur writes: I have tried as far as possible to make Darwin tell he story of his life in his own words, while I am erely playing the part of a 'cinema-operator' ".

I think most readers will agree that this endeavour as been very successful. But what an astonishing nd complex character Darwin was, and how difficult o form a just picture of him! Towering above verything else is his majestic grandeur as a scientist nd as a thinker who changed the whole of man's iew of his position in the universe. But at the same time his weaknesses as a human being are very obvious. He remained a devoted parent, and a kindly and helpful colleague to his scientific contemporaries; but throughout most of his life, his devotion to natural history reached a pitch which can only be called obsessional. For the rest, he cut himself off from most social contacts, and from almost the whole non-scientific area of human interest—poetry, art, politics and, to a large extent, religion. Or perhaps one should say he was cut off, by a chronic digestive illness against which the only effective remedy seems to have been work, but which often left him too incapacitated even for that. It is Darwin, the pillar of Victorian achievement, rather than Proust, the recorder of Victorian society in decay, who is really the example of the invalid genius, whose intellectual life was passed on a sofa. But for all that, he possessed in full measure another solid Victorian virtue—he was an excellent man of business and managed his investments (largely in railways) so that at his death he left a very sizable fortune.

How did this character—physically tortured, one must suppose, by some psychosomatic trouble, and retaining an unruffled intellectual assurance at the expense of extreme concentration on observing the external world—grow out of the relatively straightforward and energetic young man we meet in the "Voyage of the Beagle", with his enjoyment of a dinner of freshly killed beef grilled at the campfire of the Gauchos on the Argentinian pampas? And what influence, if any, did the peculiar forces which must have been buried in Darwin's odd personality exert on his scientific theories, which, it must not be forgotten, carried with them consequences of the most profound importance for our philosophies both of society and of the individual? Sir Arthur Keith does not attempt to answer such questions, although he allows himself a few asides which touch on them. But he stage-manages the appearance before us of a historical personage of great magnitude and complexity, whose personality undoubtedly deserves much fuller study and discussion than has yet been given to it.

C. H. WADDINGTON

## WEATHER OF THE TROPICS

### Tropical Meteorology

By Herbert Riehl. Pp. x+392. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 61s.

IT is not a little odd that text-books on general meteorology rarely make much reference to tropical meteorology (the hurricane or typhoon may be a notable exception) and even provide rather little in the way of theory which may be usefully applied to the weather and winds of tropical regions. Yet the tropics embrace almost a half of the earth's surface, contain a large number of its people, and have weather which differs notably in style from that of extra-tropical regions. The Second World War, with important theatres of operation in lower latitudes, brought home to many our humiliating ignorance of tropical meteorology and spurred some to a considerable effort of research on the subject. Accepting, for the moment, a purely utilitarian point of view, it is clearly to our interests to further the work then started; for it is within the tropics that solar energy is most freely available—if we can make effective use of it—and, not unrelated, that the most substantial increase in world crops could occur. That the tropics or, rather, the sub-tropics (±30° latitude), which form the more natural meteorological boundaries, contain both the driest and wettest latitudes of the world is not the least part of the practical challenge, and this can scarcely be met until we can describe and understand more fully than at present the atmospheric processes within those latitudes. The problems are much more than those of geography, though geography is inevitably involved.

Tropical meteorology suggests to many, I suppose, trade winds and monsoons, the former blowing with great and, in an earlier day, useful regularity, though with seasonal variations, and the latter with well-defined onset and appropriate precipitation in their season. The picture is not wholly false; but the great irregularity of the incidence and amount of rainfall in both systems, day to day, and year by year, indicates that the weather is not to be explained wholly or even largely in terms of climate. In other words, it is the variations about the climatic norm as well as the norm itself which demand inquiry in low as in temperate latitudes. Moreover, since the temperate and high latitudes rely ultimately for their winds and rain on a source of energy within the tropics, we must suppose that variations in the tropics are somehow reflected in extra-tropical weather and climate.

Prof. Herbert Riehl was one of the war-time workers who was impressed by the variability in tropical weather and who has made substantial contributions to its study. He has now written a book which, while giving due weight to the geography and climate, is most concerned to present a physically co-ordinated account of the whole sequence of weather in low latitudes. His book is thus descriptive and theoretical, but only partly deductive; more description and more theory are required before a satisfactory deductive treatment will be possible. The skill with which he has combined description with theory is masterly, so that reading is a great joy as well as a good discipline.

There are twelve chapters, in which spatial and temporal variations in pressure, wind, temperature and rainfall are first presented and discussed, the accent being on climate. Due regard is paid to vertical variation where appropriate, for although upper-air stations are still woefully sparse in the tropics, the War and subsequent years have added considerably to knowledge of conditions aloft. Diurnal and orographic effects are treated next, and then follows a most successful chapter on convection. Its terms extend well beyond the tropics and should be read by any interested in this field; its relevance to the book is, however, unquestionable, since convection is so important a part of the motion of the tropical atmosphere. A rather irrelevant chapter on the physics of tropical rain is then interpolated from another hand, and the remainder of the book (six chapters) is devoted to synoptic disturbances and the general circulation. The treatment is unquestionably successful, both in description and in making the reader aware of how much may be explained on dynamical and thermodynamical grounds and of how much for the moment may not. The author's own researches on waves in the Easterlies guarantee successful treatment of that subject, and I found the chapter on hurricanes particularly cogent writing.

The book is so successful on the whole that one major criticism, related to the author's treatment of hydrodynamical problems, will not be misconstru While the book is addressed to a graduate in phys the author has decided to avoid mathemati equations as far as possible—but not complete This leads him to talk of unfamiliar concepts such vorticity without the introductory formal treatm which shows how they arise in meteorological hyd dynamics, and to proceed in a few lines to a math matical statement of the theorem of conservation potential vorticity without allowing the reader know quite how he got there. It is doubtful wheth a subject like hydrodynamics, which is certain difficult of simple exposition, and yet so importa for the author's purposes, is to be apprehended such methods—or by such 'wilful' remarks as "t current meets the *opposition* of the low-level ma time air" (my italics). Again, the author's int pretation of differential equations, in the intere presumably of simplicity, has a touch of eccentrici here and there and is likely to confuse more th clarify.

But this will prove to be an important book in t development of meteorology and is greatly to welcomed. It is well produced, well referenced a well indexed, and the misprints, though rath numerous, are not serious. Its price is rath forbidding to most individuals who might hope buy it from a sterling purse. P. A. SHEPPARD

# LETHAL FACTORS IN GENETICS

## Letalfaktoren

In ihrer Bedeutung für Erbpathologie und Ge physiologie der Entwicklung. Von Prof. Ern Hadorn. Pp. 388. (Stuttgart: Georg Thieme Verla 1955.) 39 D. marks.

LETHAL genes or chromosome rearrangemen with lethal action are not essentially differen from other genes or chromosome rearrangement All genes and many chromosome rearrangemen affect development, and whether this results in dea before reproduction depends equally on the gen themselves as on the organization and living co ditions of the individual in which they occur. study of the action of lethal genes can therefo scarcely avoid dealing with questions of general ge physiology. In the present book, as shown by i subtitle, this aspect has been emphasized, and t result is a most valuable contribution to gener developmental genetics.

The larger, and by far the most important, part the book uses lethals for illustrating and analysi general principles of gene action. The example range far and wide through the realm of livin beings from bacteria to man, although the emphas is on higher animals. Much of the material come from the impressive work of Prof. Ernst Hador himself and his school. The chapter on the bio chemical analysis of lethal development deals wit a new and promising field in which the author ha done pioneer work. Among the discussions of wide questions, three seem particularly interesting to me The first deals with the value of phenocopy studie as tools for elucidating gene action. Prof. Hadorn' attitude is here mainly one of caution; he thinks i unlikely that these studies will shed much light o primary gene effects. The second concerns th specificity of gene action. In contrast to Grüneberg author admits the possibility of true organ cificity caused by gene action on a field of differ- iation or on the integrative processes which precede an formation. The third is pleiotropy, of which penetrating analysis is presented. Primary pleio- py, that is, the existence of multifunctional genes, considered as a possibility. Other types of intra- lular or intercellular reaction chains that may lead pleiotropism are illustrated diagrammatically. For e of these, namely, the selective activation of genes the cytoplasm, Beale's work on *Paramecium* anti- ns might have been quoted as evidence. The minology of pleiotropic mechanisms matches the btlety of this analysis, and it leaves me wondering ether a simpler, though less precise, terminology ght not be preferable? Some new terms, such as tophene' and 'allophene' for phenotypic traits at are determined respectively by the genes in the ected cells themselves or by genes in other cells, e useful and merit a place in the vocabulary of velopmental genetics. For readers who are timidated by the abundance of technical terms, a ll glossary is provided.

The first third of the book treats more purely netical questions, such as the detection of lethals, utation-rates, and the frequency of chromosome arrangements with lethal effect. These lucidly itten chapters, although less stimulating and iginal than those dealing with gene action, should very useful for the beginner in mutation work.

The clear writing and logical presentation make e work easy to follow and pleasant to read. It has en beautifully produced, and the paper does justice the many excellent diagrams, most of them drawn the author's son, which form a specially attractive ature. There is an extensive list of references. ltogether, this is an admirable book, interesting and imulating for the experienced geneticist and yet mple and clear enough for a newcomer to the field genetical research. One minor mistake may be rrected in the next edition: the hormone therapy gainst teleangiectasia, mentioned on p. 286, is used heterozygotes, not on homozygotes which, as plained on p. 138, are probably inviable.

C. AUERBACH

# THEORETICAL ORGANIC CHEMISTRY

heoretical Principles of Organic Chemistry
y Prof. Walter Huckel. Vol. 1. (Translated from e corrected seventh German edition by Prof. F. H. athmann.) Pp. xi+904. (Amsterdam: Elsevier ublishing Company; London: Cleaver-Hume Press, td., 1955.) 77*s.* 6*d.*

THIS English version of Prof. Walter Hückel's text-book, which has been given a clear, if pparently at times rather literal, translation by Prof. . H. Rathmann, will be of interest to all organic emists. The topics considered in this first volume, fter a preliminary chapter on valency, include ereochemistry, oxonium compounds and molecular mplexes, compounds with abnormal valencies, utomerism, intramolecular rearrangements, steric arrangements, unsaturated compounds, aromatic mpounds, and the course of chemical reactions. he material is dealt with largely in chronological rder, from the point of view of the problems which arise directly from classical studies of organic reactions. Those aspects which require considerable knowledge of physical chemistry—particularly the relationships between constitution, physical properties and reaction velocities—have been deferred to the second volume.

Modern theories of organic chemistry derive some of their attraction from their power to enable, first, the correlation, within a consistent theoretical framework, of many of the at first sight diverse phenomena of organic chemistry, and secondly, the recognition of recurring patterns of behaviour, even though these may not always be quantitatively predictable. Not only do these theories rely on physical principles in discussing molecular properties and reactivities, but also they allow an extensive correlation of the physical properties of atoms and molecules with their chemical structures and reactivities. The impact on chemical theory of the ideas derivable from atomic and molecular spectroscopy, for example, has been very great, and the overlapping, in this kind of way, of pure chemistry, on one hand, and pure physics, on the other, is a striking and particularly happy feature of modern chemical thought.

The method adopted by Hückel suffers from the disadvantage that a considerable separation is made of the organic from the physical approach to the subject. Although the author himself has obviously such a thorough understanding of both aspects that he finds it necessary frequently to make references forward to more complete discussions which presumably will appear in Vol. 2, the result is still not entirely satisfactory.

Even within the adopted framework, considerable criticism is possible, particularly of the treatment of recent work. Many of the more significant advances of the past twenty years have been neglected, or are mentioned only in footnotes. The treatment of the Walden inversion is but one example of a limited recognition of recent advances. The rule is given that "the replacement of negative groups by anions gives a Walden inversion"; but it is stated that otherwise "for the greater portion of the yet known reaction processes, the riddle of the Walden inversion is not yet solved". Many would have considered that this was a conservative point of view even in 1938, when E. D. Hughes (*Trans. Farad. Soc.*, **34**, 213) discussed, in the course of a general survey of the Walden inversion, the effects of substituents in determining the steric course of unimolecular nucleophilic substitutions. To retain this attitude to-day, without even a passing reference to the development, by S. Winstein and his school as well as by British and by other American workers, of the stereochemical effects of substituents *beta-* to centres at which nucleophilic displacements occur, renders the whole discussion of this important aspect of aliphatic chemistry completely out of date.

Few authors, perhaps, succeed in putting the theoretical developments of their subject into completely proper historical perspective. As a source of references to the relevant experimental and theoretical contributions from the German schools of chemistry, this work is probably unexcelled. As a discussion of the phenomena of organic chemistry, and of the deductions which can logically be derived therefrom, it should be of some value to those prepared critically to compare this treatment with that preferred in other works. As a modern discussion of theoretical organic chemistry, it is disappointing.

P. B. D. DE LA MARE

### An Introduction to the Theory of Seismology

By Prof. K. E. Bullen. Second edition. Pp. xv+296. (Cambridge: At the University Press, 1953.) 35*s*. net.

THE first edition of Prof. K. E. Bullen's "Theoretical Seismology" was so clearly and concisely written that within a short time it had become the accepted standard treatise on the subject. The only substantial point of criticism of that edition was the absence of references; evidently with the idea of brevity. This defect has been remedied in the second edition, which concludes with twenty pages of references to treatises and original papers, classified under chapters, or sections of chapters, instead of the more usual kind of reference to a specific sentence or phrase in the text. Actually, this method has the advantage of serving both as a list of references (with the name of the author of a paper as a sufficient connecting link) and as a bibliography for each subdivision of the subject.

The second edition follows the pagination of the first, but sentences and short paragraphs have been inserted which bring the book up to date. As examples mention may be made of the application by F. Birch of Murnaghan's theory of finite strain, and B. Gutenberg's discussions of Californian earthquakes (which have suggested the idea of 'low-velocity layers'). Prof. Bullen might well have enlarged on his own recent contributions to the theory of the structure of the Earth's interior; in fact, however, he does little more than mention his 'Model *B*', in which the coefficient of incompressibility is taken as a smooth function of the pressure $p$ below the region *C*—that is, below about 1,000 km. An account is given of W. H. Ramsey's theory of phase transitions, in which the Earth and the terrestrial planets are assumed to have the same primitive chemical composition, with phase changes induced by pressure. Bullen has shown that the use of his Model *B* gives a closer fit with the data than does his Model *A*, as used by Ramsey.

Other additions are an account of the recent work of Jeffreys on the thicknesses of the continental layers, and a brief statement of Willmore's discussion of the observations made on the Heligoland explosion. The author is to be congratulated on the freedom from misprints and on the maintenance of the standard of conciseness despite the development of the subject.

R. STONELEY

### Plant Climate and Irrigation

Edited by Sidney A. Searle. Pp. xi+155. (Chichester: Chichester Press, Ltd., 1954.) 20*s*.

THE title of this book is misleading; it suggests a work on the relation of plant growth to regional climates and the application of irrigation principles to all kinds of crops. In fact, the book refers almost exclusively to glasshouse crops and mainly to tomatoes.

As so often happens with symposia, the contributions by the different authors are very unequal in quality and value. Scientifically, the most valuable contribution is the chapter reviewing the measurement of soil moisture, since, apart from the contributor's own more extensive review published elsewhere, this information has not previously been collated. A large section of the book is a reprint of a thesis submitted for a higher degree and is, *ipso facto*, unsuitable for publication, in spite of the useful work described. Elsewhere there are some bad errors in plant physiology and a number of theories be on slender evidence. A chapter entitled "Growin a Microclimate" turns out to be an *ex parte* argum in favour of a particular system of heating for gl houses. In passing, it may be remarked that i difficult to imagine how plants in a glasshouse wo be considered as growing in anything other tha "microclimate"—a much overworked word at present time.

The book is intended for the commercial grow but in the reviewer's opinion it might well be n understood by such a reader if he were not scienti ally trained and could sift the grain from the ch

R. H. STOUGHTO

### Freshwater Microscopy

By W. J. Garnett. Pp. xii+300+50 plat (London: Constable and Co., Ltd., 1953.) 30*s*. n

THIS book is intended as a simple introducti to the microscopical study of the plants a animals of the fresh waters of Great Britain. It written in a popular style and the author no dou had the amateur microscopist mainly in mind wh writing it; but it could be used also by students biology at schools and universities. It can recommended to anyone taking up this branch study. Not very many species are dealt with, b the distinguishing characters of the selected orga isms are given clearly, so that it should be possil to achieve at any rate an approximate identificati of many of the common microscopic organisms fresh water. Recognition will be greatly helped the numerous photomicrographs, most of which very characteristic of the living specimens.

The author makes quite a number of mistakes matters of fact (as well as in spelling); but ma who could easily correct the slips could not wr nearly such a good book as this. It is obvious th the author has first-hand acquaintance with subject and a lively interest in it, and he writes wi infectious enthusiasm. He is essentially an observ of the living organism and its activities. T practical advice is on the whole good, though o regrets that he does not mention the valuab mounting media introduced by Amann.

JOHN R. BAKER

### Cells and Societies

By Prof. John Tyler Bonner. Pp. iv+234+ plates. (Princeton, N.J.: Princeton Universi Press; London: Oxford University Press, 195 25*s*. net.

IN this lucid and entertaining exposition, t author's central theme is that in animals a plants at all the levels of development in the sca of evolution, including that of man himself, a certa recurrent sameness can be discerned, in particular such activities as the intake of food, reproductio and co-ordination; and this is demonstrably tr whether we make an analysis of life processes in a animal society or in an individual unicellular organis While the details of how these needs are met a endlessly varied in different groups and organism a scrutiny of the wide range of materials which t author discusses shows how general and pervasi are certain basic phenomena. Because of t simplicity and clarity of the exposition, and t effort that the author has made to formulate an discuss general ideas on life processes, this book ca be commended both to the interested lay reader an to the student of biology.

C. W. W.

# WEATHER FORECASTING: THE FUTURE OUTLOOK[*]

By Sir GRAHAM SUTTON, C.B.E., F.R.S.

Director of the Meteorological Office

THE profession of meteorology is concerned, among other things, with a branch of technology t is based upon the application of physical prin- les to an ancient and universal art. However, s article is confined to weather forecasting as actised by the professional meteorologist. In itain everyone forecasts the weather every day, if y as a conversational gambit, and the mass of verbial sayings, signs, saints' days and the like nected with the weather show the antiquity of e practice of observation and deduction. This ditional form of weather prediction is based on e belief that the state of the atmosphere in a ited region at any given instant is uniquely ated to the weather afterwards experienced in the ne region. Provided that the period of the fore- st is kept short, this belief is largely justified, and the days of sail the seaman, by watching the sky d the barometer, could often make reliable fore- sts of coming storms. Much the same degree of eather wisdom' is shown by those who live in the untry, in particular by shepherds and others whose rk keeps them in the open for long periods.

Traditional weather lore has no conscious relation th physics. A few of the best-known signs and rtents can be explained in terms of physical eteorology; but proverbial sayings are often tangled with superstition, and the majority, on se examination, have proved to be unreliable ides. This applies without exception to proverbs at attempt to forecast for long periods ahead. us the weather on St. Swithin's Day (July 15) ars no unique relation to rainfall during the next rty days, and I know of no popular belief that will lp me to predict the nature of, say, the coming nter with any degree of assurance.

Scientific weather forecasting is the child of the ctric telegraph. We can fix its date of birth in itain with fair precision, for in 1859 the British sociation, meeting in Aberdeen under the presi- ncy of Prince Albert, decided to recommend that e Board of Trade should instruct its newly formed eteorological Department to make use of telegraphy warn ports of approaching storms. To-day we uld not regard this as genuine forecasting, but ther as timely reporting. However, FitzRoy, the st director of the Meteorological Office, encouraged Le Verrier of France, soon began to include prog- stications in his warnings, and in 1861 he intro- ced the word 'forecast'. It is appropriate here repeat FitzRoy's words concerning forecasts: rophecies and predictions they are not': the term recast is strictly applicable to such an *opinion* as the result of a scientific combination and calcu- tion . . .". Soon after taking up my present post, was moved to write a letter to *The Times* in much e same vein, reminding the readers of that news- per that "the meteorologist is to be regarded more an adviser than as a prophet".

FitzRoy's experiment—for it was scarcely more an that—did not find universal approval among men of science. This is scarcely to be wondered at, because for many years the whole matter of foretelling weather had been bedevilled by the almanac makers. After FitzRoy's death in 1865 the Royal Society advised the Board of Trade to discontinue the publication of forecasts, but that "an endeavour should be made to improve the storm warnings, to define the principles on which they are issued and to test these principles by accurate observations". In other words, the investigation was to continue, but in private. This happy state of affairs (happy, that is, for the meteorologist) did not go on for very long. The public demand for forecasts, supported by the British Association, became so strong that the next ten years saw the re-introduction of the public statements of impending weather. Such forecasts have continued until the present day.

Early in the latter half of the nineteenth century (it is difficult to fix the date with greater precision), the Dutch meteorologist, Buys Ballot, recognized the relation between wind and the horizontal distribution of pressure. Buys Ballot's Law, as it is now called, states that in the northern hemisphere an observer with his back to the wind has low pressure on his left hand. (The rule is reversed in the southern hemisphere.) This directed attention to the use of isobaric charts, and it soon became evident that such charts, drawn for pressures reduced to mean sea-level, exhibited certain well-defined patterns that we now call depressions, anticyclones, troughs and ridges.

From the latter half of the nineteenth century until to-day, professional meteorology has been largely preoccupied with the study of the anatomy, life-history and movements of these patterns in the pressure field. The weather forecast is largely based upon the observed behaviour of the atmosphere in the vicinity of such disturbances, but this, of course, is not the whole story. Following Dr. R. C. Sutcliffe, we may consider that the pressure field as a whole comprises the following systems:

| Scale | Example |
|---|---|
| (*a*) Micrometeorological | Cloud elements; turbulence near a boundary. |
| (*b*) Sub-synoptic | Local showers, thunderstorms, local winds. |
| (*c*) Small synoptic | Small depressions and anticyclones, tropical tornadoes. |
| (*d*) Large synoptic | Semi-permanent continental anticyclones; long waves. |
| (*e*) General circulation of the atmosphere | |

The practice of operational forecasting involves only those features of the synoptic chart that are included in (*c*) and (*d*). In general, disturbances of the pressure field of scales (*a*) and (*b*) cannot be 'seen' on the chart; the resolving power of the meteorological network, even in a highly developed country like Britain, with many airfields, is far too low to allow more than a small fraction of all the showers and minor storms to be recorded. The disturbances that are indicated on the forecaster's chart have something of the character of external waves in that the shape of the stream-lines of the motion is not very different at different levels and the change of wind with height is approximately the same along all the verticals within a restricted region. It is thus possible to approximate to a typical atmospheric disturbance of the synoptic scale by a two-dimensional model, and much of the early work on dynamical meteorology was concerned with such models. The outstanding feature of such disturbances, however, is their slow translational motion. The typical depression of these latitudes moves across the country at a speed between 20 and 30 m.p.h., and it is important to recognize that other disturbances, such as sound waves and gravity waves, move far too rapidly and are of too small an amplitude to have any appreciable effect on weather.

---

[*] Substance of a Friday Evening Discourse given at the Royal stitution, London, on November 4.

We can get an idea of how the meteorologist of to-day works by considering two of the daily publications of the Meteorological Office. The first is the *Daily Weather Report* containing, on its inner pages, the familiar isobaric charts for the northern hemisphere and, on a larger scale, for the north-western corner of Europe. The pressure field depicted is that for a hypothetical mean sea-level surface—which may or may not coincide with the real surface of the globe. All observations, whether on high or low land, have been reduced by a mathematical formula to 'zero height'. This type of chart is too well known to need further description. The second publication, the *Daily Aerological Record*, is not so familiar. The inner pages of this publication contain two sets of maps, namely, contour charts of the 700-, 500- and 300-millibar pressure-levels and thickness charts for the strata between the 1,000-, 700-, 500- and 300-millibar pressure-levels. These terms need some explanation. A contour chart shows the height, in feet, of a surface of constant pressure above mean sea-level. This type of chart has largely replaced the constant-height chart for upper-air work for a variety of technical reasons that need not concern us here. The thickness chart shows the relative topography of the constant-pressure surfaces, and, by inverting the familiar barometric-height formula for an isothermal atmosphere, it is easily seen that the difference in height between two isobaric surfaces (that is, thickness) is proportional to the mean temperature of the stratum of air contained between them. In other words, thickness lines are isotherms of mean temperature, and instead of the customary 'lows' and 'highs' of pressure on a constant-height surface we now have 'cold' and 'warm' centres.

These considerations have important repercussions on the forecasting of winds at great heights, that is, for modern aviation forecasts. It was early realized in meteorology that the simplest possible relation between the pressure distribution and the wind is that given by the so-called geostrophic balance. Left to itself, any fluid tends to move from regions of high to regions of low pressure, but in non-equatorial latitudes the effect of the earth's rotation on the atmosphere is to be reckoned with as well. As a result, winds deviate and blow around centres of low and high pressure in the senses indicated by Buys Ballot's Law. If it be further assumed that the wind strength is automatically adjusted to achieve a balance between the pressure and deviational forces, the resulting motion is along the isobars. This motion, known as the geostrophic wind, is a good approximation to the actual wind at about 2,000 ft. above a level surface. The geostrophic wind can be found very easily, by means of a transparent scale, from the contour lines of any isobaric surface. The vector difference between the geostrophic winds on any two surfaces is called the thermal wind. The name is derived from the fact that this wind can be estima graphically, like the geostrophic wind, but now fr the thickness lines, or isotherms, with the therı wind blowing cyclonically around a 'cold' centre a anticyclonically around a 'warm' centre. One of most important facts about such centres is that tl play a large part in 'steering' the depressions a anticyclones.

Thus modern forecasting has a pronounced thr dimensional aspect. The information necessary the construction of the upper-air charts is obtair mainly by the radio sonde or its latest developme the radar sonde. In the radio sonde, pressure, te perature and humidity are transmitted back to ea as musical notes. Measurement of the pitch of th notes gives the value in its proper units of the ent being considered.

What is the future of forecasting ? Has there be any marked improvement in the accuracy of t published forecast in, say, the past twenty or thir years ? Neither of these questions is easily answer The phrase 'accuracy of forecasts' conceals one of t outstanding difficulties of meteorology, namely, th of evaluating the degree of success attained in objective fashion. The present situation is perha best summed up by saying that the basic questi for the ordinary person, "Will it rain to-morrow cannot be answered with markedly greater precisi to-day than it could twenty years ago. On the oth hand, the meteorologist now can answer ma questions, especially those relating to high-altitu flights, which he could scarcely have contemplat in the early 'thirties. There are three great proble confronting the forecaster : how to improve the fo cast of the general situation, that is, of the mov ments of disturbances that produce the da fluctuations of weather over the British Isles ; h to improve local forecasting, that is, forecasting f restricted regions for the next six, twelve or twent four hours ; and how to produce reliable long-ran forecasts, that is, forecasts of the general charact of the weather in, say, the coming month. There a of course, many other problems of comparab importance, but I will restrict my attention to thes

The problem of forecasting the broad features the pressure distribution over the British Isles a the surrounding seas for a period of twenty-four hou amounts to what is called professionally the produ tion of a 'prebaratic', or chart showing the distributi of pressure at the end of the prescribed period. present this is done by extrapolation. The forecast deduces the likely movements of the main distur ances by a combination of experience and physic reasoning. The process, naturally, is highly su jective and liable to be badly in error at times. this sense weather forecasting might be described more of a craft than a profession, since much of th skill is acquired by experience with older hands wh in the course of years, have developed a 'nose' f coming changes and often include a good deal intuition in their prognostications. Progress in th craft is now slow, if it exists at all. During rece years, however, the situation has undergone a radic change. It has long been a dream of meteorologis that some day it will be possible for their science approach the precision and infallibility of spheric astronomy; but the tremendous complexity of th meteorological problem and the relative paucity data have made a "Nautical Almanac" of the weath seem more improbable than interplanetary travel. notable attempt to produce a system of mathematic ecasting was made by the late Dr. L. F. Richardson his book "Weather Forecasting by Numerical ocess", published in 1922. The attempt was rtive in that the one example worked out by hardson (using inadequate data) was badly in or; but the principles used were novel and largely rect, and thus the seeds were sown. The develop- nt of the high-speed electronic computer in the ars following the Second World War, together with better understanding of the difficulties of the blem, have now made it possible to contemplate introduction of purely mathematical methods o operational forecasting. This has already been ne in the United States and in Sweden.

It is impossible, in this article, to go into the highly nplicated mathematics in any detail. Briefly, the thod is as follows. At any zero of time we may sider that the pressure and motion fields are own, approximately, for a series of levels over a le area of the northern hemisphere. The sub- uent changes in these fields are governed by the own laws of physics; but it is impossible to proceed ng the full exact equations, because they are too mplicated and also because there are insufficient ta and knowledge available to evaluate all the ms. Instead, certain simplified forms of the uations of motion are used to predict the changes the pressure patterns during the next twenty-four forty-eight hours. The mathematician, starting m a known distribution of pressure, uses the thod of step-by-step integration to produce the al pattern. Even with the very simple models ed, the work involves many millions of mathe- tical operations and could not be contemplated as realistic exercise without electronic aids. Modern chines, however, can complete the solution in less an one hour, and the total time taken to produce forecast chart is perhaps three or four hours.

In Great Britain the study is regarded as still in e research stage, and as yet no attempt has been ade to bring machines into operational use. The ults of trials with past charts are encouraging, and is remarkable that simple models have done so ll. The consensus of opinion, in Britain and else- here, seems to be that numerical forecasting offers e brightest hope seen for many years of sub- ntially improving routine weather forecasts. It is ssible that in the next decade or two the develop- ent of the method may result in the near elimination 'major errors' in the forecast of the movements of ge-scale disturbances. If this optimistic prophecy realized, scientific weather forecasting will have ade its greatest advance since its inception nearly hundred years ago.

It is important to realize that this approach, at esent, is restricted to prognostication of the pressure stribution with an indication of the broad features the vertical motion. The weather still has to be duced from the forecast chart by the human being ing time-honoured methods, that is, mainly by a udy of the geometry of the forecast pressure field. is is no easy task. Further, such studies relate ly to the macroscopic features of the pressure and otion fields and therefore concern only the general uation. Forecasts of local weather, where these volve prognosis of the fine structure of the field, are tside the scope of the mathematical study. Yet, early, it is very desirable to be able to time fairly curately the approach of a rain belt or a large understorm for a densely populated area like eater London.

It seems that the main hope for any improvement here lies, not in increasing the complexity of the synoptic chart, but in quick, accurate and frequent reporting. For this the meteorologist must be able to scan the atmosphere in his vicinity as well as to consult his chart, and here again he can now call on electronic aids. Within the past few months specially designed radar equipment has been installed on the roof of Victory House, Kingsway, London, for this purpose. The equipment works by the reflexion of 3-cm. waves from rain-drops, hailstones, snowflakes and particles of ice—the normal constituents of rain-producing clouds. An approaching storm of sufficient intensity can thus be seen as an echoing area on the cathode-ray tube, sometimes as much as a hundred and fifty miles away. But the radar method is selective in that it cannot 'see', for example, fog and mist. Aids such as this radar equipment, especially if suitably multiplied and coupled with a detailed study of the weather peculiarities of a restricted region, could lead to a much-improved service to the public.

Thus the 'further outlook' for short-range weather forecasting is not unpromising, and a judicious blend of the mathematical approach, with the continuing detailed study of the anatomy of weather systems, can be expected to yield good results in the not too distant future. But it is otherwise with the problem of long-range forecasting. Present methods of forecasting for twenty-four hours ahead have been extended to four-day periods, mainly by an intensive study of conditions in the upper layers of the atmosphere; but the degree of reliability decreases rapidly with the length of the period. In general, in temperate latitudes, there is usually no unique relation between the synoptic situation at any given time and that five days or more later. This illustrates what is perhaps the major difficulty in forecasting weather. Influences that were initially below the threshold of observation can grow and become dominant in a period as short as a few days, so that new initial conditions have to be introduced at frequent intervals. In this sense the problem of weather seems to be indeterminate, and a limit is imposed on the applicability of present methods of numerical forecasting which is unlikely to be removed by refinements in the mathematics. Even the most elaborate model is unlikely to produce trustworthy results from a single situation more than seventy-two hours ahead (except in certain highly stable situations, such as a well-developed summer anticyclone), and on many occasions the maximum period of validity may well be no more than forty-eight hours.

Despite many patient researches, particularly in Germany, there does not seem to be at present any real basis for reliable forecasts for periods of a month or more. Even less reliable are forecasts of the general nature of seasons, for example, whether the coming winter will be mild or severe. There is no well-defined rhythm in atmospheric processes (except for the cycle of the seasons) on which such forecasts can be founded. On the other hand, there are many tantalizing clues that there may be subsidiary rhythms, and this, no doubt, accounts for much of the assiduity with which investigations into long-range forecasting have been pursued. There is, for example, evidence to support a belief in the reality of singularities—periods of characteristic weather (such as dry, rainy or stormy)—that tend to occur about the same date in most years, but these are by no means infallible guides. They indicate, at the most, that not every variety of weather is equally probable on any given day in the year; but as yet there is no criterion for their appearance or non-appearance in any given year. Research into long-range forecasting has developed chiefly on two lines: the purely statistical approach, and the dynamical method. In the statistical approach, little or no attempt is made to assign physical causes, and the investigator usually confines his attention to a search for significant patterns or repetitions in the weather records. Harmonic analyses of temperature, for example, have been made for very long intervals; but the periods which emerge as 'significant' have not proved sufficiently persistent or of sufficiently large amplitude to form a basis for worth-while prediction. Nor is there any evidence to connect abnormalities in terrestrial weather with astronomical phenomena such as sunspots. The dynamical method has b developed mainly in the United States, wh monthly forecasts of departures from climatolog means are produced from a study of the lar pressure systems over the northern hemisphere. far the success obtained is marginal.

Progress in weather forecasting is like climbin peak in the Himalayas. It is not difficult to obt a moderate degree of accuracy, but the final stag that of reaching a high consistent level—is like c quering the last thousand feet on some hithe unclimbed peak. There is no easy way up, and p gress must be, at times, painfully slow. It is not e established beyond doubt that progress is certa but meteorologists have some reason, at least, believe that one day the goal will be in sight.

# THE LAST VOYAGE OF JOHN CABOT AND THE ROCK AT GRATES COVE*

By PROF. ARTHUR DAVIES

University of Exeter

IN 1497 John Cabot sailed from Bristol and discovered about three hundred leagues of the coastal regions and waters of North America. On his return he made a map of his discoveries, and the Spanish Ambassador in London sent a copy to Spain. From this the world map of Juan de la Cosa[1], drawn in 1500, was able to show an east–west coast of sea and land "discovered by the English" with English flags. It can be concluded that Cabot had discovered the Saint Lawrence region and that he had coasted back along south Newfoundland. He was awarded an annual pension of £20 by Henry VII.

In May 1498 John Cabot left Bristol in a fleet of five ships, provisioned for a year, which suggests they did not expect to be back until the spring of 1499. One ship put back to Bristol and reported that Cabot had sailed around the south of Ireland and set course north-west. No English documents record the route or discoveries made in this voyage of Cabot in 1498. His pension, due half-yearly, was paid to his wife on his account at Michaelmas 1498 and on March 25, 1499, but was not paid again. It would seem that he was assumed to be alive until March 25, 1499, but that news of his death was brought back to Bristol soon afterwards. John Cabot never again appeared in English records, and there is no trace of his death or burial in England. In 1939 Denys Hay[2] reported that in a manuscript of Polydore Vergil of about 1512, entitled "Anglica Historia", there is a reference to the death of John Cabot at sea. It reads as follows: "King Henry at the request of one John Cabot, a Venetian by birth and a most skilful mariner, ordered to be prepared one ship, complete with crew and weapons; this he handed over to the same John to go and search for those unknown islands. John set out in this same year and sailed first to Ireland. Then he set sail toward the west. In the end he is believed to have discovered no land [since he did not return, he was not credited with discovery of lands] save in the depth of the ocean, into which he is thought to have gone down together with his ship, being seized by the ocean itself, for after that voy he was never seen again".

Sebastian Cabot, the second son of John Cab transferred to Spanish service in 1512. By 1515 was describing an important voyage of discov which he claimed to have made for Henry VII England. By using the clearest indications from various versions of Sebastian, his voyage can described as follows. He set course around the so of Ireland and then north-west and so reached arctic ice sheet to the east of Greenland. Turn south-west, he rounded the south of Greenland a sailed on westward for about ten degrees of longitu between 61° and 64° N., in what is now Davis Str He met land and kept south and west of it in wl is now Hudson Strait. Here the crews threaten mutiny because of the cold and storms, and so June 11 he turned south and kept along Labrad east Newfoundland, Nova Scotia and New Engla In the latitude of about 38° N. he ended his d coveries and turned back to Europe. Sebast declared that at his farthest west, in Hudson Str at 62° N., he was as far west as Cuba and that t sea opened southward (probably Ungava Bay).

The geographical details of this voyage describ by Sebastian are so near to truth that they co not possibly have been invented; it is certain th such a voyage of discovery had been made. But is very unlikely that Sebastian Cabot had led such voyage. In one account he claimed to have ma this voyage in 1494, when he was only twelve ye of age, in another 1496, in others 1498 and, implication, in 1508–9. He was twenty-six years age in 1508, and this is the only possible acceptal date for him to have been given command of such voyage. But he took care not to mention his fathe voyages at all, and there is no hint in English reco of any such voyage with Sebastian aboard, still l that he was in command. In 1521 he was in Londo and Cardinal Wolsey urged the London merchants support a venture under Sebastian Cabot in sear of a north-west passage. They replied, without co tradiction from the Cardinal: "We think it were t a venture to joperd V shippes with men and ds unto the said Iland upon the singular trust of man, callyd as we understand, Sebastyan, whiche astyan, as we here say, was never in that land self, all if he makes reporte of many things as he heard his father and other men speke in times t”.

---

* Paper read at Bristol before Section E (Geography) of the British Association on September 6.

The majority of scholars have concluded that bastian lied, and that he claimed credit for the coveries made in the 1498 voyage of John Cabot. 1929 J. A. Williamson[2], a leading English authority the Cabots, accepted the claim by Sebastian that had made such a voyage of discovery, dating it 8–9. But the evidence of the early Portuguese and anish maps of America proves conclusively that such oyage of discovery had taken place before 1500, en Sebastian was less than eighteen years of age l could not conceivably have been in command.

The Portuguese map of Cantino, drawn in 1502, ows Greenland and the Labrador–Newfoundland gion as two utterly distinct and separate lands, ich had been discovered for King Manoel of rtugal. In 1500 Gaspar Corte Real discovered eenland, and in 1501 he coasted Labrador and east wfoundland as far west as Saint Mary's Bay. This yage did not pass westward into the Saint Lawrence gion, nor did it make any discoveries of land in va Scotia and New England. Moreover, it took ly a few months, May–October 11, 1501. At some ce, probably in east Newfoundland, fifty Indian isoners were taken[4], one of them being in possession a broken gilt sword of Italian origin (which points John Cabot), while an Indian boy was wearing ver earrings of Venetian origin (which points to ncius, the young son of John Cabot, about fourteen ars of age). The only voyage in these waters evious to that of Corte Real was the 1498 voyage John Cabot. These relics are mute witnesses that hn Cabot and Sancius either reached shore alive or at their bodies were washed ashore. Indian custom uld ensure that an Indian boy wore the earrings ly if they were found on the boy Sancius; otherse they would have been worn by a man.

All the major Portuguese maps of the period show eenland and Labrador–Newfoundland as two quite parate land masses, much to the east of their true sition to ensure they were within the Portuguese here as defined by the Treaty of Tordesillas. This s the official Portuguese concept of the lands of north-west Atlantic, based on the voyages of rte Real. They include the Caveri (Canerio) map, Hamy–King map, the anonymous Portuguese p, all of 1502, the Reinel–Pilestrina map of 1503, Waldseemuller map of 1507, and others. The me Terra Corte Real is given on most of them to brador–Newfoundland, and on some Greenland is med Terra Labrador, after a squire of the Azores o first reported its discovery to Henry VII of gland.

The map of the north-west Atlantic by Pedro inel is utterly different from these other Portuguese ps. Reinel, the greatest of the Portuguese cartoaphers, was a free lance and not employed by the own. He drew maps from any sources available to n, and this is one which shows virtually continuous ntinental land from east Greenland to New Engd. The unusual outlines of Greenland and the gion to the west of it are to be explained as the tting of the ship's track rather than the coasts, error probably by Reinel. It was originally dated 1499 by Schmelling; but the map is now assigned to 1502, prior to the other Portuguese maps, by Fontoura da Costa[5] and Armando Cortesao[6], the leading authorities on these maps. It is a Portuguese map with Portuguese names, and its latitudes are nearly correct throughout. It shows nearly continuous continental land from east of Greenland westward by way of Davis Strait, Hudson Strait, Labrador, Newfoundland to New England, ending at about 38° N. The two flags, of Portugal and Spain, indicate the dividing-line of the meridian of Tordesillas passing through west Newfoundland, utterly different from the official Portuguese maps based on the Corte Real voyages. This Reinel map of 1502 corresponds exactly with the discoveries claimed by Sebastian Cabot, thus proving that the voyage which made those discoveries had been completed before 1502. It rules out any possibility that Sebastian could have led it, for he was then less than twenty years of age.

But the map of Juan de la Cosa, drawn in 1500, also shows a continuous continental land mass extending from “the English coasts with flags” northward by way of Labrador and swinging north-east to include Greenland. The coasts are distorted and not comparable in detail with those of the 1502 Reinel map; but the cosmographical concept is identical and the main coastal trends similar. It shows that the voyage which revealed the North American lands from Greenland to New England preceded the Cosa map of 1500, and that it must have been the voyage of John Cabot in 1498. Cosa got the outlines of the 1497 Cabot voyage from the Spanish Ambassador in London. The general outline of the 1498–99 Cabot voyage, brought back by the surviving ship to Henry VII, may well have been copied roughly by the Spanish ambassador and sent to Spain, as had been done in 1497.

The nomenclature of the 1502 Reinel map on the Labrador and Newfoundland coasts is particularly rich, and it reveals numerous associations with the voyage of John Cabot. At 59° N. are the island of fortune and the island of torment. André Thevet[7] stated: “in that place the pilot of King Henry of England thought to have found a strait to pass into the Pacific Ocean. But being in the latitude of 59 degrees north . . . he came to touch at the island of Caravelle where he almost lost his life because of the breakers, rocks and perils that are there. Passing beyond he entered the river of torment.” Evidently he escaped disaster by good fortune, and fortune might have come to be the name of the island.

Then come C. domarco, san johan and san pedro, which are the Cape of Saint Mark and the Islands of Saint John and of Saint Peter. In one of the accounts of Ramusio, it was stated that Sebastian Cabot turned back on June 11, owing to threat of mutiny. The name Saint John is an indication that the island was found on, or near, the feast day of Saint John in the Roman Catholic Calendar of Saints. This was June 24, and Saint Peter was June 29, which dates correspond very well with a voyage which turned back at 62° N. in Hudson Strait on June 11. The feast of Saint Mark is April 25; this name occurs twice on this map, which indicates it was not given by reason of its dates but, as was often done, for personal reasons. John Cabot was a citizen of Venice and his patron saint was Saint Mark. When he first discovered land in 1497, he raised the banner of Saint George for England and of Saint Mark for Venice.

Y dos aves is Portuguese for island of birds; C. dos gamas is cape of deer; boaventura means good luck. Y. do frey luis at 51° N. is the island of brother Lewis or Luis. To-day it is Lewis Island, the English name, not the Portuguese. Most scholars have assumed this indicates the presence of a friar on board, but this is very improbable. Priests never went on dangerous voyages of exploration, only on later voyages of colonization and settlement. Columbus and Vespucci had no priests on their voyages of exploration. The eldest son of John Cabot was called Lewis, and he does not seem to have survived this voyage. The island of brother Lewis may have been named after him.

Baya de Santa Cyria indicates August 8. Y. dos bacalhaos is island of cod fish. Sebastian Cabot told Peter Martyr that he had given this name to east Newfoundland because of the plentiful supply of cod fish found there; but Martyr noted that there were many Spaniards who denied that Sebastian Cabot had sailed so far west and discovered this land. Baya do concepcam indicates the feast of the Conception on December 8, which points to a very long delay in this region. The next name, C. da espera, gives the explanation of this long delay, for it means the cape of waiting. To English ears espera sounds like spear, and Cape Spear occurs on modern maps just south of Saint John. It is possible that John Cabot took only two ships on this westward exploration, the other three ships which sailed out in company from Bristol being bound for Iceland. Thus there would be one consort ship, and it is probable that this ship set up a look-out post at C. da espera and then spent months searching the coasts and rivers to the south and then to the north for signs of survivors. This was the duty of a consort ship, and faithfully they pressed their fruitless search month after month. R. de sam francisco to the south is October 4, while baya do concepcam to the north is December 8. The tragedy would seem to have occurred as follows. After fishing for cod fish near the island of Bacalhaos (the modern Baccalieu island), they turned south to cross Conception Bay. Possibly during hours of darkness the ship of John Cabot "went down in the depth of the ocean being seized by the ocean itself". The description almost implies that it was not wrecked on a coast nor sunk by tempest. "Being seized by the ocean itself" suggests that the consort ship was at a loss to account for the disappearance of the Cabot ship. It is possible that the ship carrying John Cabot struck an iceberg during darkness not far from Baccalieu Island, at the north end of Conception Bay. Near by is Grates Point, and just west of it is Grates Cove. It may be that Cabot, his young son Sancius and some of the crew succeeded in reaching Grates Cove in the ship's boat. Cabot and Sancius certainly got ashore, alive or dead, for the broken Italian gilt sword points to Cabot himself and the Venetian silver earrings to the boy Sancius.

The consort ship must have missed them next day but, assuming they would link up, carried south as far as Cape Spear, when it became apparent something was seriously wrong. Thereafter the crew of the consort ship set up a look-out at this 'cape of waiting' and searched the coasts to the south, and then finally in December, as a last resort, they retraced their course northward and searched Conception Bay, naming it on December 8 after three months of vigil. They may have discovered wreckage of the ship, but most probably gave up the search in December, finding no trace of Cabot. The date, December 8, points clearly to the Cabot voyage of
1498, which did not return to Bristol until a
March 25, 1499. The Corte Real voyages were b
in Lisbon by early October on each occasion.

Resuming the voyage, the consort ship roun
C. Rase, which means 'flat cape'. English ears no
it as Cape Race, its modern name. The ship cros
the Saint Lawrence to Nova Scotia, and thereaf
coasted to New England in mid-winter. The Isla
of Saint Johan, off Nova Scotia, indicates the fe
of Saint John of Ravenna on January 12. Af
reaching 38° N. the consort ship turned back
England, where its Portuguese pilot, Juan Fernand
the labrador or squire of Terceira in the Azo
reported the discovery of Greenland, etc., to Ki
Henry of England and the loss of John Cabot w
the King's ship. This is noted from the account
Alonso de Santa Cruz, a friend of Sebastian Cabot
Spain, writing in 1541. In his work, "The Voya
of the Cabots" (1929), J. A. Williamson quotes
following passage of Alonso de Santa Cruz: "T
region of which we now wish to treat is commo
called the land of the Labrador (Greenland). .
As for the western side toward the land of
Bacalhaos it is said that two Portuguese brothe
named the Corte Reals, . . . asserted that the ma
land, of which they reached the extreme end,
separated from that island of the Labrador by a ve
large and wide sea channel, of which the pilot Anto
Gaboto also had information. It was called the isla
of the Labrador because a Labrador of the Azo
gave notice and information about it to the King
England, when he sent in search of it Antonio Gabo
the English pilot and father of Sebastian Gabo
. . . The land named the Bacalhaos, where the Co
Reals went to colonise, was first discovered by
pilot Antonio Gaboto, the Englishman, by comma
of the King of England". It may be noted, in passi
that Williamson argues that Santa Cruz was mistak
and knew little about the matter. But Santa C
had accompanied Sebastian Cabot on his voyage
the Plate River in 1526 and had close connexic
thereafter in Spain with him. It is probable th
Sebastian Cabot was the source of this account
Santa Cruz, belatedly giving credit to his father
the discovery of the Bacalhaos before the Corte Re
went there.

These documents and maps show that the 14
Cabot voyage discovered the continent of Nor
America from Greenland to Delaware Bay in 149
99. When Cabot went down with his ship,
Portuguese pilot, Juan Fernandez, completed
voyage and reported back to Henry of Englan
This report found its way through the Spani
Ambassador in London to the 1500 map of Juan
la Cosa in Spain. Fernandez's own chart of the voya
formed the source of the 1502 Reinel map of
north-west Atlantic. It is the only map record a
the only surviving document of the last voyage
John Cabot. It serves as a complete and accur
record of that voyage and its proud achievement
discovery in the New World. Since Fernandez he
his lands in Terceira under the Corte Reals, captai
donatory of the island, it is almost certain that
passed on information of the Cabot discoveries
them. The Corte Real voyages of 1500 and 15
were, therefore, the outcome of the Cabot voyag

An important piece of evidence in this reco
struction of Cabot's last days is the large rock
Grates Cove, near Grates Point, north of the hea
land which terminates Conception Bay and practi
ally opposite Baccalieu Island. This rock, which w

t described in 1822 by William Epps Cormack as
large block of rock which stands on the shore",
rs an inscription, still partly discernible, in which
words Jo Caboto can be plainly traced. Parts of
er names are legible, and among these are Sancius
l Sainmalia. Leo F. English, curator of the
seum at St. Johns, Newfoundland, has recently
nmented on this rock[8]; he quotes Archbishop
wley for the statement that Grates Cove comes
m the Italian gratia, thanks be to God. No
glish names can be deciphered.

n the supposition that John Cabot and Sancius
h some of the crew got ashore at Grates Cove, it
uld seem that, knowing the consort ship would
rch the coasts for them, they inscribed these names
the rock at Grates Cove. No one by the name of
nmalia is known to be connected with the expedi-
n. It may be that it is the illegible remnant of
nta Maria save us" or some such expression. It
not credible that such an inscription could be
thing but genuine, for no forger before 1822,
wever learned, knew of the Reinel 1502 map, which
s first discovered in 1844, and not until to-
y has anyone reconstructed the 1498 voyage of
n Cabot and suggested that his ship went down
the vicinity of Grates Cove. One can only assume that Cabot and his party, after inscribing the stone, were overcome and killed by the Beothuk Indians. The searchers from the consort ship never went north of Baccalieu Island and never saw the inscription on the rock. Had they done so, it is possible they might have saved John Cabot and his men, stranded on this wild coast to end their days.

The rock at Grates Cove, the broken gilt sword of Italian origin and the silver earrings of Venetian origin are relics of the disaster which overtook John Cabot. With the aid of Portuguese maps of America they help to reconstruct in detail the fortunes and achievements of the 1498–99 voyage, one of the greatest triumphs over hardship and danger that exists in the annals of American discovery.

# LABORATORY DESIGN

## SURVEY OF SPACE AND SERVICES REQUIREMENTS IN TWO AGRICULTURAL RESEARCH LABORATORIES

By R. LLEWELYN DAVIES and J. W. NIGHTINGALE
Division for Architectural Studies, Nuffield Foundation, London, N.W.1

AND

NORMAN T. J. BAILEY
Design and Analysis of Scientific Experiment, University of Oxford

N 1954, at the suggestion of the Agricultural
Research Council, the Division for Architectural
idies of the Nuffield Foundation began an investi-
ion into the design of laboratories. Work is at
sent in progress on several aspects of laboratory
ign, including the arrangement of rooms for con-
nient circulation, the layout of local and central
res, etc. The problems of laboratory lighting and
tilation, the economics of service installations and
performance of various materials and finishes are
subject of studies being conducted jointly with
Building Research Station. This article describes
ilot survey, made last year, which was designed
throw light on the provision of space and services
meet the needs of scientific workers in the labor-
ries of the Agricultural Research Service. The
vey is being followed by a main one, at present
progress, covering all the laboratories of the
ricultural Research Council and two or three
oratories operated by other authorities. Both
veys are concerned with the design of the common
e of laboratory, where work is done at benches;
y do not cover rooms designed for special purposes,
h as constant-temperature rooms, or the sort of
ommodation needed for large-scale work such as
ineering research. The results of these surveys
d the other studies at present in progress will be
ced before a panel of scientists for critical con-
eration.

When a laboratory is planned, decisions are required as to the provision of space and the supply of gas, hot and cold water, electricity, suction, compressed air, etc., for each worker. Successful design will depend on giving sufficient facilities without extravagance. Some authorities have established standards for space—generally expressed in floor area per worker—but these standards seemed to be arbitrary and to vary without apparent reason. Attempts have been made to throw light on these problems by measuring the floor area allotted in existing laboratories to scientific workers[1]; but this approach takes no account of the fact that the space provided may be too little or too great. Provision of services also varies considerably, and authorities differ widely on what they consider necessary.

It was therefore decided to carry out a survey of the use actually made of space and services by scientists working in reasonably well-provided laboratories; the pilot survey was undertaken to develop practical methods of collecting information and was carried out during April–June 1954 in two establishments—Rothamsted Experimental Station and the National Institute for Research in Dairying at Shinfield, near Reading. These stations were chosen because they cover a wide range of disciplines, and are reasonably well provided with space and services. The results obtained should not be taken as necessarily representative of institutions of the Agricultural Research Council, or of the needs of scientists throughout the year; but they show the sort of information which can be obtained by the method employed. The main survey, at present in progress, covers a wider range of institutions during a whole year.

The method adopted in the pilot survey was to observe selected individuals at work in the laboratory for a period of one hour each. The individuals, 232 in number, were selected from staff lists supplied by the stations and were grouped together according to grade—scientific officers, experimental officers, or assistants. In the pilot survey the total numbers were too small for significant differences to be distinguished in the needs of the several scientific disciplines. In the main survey the data should be sufficient to bring out these differences, if they occur.

In studies of this sort the presence of an observer may affect the activities of the person observed: to minimize this effect, visits were made in random order, and no individual knew in advance that he was going to be observed. Analysis of the data showed that there was no appreciable change in the pattern of work during the period of the study, and it therefore seems likely that the data collected were not greatly affected by the presence of the observer. Continuous observation for a period of an hour was of value in the pilot survey, as it enabled the observers to see scientific work as a process, and to notice points of general importance in the interpretation of the results. It was found that many of the observations repeated at short intervals during the hour were highly correlated, and accordingly the main survey has been designed to employ the 'snap-round' technique, so that observations on each individual are made at widely separated times.

## Bench-Length

The bench-length in use during the period of observation was recorded; where scientists had in use simultaneously two or more lengths of bench in different parts of the laboratory, all such lengths were added together.

Data from the pilot survey were analysed to show the proportion of time that workers in each of the three groups studied used particular lengths of bench. Differences in the lengths used by scientific and experimental officers were small; it was found for these grades that about 12 ft. of benching satisfied one man's requirements for 97 per cent of the time. The data also can be used to show what saving in space arises where a number of men work in the same laboratory; for example, three men working independently in the same laboratory would be satisfied for 97 per cent of the time by 23 ft. run of bench. Assistants were found to need rather more bench-length than scientific and experimental officers; while this result might be expected, it is worth noting that most standard scales of provision allow less space for assistants than for scientists. In practice, small teams often work together. Table 1 shows the bench-length that would be needed to satisfy the needs of a number of teams for varying percentages of time. A finding of some interest was that for 57 per cent of a scientist's time and 33 per cent of an assistant's time, no bench was in use at all.

A somewhat similar analysis can be made for the space occupied by sinks and draining boards, the main difference being that, though these are essential, they are very seldom used—only 1, 2½ and 4 per cent of the time for scientific officers, experimental officers and assistants, respectively. More inform-tion is needed; but the indications are that ab a 5 ft. length of draining board is sufficient fo scientist, and up to 8 ft. is required for an assista These figures would remain about the same for sm working-groups, since sinks for washing up are rar used simultaneously by several people.

Table 1. Bench-Length required for Various Groups o Scientists and Assistants

| Number of scientists | Number of assistants | Proportion of time that the bench-length will satisfy the group's requirements 95% | 96% | 97% | 98% | 99% |
|---|---|---|---|---|---|---|
| | | ft. | ft. | ft. | ft. | ft. |
| 1 | 0 | 10·4 | 11·0 | 11·6 | 12·4 | 13·7 |
| | 1 | 18·0 | 18·6 | 19·5 | 20·6 | 22·3 |
| | 2 | 25·1 | 25·9 | 26·9 | 28·2 | 30·3 |
| | 3 | 31·7 | 32·8 | 33·9 | 35·4 | 37·8 |
| 2 | 0 | 15·9 | 16·6 | 17·5 | 18·8 | 20·6 |
| | 1 | 22·9 | 23·8 | 25·8 | 26·2 | 28·4 |
| | 2 | 29·7 | 30·7 | 31·8 | 33·4 | 35·8 |
| 3 | 0 | 20·8 | 21·7 | 22·8 | 24·2 | 26·4 |
| | 1 | 27·5 | 28·5 | 29·7 | 31·3 | 33·8 |
| 4 | 0 | 25·4 | 26·4 | 27·6 | 29·3 | 31·8 |

## Provision of Services

Another aspect of laboratory design on which t survey material has some bearing is the provision various services to the bench. For example, da taken from the pilot survey show the average made of cold-water taps. From this the probabil distribution of the number of taps in use at a moment can be found. If a man were provid with four taps, then on certain reasonable assum tions it can be shown that he would use no water 92·2 per cent of the time, one tap being in use 7·5 per cent, two taps for 0·2 per cent and three four taps for a negligible proportion of the tim Service pipes and drains adequate to deal with t taps full on at any moment would in general entirely satisfactory. The main point to be ma here is that this is the kind of information requi on which to base standard methods of calculati leading to an efficiently designed service installati Similar data were obtained for hot water and d tilled water. Drainage calculations should take i account all forms of waste water. Data were a obtained for coal gas supplies, and similar calcu tions show the provision necessary to meet a required proportion of total requirements.

Another service of great importance is elect supply. One way of studying the material is to c sider the number of electric points in use at a instant, as with taps for gas or water. It is like on general grounds, that such an approach wo be very inexact for electricity supplies, as the curr used is often very much less than the maxim rating of the socket or fuse. An alternative appro is to consider the variation in the actual amount current used by an individual. Thus it was fou that although scientists used on average 0·60 am a.c. at the usual 230-volt level, 4 amp. would needed to cover the requirements for 98 per cent the time. The needs of a group of workers could a be calculated as was done for bench-length.

## Requirements for Illumination

Information was also collected, using the Illumi ating Engineering Society's code values[4], on size detail and contrast occurring in the work done the scientists. The results are given in Table 2.

ble 2. PERCENTAGE OF TIME THAT VARIOUS COMBINATIONS OF TAIL AND CONTRAST OCCURRED IN THE WORK OF SCIENTISTS IN LABORATORIES (EXCLUDING READING AND WRITING)

| Size of detail | Contrast | Scientific officers | Experimental officers | Assistants | Scientific officers and experimental officers together |
|---|---|---|---|---|---|
| licroscopy | — | 5·0 | 7·3 | 2·5 | 5·6 |
| linute | Good | 3·0 | 0·0 | 0·3 | 2·3 |
| linute | Average | 2·4 | 0·0 | 0·2 | 1·8 |
| linute | Poor | 2·9 | 4·2 | 1·1 | 3·3 |
| mall | Good | 3·4 | 3·4 | 1·7 | 3·4 |
| mall | Average | 21·8 | 23·7 | 22·5 | 22·3 |
| mall | Poor | 11·2 | 12·1 | 21·2 | 11·4 |
| rdinary | Good | 2·2 | 0·0 | 0·0 | 1·6 |
| rdinary | Average | 0·1 | 1·9 | 0·2 | 0·6 |
| rdinary | Poor | 1·2 | 1·1 | 2·9 | 1·2 |
| ark room | | 0·1 | 0·0 | 0·3 | 0·1 |
| eneral activities | | 46·6 | 46·3 | 47·2 | 46·5 |
| | | 99·9 | 100·0 | 100·1 | 100·1 |

Such data will help in specifying the artificial umination needed, and can also be used to assist design for natural daylight. The daylight anticipated at any point in a proposed laboratory can be calculated from drawings by techniques already established, and compared with the requirements for scientific work. (To assist such comparisons, a study of reflexion factors in typical laboratories is needed, and this is at present in progress at the Building Research Station.)

## Time Spent Reading and Writing

Time spent in reading and writing has an influence on laboratory design: it affects decisions as to whether separate office space is necessary for some scientists, and whether laboratories should be designed with space for desks as well as benching. The percentages of the time spent reading and writing while in the laboratory were found in the pilot survey to be 33·8, 30·2 and 7·6 per cent respectively for scientific officers, experimental officers and assistants.

# THE CHEMISTRY OF INSULIN

N the *Biochemical Journal* of August 1955 (Volume 60, No. 4) is a communication (pp. 541–556) titled "The Disulphide Bonds of Insulin", by P. Ryle, F. Sanger, L. F. Smith and Ruth Kitai, wards the end of which appears the statement: he results are summarized in Table 10, which gives e complete structure of insulin". The insulin ferred to is from ox pancreas, and in the following per ("The Structure of Pig and Sheep Insulins", H. Brown, F. Sanger and Ruth Kitai, pp. 556–5) the small differences in structure between pig, eep and ox insulins are elucidated.

Dr. Sanger has thus brought to completion the searches which he initiated in 1945 with a paper "The Free Amino Groups of Insulin"[1]. In this st communication he described the use of dinitro-iorobenzene for the identification and estimation of e free amino-groups of proteins and peptides, a ethod which depended upon the fact that dinitro-iorobenzene reacts rapidly with the free amino-oups of proteins under very mild conditions. ydrolysis of the dinitrophenyl derivative of the otein thus formed yielded coloured derivatives, adily separable by chromatography, of those nino-acids which had reacted with the dinitro-iorobenzene. With this new and powerful tool, nger was able to show that if the molecular weight the sub-unit of insulin was assumed to be 12,000, ere were six free amino-groups present, two of ese on glycine residues, two on phenylalanine sidues and two on the epsilon amino-groups of sine.

At the time that Sanger began this work, the nino-acid composition of insulin was known with a asonable degree of certainty, largely as the result the careful analyses of Chibnall and his colleagues; d, on the basis of crystallographic measurements d of findings with the ultracentrifuge, the molecular eight of insulin was believed to be either 36,000 or ,000, with perhaps a sub-unit of 12,000. Later, easurements of osmotic pressure suggested a figure 48,000[2]. The task that faced one who wished to determine the complete structure of a protein of this molecular weight would have caused many a lesser man to quail; but fortunately Sanger was not deterred by the immensity of the task. The next important step was the demonstration that oxidation of insulin with performic acid, to break disulphide bonds, led to two separable fractions, the *A* or glycyl chain, and the *B* or phenylalanyl chain[3]. By partial hydrolysis of the two fractions with acid or enzymes[4], and the application of the dinitrofluorobenzene method to the separated peptides which had thus been formed, Sanger and his colleagues were able to elucidate the sequence of the amino-acids in the *A* and *B* chains. Ultimately they demonstrated that their results were compatible with the view that the insulin molecule is built up of two chains, joined by two disulphide linkages, and that the sequence of amino-acids in these chains was, for ox insulin, unique and completely determined. The position of a third disulphide linkage was, at that stage, still obscure. In the meantime the results of others[5] had shown that the molecular weight of insulin was in fact about 6,000, although aggregates could easily be formed. Thus the structure which Sanger had studied was indeed that of the molecule.

The identification of those dicarboxylic amino-acids which possessed an amide grouping[6] involved hydrolysis under very carefully controlled conditions. Finally, the publication to which we have already referred, in the August issue of the *Biochemical Journal*, described the determination of the position of the disulphide bonds by the subjection of insulin to partial hydrolysis, by chymotrypsin and under other conditions in which the disulphide bonds were stable. The cystine-containing peptides in the hydrolysate were separated and their structures determined by the methods previously developed. The structures of the cystine peptides which thus emerged permitted only one solution to the problem of the distribution of the disulphide bonds in insulin, and the conclusion was drawn that in one chain a disulphide linkage spanned six amino-acid residues in a manner similar to that deduced by du Vigneaud and his colleagues for oxytocin and vasopressin[7].

As *The Times* said on September 5 of Dr. Sanger's work, "It has not only involved an immense amount of painstaking manipulative operations at the laboratory bench, but, what tends to be over-looked, it rests just as essentially on hard logical thinking, in planning the attack and interpreting its results". Nobody who has read Dr. Sanger's papers will dissociate himself from this view. At each step in the development of the work the methods necessary for the solution of the particular problem have been invented, critically surveyed and effectively applied to the problem in hand. The elucidation of the manner in which the multitude of the smaller peptides which were obtained as the result of partial hydrolysis could be fitted together to yield unique structures for the *A* and *B* chains was itself a masterly achievement. The fact that at each stage the results could be interpreted in only a unique fashion demonstrated the validity of the methods used in a manner that was completely convincing. No investigator in this field has disagreed with the results of Sanger's investigations, and now that we know the structure of insulin to be what he finds so far as the chemistry of the problem is concerned, it is for the crystallographers to tell us exactly how in space the structure deduced by Dr. Sanger is to be distributed. There is also the question of the forces involved in the aggregation of the unit molecules. These matters a the subjects of active investigation at the present tim

In his now classical elucidation of the structur of the octapeptides, oxytocin and vasopressin, Vigneaud based much of his method upon th evolved by Sanger. In the development of his studi du Vigneaud was able to go further than is n possible with a structure like insulin, and succeed in effecting a complete chemical synthesis of ox tocin and vasopressin, an achievement which h earned him this year's Nobel Prize for Chemist Sanger's work has indeed opened up the possibili that insulin itself may ultimately be complete synthesized in the laboratory, although this cann occur for some time yet.

Sanger's methods and example have set in moti a large force of endeavour in the investigation protein structure, the limits of which have yet to visualized. What is now happening perhaps w illustrates the old saying "imitation is the sincere form of flattery".

# NEWS and VIEWS

## Chemical Microbiology at Oxford:

### Prof. D. D. Woods, F.R.S.

The promotion of Dr. D. D. Woods to the new Iveagh professorship of chemical microbiology in Oxford will be warmly welcomed by those who are aware of his distinction in his field. Prof. Woods received his early training in Cambridge, where he worked under the inspiring guidance of the late Dr. Marjorie Stephenson. In 1939 he joined the Medical Research Council Unit for Bacterial Chemistry under Dr. (now Sir) Paul Fildes; he went to Oxford in 1945 and was appointed reader in microbiology in 1946. Among his many contributions is the discovery in 1940, while collaborating with Sir Paul Fildes, of the mechanism of action of sulphonamide drugs; he established the competition between sulphonamides and *p*-aminobenzoic acid, a normal cell constituent which had not been recognized before as such. From 1940 until the end of the War his academic research was interrupted by service with a Ministry of Supply research team (led by Sir Paul Fildes) to study defence against biological warfare. At Oxford he has built up a flourishing school of chemical microbiology. He is at present interested mainly in the synthesis of vitamins and amino-acids by micro-organisms.

The institution of the new professorship has been made possible by a generous endowment from Arthur Guinness, Son and Co., Ltd. This firm has already provided three Guinness research fellowships at Oxford which enable senior research workers to carry out full-time research on the biochemistry of micro-organisms. The many benefactions to scientific research made by Lord Iveagh (who is head of the house of Guinness) were referred to in *Nature* of June 4, p. 975, on the occasion of his appointment to the Order of the Garter.

## Botany at St. Andrews:

### Dr. J. H. Burne

Dr. J. H. Burnett, lecturer in the University Liverpool, has been appointed to the newly create chair of botany at the University of St. Andrew Dr. Burnett entered the University of Oxford 1940 as a Postmaster scholar of Merton and, aft taking the shortened degree course, was commission in the Navy. During his service, which was main in the Mediterranean, he commanded a landing-cra and was both wounded and mentioned in dispatche On returning to Oxford, he took Schools agai obtaining a first class, and was elected to a Christoph Welch scholarship. He became a University demo strator in botany in 1949 and was for a time actu curator of the Fielding Herbarium. In January 19 he moved to the University of Liverpool as lectur in botany. Dr. Burnett's interests lie mainly in th application of the broader genetical principles biological problems. Since 1953, his work on fung genetics has been supported by a grant from th Nuffield Foundation. His early studies were on th physiology of the mating process in *Mucor*; but mo recently he has been interested in the matin mechanisms of the Basidiomycetes and, in particula the problem of estimating the population size b using mating alleles as markers. In Liverpool h played an active part in the running of a geneti discussion group among the medical staff of th hospitals.

## Nematology at Rothamsted Experimental Statio

### Mr. F. G. W. Jon

Mr. F. G. W. Jones, lecturer in agricultur zoology in the School of Agriculture, Cambridge, ha been appointed head of the Nematology Departme of Rothamsted, and will take up his new duties January. Educated at Queen Mary's Gramm hool, Walsall, and Jesus College, Cambridge, he ad botany, zoology and chemistry for Part I of the tural Sciences Tripos, and zoology (specializing in tomology and experimental zoology) for Part II. e graduated B.A. in 1936 and M.A. in 1941. In 37 he was attached to the old Agricultural Advisory rvice at the School of Agriculture at Cambridge, ad on the discontinuation of the Service he was pointed successively University demonstrator (1946) ad University lecturer (1947). In these roles and as rector of studies in agriculture at Jesus College he as been closely concerned with undergraduate and stgraduate education. His research work has been iefly on plant nematodes. As adviser to the Com- ittee for Sugar Beet Research and Education since 46, he has attracted to his side an active research am for working on sugar beet pests, principally the gar beet eelworm, *Heterodera schachtii*. The use of icroplots', each a few square feet in area, has cilitated adequate mixing and sampling of field ils and has yielded valuable data on changes in e population of beet eelworm under various gronomic conditions. Other lines of work have alt with the host ranges of this and other eelworms, ad the effects of different levels of soil moisture on e hatching and migration through the soil of *eterodera* larvæ.

## ycology and Bacteriology at the Weizmann Institute of Science, Rehovoth :

### Dr. Esther Hellinger

Dr. Esther Hellinger, who is retiring from her st as chief mycologist and bacteriologist at the aniel Sieff Research Institute, now part of the 'eizmann Institute of Science, Rehovoth, is one of e band of enthusiastic scientists who have done so uch for plant pathology and industrial mycology in rael. Her investigations have covered a wide field id have all been concerned with problems of prac- cal importance. Her first task was examining perimental shipments of grapes to Britain, every cility for this work being given in London by the te Sir Edwin Butler at the Imperial Bureau of ycology (now Commonwealth Mycological Institute). 1926 she went to Palestine again and worked under r. I. Reichert at the Agricultural Experiment ation, Tel Aviv, on a number of local plant diseases. uring 1928–31 she undertook the investigation of e wastage of citrus and other fruits then causing much concern to exporters, a project financed intly by the Empire Marketing Board and the lestine Government. Her association with Dr. eichert continued in 1932, and a number of joint pers were published by them chiefly on citrus and nana storage diseases. Late in 1932 Dr. Weizmann vited her to join his staff at the Daniel Sieff Research stitute as chief mycologist and bacteriologist, and e then turned her attention to studies on fermenta- on processes and the retting of flax. Dr. Hellinger's ntribution to science is considerable both in antity and quality, and it is to be hoped she will ng enjoy her well-earned retirement.

## ew Polarographic Laboratory of the Cambridge Instrument Co., Ltd.

The Cambridge Instrument Co., Ltd., has recently ilt a small extension to its research department, ich is to be used exclusively for work in polaro- phic problems and techniques, and on November Prof. J. Heyrovský, of Prague, formally opened e building. The Cambridge Instrument Co., Ltd., is a pioneer among makers of polarographs in Great Britain, the earliest instruments being sent out just before the Second World War, and Dr. G. Jessop, of the Company's research department, has done a large amount of work on the development of polarographic instruments and techniques. During recent years the volume of original and outside consultant work has so increased that the new polarographic research laboratory has become necessary. The laboratory will be in the charge of Mr. W. J. Parker, and its specialized services will be available for advice and help to firms and to research workers interested in this subject.

## Institution of British Agricultural Engineers

The Institution of British Agricultural Engineers has moved into new premises at 6 Buckingham Gate, London, S.W.1, and all future sessions of the London open meetings of the Institution will be held there.

A new local centre of the Institution has been inaugurated, covering the counties of Monmouthshire, Gloucestershire, Herefordshire, Wiltshire, Somersetshire and Dorsetshire (east of Bridgwater to Dorchester). It will be known as the Western Centre, and its meeting places will be in Bristol and Chippenham.

## Unclassified Reports on Atomic Energy

Unclassified reports on atomic energy have hitherto been made available to the public by the United Kingdom Atomic Energy Authority at the Science Museum Library in London and the Sheffield Central Library. To provide for the increasing demand for such documents, particularly from industry, they will now also be sent to the following libraries: Central Library, Birmingham; Mitchell Library, Glasgow; Central Library, Liverpool; Central Library, Manchester; Central Library, Newcastle. Documents deposited in these libraries are freely available to the public, and the libraries have agreed to supply photostat copies at their usual rates on request. The documents are also sent to the copyright libraries and to the Patent Office Library, and some are on sale through H.M. Stationery Office. A monthly list of Authority documents available to the public in depository libraries (including those on sale through H.M.S.O.) is to be issued from the Atomic Energy Research Establishment at Harwell on behalf of all Authority establishments. This list will also include papers published in the scientific and technical press, and an indication of whether reprints of these papers are available. Requests to be put on the mailing list should be sent to the Librarian, Atomic Energy Research Establishment.

## Digital Computers of the United States National Bureau of Standards

Since 1946, the United States National Bureau of Standards has been actively engaged in the general field of electronic digital computers, largely for other agencies of the United States Government. The computer programme has been conducted jointly by the Electronics and the Applied Mathematics Divisions of the Bureau: the Electronics Division in Washington, D.C., has been concerned with the development and construction of the two computers (SEAC and DYSEAC), components research and development, and various technical and advisory services; and the Applied Mathematics Division has conducted research on numerical analysis of importance in the solution of problems by computers and the design and construction of the computer (SWAC) at the Bureau's Institute of Numerical Analysis at Los Angeles. Circular No. 551 of the National Bureau of Standards (pp. 146. Washington, D.C.: Government Printing Office, 1955; 2 dollars) is a bound book in which the more important engineering aspects of the Bureau's electronic computer programme are presented. It is based largely on the experience gained in relation to SEAC (National Bureau of Standards eastern automatic computer) and DYSEAC (second SEAC). The contents of the circular consist of eight articles, in addition to an introduction by S. N. Alexander, who gives a brief résumé of the historical development of the programme. The topics discussed in the articles include dynamic circuitry techniques, design of systems, high-speed memory development, input-output devices, construction and maintenance, in addition to a review of three years of operational experience on SEAC.

Both SEAC and DYSEAC are high-speed, automatically sequenced, electronic digital computers, in which extensive use is made of germanium diodes for switching and gating. They have mercury delay-line internal memories, and SEAC has an additional electrostatic memory. Since September 1950, SEAC has been in almost continuous daily use, but interspersed with its productive computational operation there have been periods during which research and development have been conducted on it. The new constructional techniques that have resulted from the experience with this computer have been incorporated into DYSEAC, and this latter represents a considerable advance in the computer art, though it was designed to serve as an experimental nucleus for more complex data-processing networks.

## The Shape of the Earth

THE different methods for determining the Earth's ellipticity $c$ are discussed by G. Tiercy in No. 50, Series *A*, of "Publications de l'Observatoire de Genève" (Fasc. 1 of Vol. 6). The four main methods are: the geodesic method by measuring the length of 1° of the arc of a meridian; the determination of gravity at various latitudes; the precessional method; and the perturbations observed in the motion of the Moon. While the geodesic value 1/297, adopted in 1911 by the International Conference of Astronomical Ephemerides, is adhered to, nevertheless there exists some uncertainty regarding its accuracy, for the value of 1/294, obtained from the results of the lunar dynamics, still presents a difficulty in accepting a unique and definitive value of $c$. Reference is made to Bulletin No. 78 of the United States National Research Council, published in 1931, which contains a memoir by W. D. Lambert, who expressed the opinion that the dynamic solution could be made to approximate to the geodesic solution if one or the other of three possibilities was accepted: changes in the values of the secular variations deduced from observations; changes in the data for the Earth's figure; and contingent corrections in the very complex mathematical theory of the problem. Tiercy then proceeds to consider another possibility, which may be briefly summarized as follows. In 1932 Wavre dealt with the problem of the oblateness of the Earth, retaining terms of the order of $\omega^4$, $\omega$ being the angular velocity, and obtained for the terrestrial meridian a slightly flattened curve with reference to an ellipse with the same poles and the same equatorial radius. The theoretical value of the flattening obtained by Wavre was $c = (a - b)/a \doteqdot 1/295$, a
the small portion $\Delta$ intercepted by the radius betwe
the two curves is derived from $\Delta = \frac{1}{4} kb\omega^4 \sin^2$
where $k$ is a constant and $\varphi'$ the geocentric latitu
From this it was found that $\Delta = 310$ metres. Wi
the aid of two diagrams, Tiercy shows that Wavr
investigations practically eliminate the discrepan
which was obtained for $c$, by the following co
promise. Taking the surface of the Earth to confor
to the international ellipsoid ($c = 1/297$) but flatten
in accordance with the formula given above, t
flattened globe would behave very closely, from t
point of view of lunar dynamics, as an ellipsoid
which $c = 1/295$. Admitting that it is only a co
promise, it is suggested that it can last until a mo
ingenious interpretation will produce reconciliati
of the different results.

## Year Book for 1955 of the Library Association

A FEATURE of the Year Book, 1955, of the Libra
Association (pp. 193; from the Association, Londo
21s.; 15s. to members) continues to be the us
graded list of text-books and works of referenc
which has a value far from confined to those pr
paring for the examinations of the Association, t
regulations and syllabus for which are also give
The entries under science and technology are w
chosen and balanced, and the scientific worker hi
self might well turn to these lists for references
books on general science, including the history
science, natural history and biological sciences. F
the science teacher they should be particularly usef

## American Association for the Advancement Science: Meeting in Atlanta

THE 122nd meeting of the American Associati
for the Advancement of Science will be held
Atlanta, Georgia, during December 26–31. Sixte
sections of the Association and approximately sixt
five affiliated and associated societies will meet co
currently in Atlanta. The programme includes
joint meeting of the Association with the Oak Rid
Institute of Nuclear Studies, at which twenty-tw
papers on "Atomic Energy and Agriculture" will
given, and three symposia on, respectively, the ne
psychiatric drugs, the treatment of alcoholism, a
recent concepts in clinical chemistry. Dr. James
Killian, jun., president of the Massachusetts Institu
of Technology, will give the Sigma Xi Lecture, a
Mr. Newman Bumsted, assistant chief of cart
graphic staff, the National Geographic Societ
Lecture, his subject being "Atlantic's Farthe
Shores". Further information about the meeting c
be obtained from the Director of Public Informati
of the Association, Dr. Sidney S. Negus, Medic
College of Virginia, Richmond, Virginia.

## Soviet Science To-day: Symposium in London

A SYMPOSIUM on "Soviet Science To-day", arrange
by the Society for Cultural Relations with th
U.S.S.R., will be held on November 29 at 7 p.m.
the Caxton Hall, Victoria Street, London, S.W.
The symposium will take the form of a question-an
answer meeting, and questions should be submitte
in advance. Three aspects of current developmen
in the U.S.S.R. will be considered by the following
Academician N. V. Tsitsin, director of the Permane
Agricultural Exhibition, Moscow (on agriculture)
Prof. C. F. Powell, professor of physics in th
University of Bristol (on atomic energy); and D
S. Lilley, of the Department of Extra-Mural Studi

iversity of Birmingham (on automation). In dition, Mr. J. Allan Cash, a photographic journalist, ll show slides of a number of photographs which he ok last August in the U.S.S.R. Prof. Powell and . Lilley have also visited the U.S.S.R. during gust and September of this year. Admission kets to the symposium (price 2*s*.) and further formation can be obtained from the Society for ltural Relations with the U.S.S.R., 14 Kensington uare, London, W.8.

## ineralogical Society

The following have been elected officers for 1955– of the Mineralogical Society: *President*, Prof. L. awkes; *Vice-Presidents*, Dr. F. A. Bannister and r. F. Dixey; *Treasurer*, Prof. J. H. Taylor; *General cretary*, Dr. G. F. Claringbull; *Foreign Secretary* d also *Editor of the Journal*, Dr. L. J. Spencer.

With the issue of No. 231 (December 1955) of the *ineralogical Magazine*, Dr. L. J. Spencer will retire om the editorship, having completed fifty-five years . this honorary office, to which he has devoted his hole time since he retired in 1935 from his post as eeper of minerals in the British Museum (Natural istory). The work involved is now so onerous that e Council of the Society has decided to appoint two litors, one of the *Magazine* and one of the *Abstracts*; e new editors will be Dr. M. H. Hey and Dr. . F. M. Henry, respectively. The Society has cently moved its offices from Burlington House, nd its new address is now 41 Queen's Gate, South ensington, London, S.W.7.

## he Night Sky in December

New moon occurs on Dec. 14d. 07h. 07m., U.T., nd full moon on Dec. 29d. 03h. 44m. The following njunctions with the Moon take place: Dec. 5d. 5h., Jupiter 6° N.; Dec. 10d. 18h., Mars 4° N.; ec. 12d. 07h., Saturn 4° N.; Dec. 16d. 20h., Venus ° S. Mercury, in superior conjunction on December , is unfavourably placed for observation during the onth. Venus sets at 17h. 10m., 17h. 35m. and 18h. 5m. on December 1, 15 and 31, respectively, and is isible for some time after sunset; but owing to its rge southern declination it does not attain a great ltitude. Its stellar magnitude varies from −3·3 to -3·4, the visible portion of its illuminated disk ecreasing from 0·923 to 0·870; its enhanced rightness is due to its distance from the Earth ecreasing from 142 to 129 million miles. Mars rises bout 4h. 15m. during December; it moves from a osition near κ Virginis early in the month to about idway between α and γ Librae towards the end of e month, its stellar magnitude varying from 1·9 to ·8 and its distance from the Earth between 215 and 95 million miles. Jupiter rises at 22h. 35m., 21h. 0m. and 20h. 40m. on December 1, 15 and 31, spectively, and remains fairly close to α Leonis, its otion being westward until December 18, after hich it is eastward. Its stellar magnitude varies om −1·8 to −1·9 owing to its distance from the arth decreasing from 478 to 437 million miles. aturn rises at 6h. 30m., 5h. 50m. and 4h. 50m. on ecember 1, 15 and 31, respectively. Its eastward otion from near γ Librae towards Scorpius can be bserved, its stellar magnitude varying from 0·7 to ·8; owing to its southern declination, it will not ttain an elevation of 22° during the month in the titude of Greenwich and is not very well placed r observation. Occultations of stars brighter than agnitude 6 are as follows, observations being made at Greenwich: Dec. 3d. 04h. 02·8m., 5 Cnc. (*R*); Dec. 4d. 02h. 48·7m., α Cnc. (*D*); Dec. 4d. 03h. 49·8m., α Cnc. (*R*); Dec. 7d. 02h. 20·2m., ε Leo (*R*); Dec. 26d. 02h. 28·3m., δ Ari. (*D*); Dec. 27d. 03h. 56·3m., 51 Tau. (*D*); Dec. 27d. 04h. 18·4m., 56 Tau. (*D*); Dec. 28d. 01h. 58·0m., η Tau. (*D*); Dec. 30d. 06h. 40·7m., *f* Gem. (*R*). *R* and *D* refer to reappearance and disappearance, respectively. The Geminid meteors attain a maximum during December 11–13, the radiant being close to α Geminorum. An annular eclipse of the Sun, invisible at Greenwich. takes place on December 14, and will be visible in the Sudan, the Indian Ocean, Thailand and part of China, the partial phase being visible generally over Africa and Asia.

## Announcements

Dr. Otto Maass, principal research officer in the Division of Pure Chemistry of the National Research Council of Canada, and formerly Macdonald professor of physical chemistry and head of the Department of Chemistry of McGill University, has been elected an honorary member of the Chemists' Club of New York. Honorary membership is restricted to about a dozen chemists, and Dr. Maass is the only Canadian so honoured. His scientific work has been mainly concerned with the chemistry and technology of paper.

The National Science Foundation, Washington 25, D.C., has appointed Dr. James M. Mitchell as associate director of the Foundation and Dr. John T. Wilson as assistant director for biological and medical sciences. Dr. Mitchell, a past president of the American Society for Public Administration, was formerly assistant to the director of the Foundation, and Dr. Wilson was formerly programme director for psychobiology.

Prof. J. R. Whitehead, associate professor of physics in McGill University, has been appointed head of the new research laboratories in Montreal of the RCA Victor Co., Ltd. Associated with him will be Dr. Sydney Wagner, also formerly of McGill University, and a number of other physicists, and their work will be in the field of pure physics and electronics research, not necessarily connected with the Company's projects or developments. Prof. Whitehead is British by birth, being a graduate of the University of Manchester and Cambridge, and during 1939–51 he was on the staff of the Telecommunications Research Establishment, working on radar.

Mr. W. F. Grimes, director of the London Museum. has been appointed director of the Institute of Archæology and professor of archæology in the University of London. Dr. E. O'F. Walsh, senior lecturer in the Department of Physiology, the Royal Free Hospital School of Medicine, London, has been appointed to the University readership in biochemistry tenable at that School.

A symposium on the various chemical, biochemical, physiological and medical aspects of heparin, organized by the Società Lombarda di Scienze Mediche e Biologiche, will be held on December 19 in Milan at the Museo della Scienza e della Tecnica, 17 Via S. Vittore. For non-members of the Società Lombarda a registration fee of 1,000 lire will be charged, which will entitle them to a copy of the proceedings. Further information can be obtained from Prof. Walter Montorsi, Pad. Monteggia, Via F. Sforza 35, Milan.

# SOUTH-EAST ESSEX TECHNICAL COLLEGE, DAGENHAM

## EXTENSIONS TO THE SCIENCE DEPARTMENTS

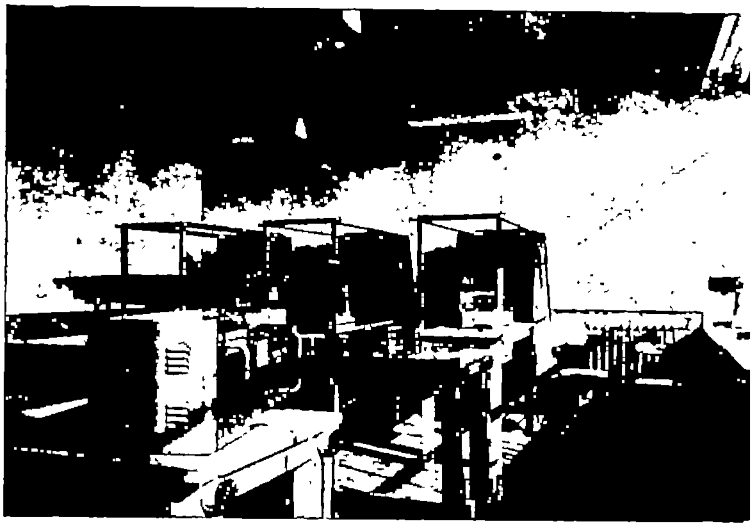

Fig. 2. Advanced Optics Laboratory

It had been apparent for several years that the accommodation for the Science Departments of the South-East Essex Technical College at Dagenham was inadequate. The College was opened in 1936 and at that time there was one Science Department which operated mainly on the ground floor of the now enlarged Science Block. Since that time, the provision of laboratories for the College has remained practically the same, although the demands on this section have developed considerably. One measure of the growth is reflected in the fact that within the past ten years it has been necessary for purposes of organization to split the original Science Department into a Department of Chemistry and Biology and a Department of Physics and Mathematics, and the number of full-time staff has been more than doubled to meet the increased demands. The total number of students attending the College on a full-time or part-time basis is now approximately 8,500, and of these approximately 900 are enrolled in the Science Departments.

The deficiency in accommodation became increasingly noticeable immediately after the Second World War, and early steps were taken to plan extensions to the existing block by which two upper floors would have been added, together with extensions outward to the east and west. This block would have included provision, not only for science and engineering, but also for art, architecture and domestic science. The scheme was approved by the Ministry of Education in 1950, but shortly afterwards, as part of a gener policy of national economy, approval was withdraw however, the Ministry finally gave approval to t present amended scheme. The effect of this has been exclude the extensions outwards to the east and we and to limit the extensions to two new floors abo the original block. In spite of these reductions, t new extensions have resulted in a substantial additio to the accommodation for the two Science Depar ments, with some classroom accommodation for t Engineering Department.

In planning the accommodation and equipmen consideration has been given not only to the nee of existing courses, including degree courses, but al with reference to new types courses in applied science to me the changing needs of industry. T give only one example, a phot graphic section has been include and this will provide courses prin arily to meet the requirements industry, where this technique is increasing importance. It is vital necessary that the departments the College should be abreast modern developments in all the su jects taught and, indeed, in a pos tion to point the way to new a vances in the future. The researc laboratories will enable postgrad ate students to be trained in th methods of research and to wor for higher degrees.

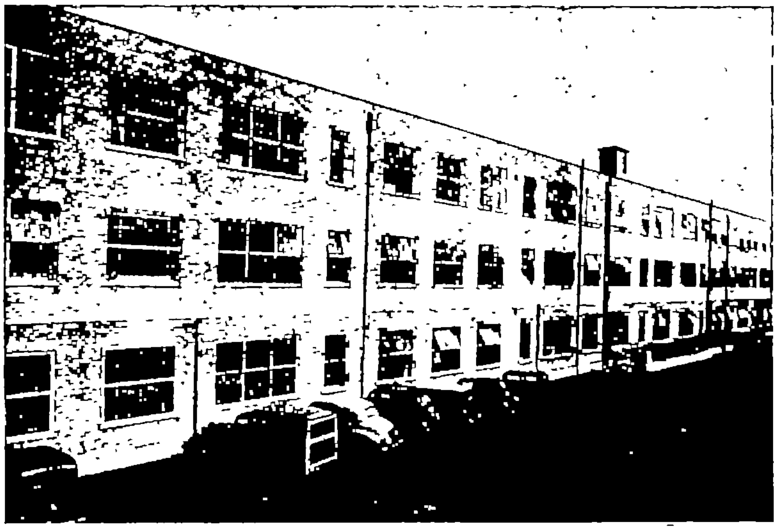

Fig. 1. Science Block extensions ; from the west end

The new accommodation include two chemistry research laboratorie two physics research laboratorie advanced chemistry lecture roo large lecture theatre and labor ies for general chemistry, physical chemistry, radio d television servicing, advanced radio and applied oustics, X-ray and high-vacuum work; general ysics, heat, sound and optics, magnetism and ctricity, advanced optics and photography. Pro- sion has also been made for three engineering awing offices and three engineering classrooms, and physics workshop.

The new laboratories have been well equipped and is only possible to mention a few items; for ample, a high-frequency motor alternator set, ilger standard polarimeter, 'Speedivac' high-vacuum mp, vacuum coating unit, X-ray diffraction equip- ent, measuring microscopes, single-crystal gonio- eter, Brown electronic potentiometer, Brunsviga lculating machines, various special cameras and otographic equipment, equipment for physics rkshop, spectroscopic chemical analysis, radio and levision servicing, audio-radio and high-frequency easurements, electronic measurements, etc.

The Science Departments provide both full-time d part-time courses for B.Sc. special chemistry and ecial physics, and for the general degree of the niversity of London, associateship of the Royal stitute of Chemistry, and graduateship of the stitute of Physics. Part-time day and evening urses are provided for Ordinary and Higher ational Certificates in chemistry, applied physics d engineering, and City and Guilds of London stitute courses in telecommunications, radio engin- ring, radio and television servicing, photography, emical plant operation and metallurgy. Courses ve been offered at various times in nuclear physics, gh-vacuum technique, electronic measurements, lve technology, advanced mathematics for physi- sts, chemists and engineers, statistics, theory and actice of X-ray diffraction, theory and practice spectroscopic analysis, servo-mechanisms, glass- owing and plant technology.

It is proposed to offer a number of 'sandwich' urses suitable to the area served by the College, d these include applied physics, chemistry, radio d electronics, mechanical and production engin- ring, and electrical engineering.

The new extensions were opened on November 19 Mr. Geoffrey Marchand, who was until recently airman of the London Regional Advisory Council r Higher Technological Education, in the presence a representative gathering of the County of Essex d other professional and academic bodies inter- ted in the work of the College.

---

# ASSOCIATION OF SCHOOL NATURAL HISTORY SOCIETIES

## ANNUAL EXHIBITION, 1955

THE seventh annual exhibition of the Association of School Natural History Societies was held the British Museum (Natural History), London, on tober 15. Once more, the main contribution was om member schools, which sent exhibits from widely parated areas. For example, Ackworth School sent a splay illustrating work done in Alderney, Channel lands, and in Ackworth, Yorks. From farther ield came the log-book of the Natural History Society Breeks Memorial School, Ootacamund, India; this cluded some beautifully executed water-colour intings of local avifauna. Living midwife toads and tadpoles (from Provence in France) were exhibited by Glyn Grammar School, Ewell, Surrey.

There were many collections on show, including an extensive comparative display by Bishop's Stortford College of aquatic larvæ from Bishop's Stortford and Flatford Mill, and an equally extensive collection of twenty-seven species of moss from the Lake District shown by University College School, Hampstead. Cranbrook School, the interests of which lay in the lower vascular plants, showed herbarium sheets of local ferns. A collection of dragonflies preserved by vacuum-desiccation to retain the natural colours was exhibited by Lord Wandsworth College, Long Sutton. This and several other entomological exhibits, such as those of Felsted School, Herts and Essex High School for Girls, Bishop's Stortford College and King's School, Canterbury, showed the painstaking care that is taken by these young naturalists to ensure that their specimens are preserved in optimum condition. The wild tropical silk moths exhibited by Tonbridge School were some of the most beautiful creatures on display that day. On the whole, there were more entomological exhibits this year—a fact noted with approval by several visitors.

It is a frequent criticism of the exhibitions that there are "too many graphs"; but nevertheless the compiling of detailed observations and the plotting of transects and quadrats are essential to serious ecological studies. Detailed charts showing the vegetation of East Coast localities were shown by Felsted School. In connexion with local angling interests, Oundle School had made a complete ecological survey of the Willow Brook, a tributary of the River Nene, which is to be stocked with trout. In another exhibit they traced the colonization of spoil heaps, from opencast mining, from bare earth to complete cover, over a period of thirty years. Dauntsey's School showed results obtained in studying the relative frequency of orchids on a Downland site, together with preliminary investigations to account for the observed frequencies. Less detailed, yet also worth while, were the line transects made by Brighton and Hove High School for Girls, which also exhibited a fine collection of local Basidiomycetes. Kimbolton School showed the results of botanical surveys made in the grounds of Kimbolton Castle and at a site on the River Kym. A hundred-yard transect clearly demonstrated the effect of shade upon the composition of the field layer-vegetation.

To many people, graphs and charts are dull, but in fairness it must be said that this year there was a noticeable improvement in the presentation of results: charts were clearly drawn and labelled; captions were short and to the point; and neatness abounded. Those who, in previous years, had produced results which were undoubtedly valuable but were tediously presented now attempted to enliven their charts with colour, bold lettering and other devices. Thus it has been demonstrated this year that members can not merely produce results and specimens, but they can also produce an exhibition. This point is well illustrated by the display put on by the William Grimshaw School, London. "Discovering Coldfall Wood" was a record of what had been found by pupils in an area of woodland. Where actual specimens could not be brought, their place was taken by photographs, models or paintings, so that a visual account of the wild-life of the wood was presented. Another project directed towards visual education was the film strip being produced by Orange Hill Girls' Grammar School, Edgware. This showed stages in the preparation of diagrams for a film strip illustrating the life-history of the honey bee.

The exhibition was supported by three guest exhibitors: the Amateur Entomological Society, the School Nature Study Union and the Universities Federation for Animal Welfare. During the afternoon a colour film, "Coral Wonderland", was shown, describing life in and around the Great Barrier Reef of Australia. A catalogue of exhibits was available, and an enlarged edition of this catalogue, giving an account of the exhibition and a complete list of members, can be obtained from the honorary general secretary of the Association, O. N. Bishop, Kimbolton House, Kimbolton, Huntingdonshire, price 10*d*. post paid.

The general improvement in quality of presentation, together with the maintenance of good scientific standards, are pleasing to note. Many of the exhibits were again on view in the Department of Zoology, University College, Leicester, on November 5, when the Association held its first provincial meeting. It is hoped thereby to encourage more Midland schools to take an active part in the work of the Association.

O. N. BISHOP

# DISSEMINATION OF SCIENTIFIC INFORMATION

A CONFERENCE on the Dissemination of Science, organized by Unesco, was held in Madrid during October 19–22. Twenty-five delegates, representing national associations for the advancement of science and associations of science writers, took part. The United States and most European countries were represented, including Belgium, France, Denmark, Spain, Italy, Western Germany, Switzerland, Greece, Netherlands, Poland, Sweden, Turkey and Great Britain.

A wide range of problems was discussed on an agenda drawn up by the Unesco Secretariat, which agenda was severely criticized by many of the delegates because it failed to embrace the fundamental difficulties of scientific popularization. Nevertheless, many interesting issues were covered, and the widely different practices of the various countries soon became obvious.

Many of the delegates commented on the inaccuracy of scientific contributions appearing in the lay press and on the prevalent tendency of editorial staffs to make unauthorized changes in scientific articles. This particular problem does not exist to any great extent in Great Britain, where almost all papers of repute have a professional scientific correspondent. The position in France, however, appears to be so unsatisfactory that the French Association of Science Writers has devised a scheme which enables newspaper editors to check information rapidly on the telephone. The Association has prepared a chart giving the name and telephone number of scientists prepared to answer questions on given subjects at short notice. The usefulness of such a service is great; but the Conference was at pains to point out that it should be regarded only as a temporary measure, and that the true solution lies in the recruitment by newspapers of adequately qualified scientific writers.

One of the documents prepared by the Drafti Committee under the chairmanship of Sir Ben Loc speiser, a British delegate, stressed the importance popularizing science and improving general scienti knowledge among certain special sections of t community, embracing on one hand children a their parents, and legislators and business men the other.

The future supply of scientists can undoubted be improved by awaking the children's interest science at an early age. Even those who do not ta up science will benefit from wider scientific kno ledge than the present generation. It is importa to interest parents also, for in many cases they w determine the career on which their children w embark. There was considerable discussion on t ways in which this group could be reached.

Mr. C. A. Reichen, of Lausanne, produced a numb of copies of an excellent illustrated children's mag zine, in which scientific matters were given conside able prominence. This magazine has the support a number of industrial firms. It was consider desirable that similar publications should be start elsewhere. The need for more scientific programm on radio and television for children was also discusse

Prof. E. B. Schieldrop, of Norway, spoke on t value of laboratory visits, which had proved pa ticularly successful in the University of Oslo. Sir B Lockspeiser strongly supported this point of vie and said that the most valuable feature of su visits was that children and parents were able to s how scientists worked.

Mr. Watson Davis, director of 'Science Servic an American non-profit-making organization devot to the popularization of science, told the Conferen about the scientific clubs which have become popul among young people in the United States. Fro time to time these clubs organize science fairs— effect conversaziones—in which all the exhibits a made and demonstrated by the members. The science fairs are well supported by local people.

It was considered that the best approach to t second group—those who control government industrial policy—can be made through scientif articles written by scientists and science writers an published in the special journals read by the membe of the group. A notable example of this techniq is the regular publication of articles, on science an its application in industry, in the *Financial Time* Such articles could help greatly in educating busine executives in the possibilities presented by t application of science.

Considerable interest was also shown in the pap prepared by Mr. M. Philips Price, M.P., on th Parliamentary and Scientific Committee. Th informal group, which was started in the 1930's, no has considerable influence both in the House Commons and House of Lords. It acts as a foc point where legislators may meet and discuss scientifi technical and related economic problems with me interested in research. In this way the influenti layman may be kept informed of the part whic science can play in public affairs.

The Conference agreed that such bodies play most important part in furthering knowledge o science and that they should be established in othe countries for legislators and possibly busines executives also.

A considerable amount of time was spent in some what futile discussion of science fiction and "th fight against false sciences". There was also muc rgument as to whether some form of international rganization for co-ordinating the work of national associations for the advancement of science and the ational associations of science writers should be set up. Finally, however, a recommendation was adopted to the effect that it was undesirable at the present moment to establish an international organization for these purposes, but that Unesco should consider the possibility of forming a consultative committee to further co-operation between the various national ssociations if this should prove necessary.

Although the Conference produced no definite or positive conclusions, it was nevertheless valuable in showing that the problems of popularizing science vary greatly from country to country, and in bringing people together with similar interests from many ountries.

T. A. MARGERISON

## ROYAL BOTANIC GARDENS, KEW

A REVIEW of all aspects of the work of the Royal Botanic Gardens, Kew, during 1954, is presented in the *Kew Bulletin*, No. 1, 1955. The past year has been one of sustained progress, but various problems of accommodation remain acute—for example, the Palm House, the Herbarium and library—and are receiving close attention. The main activities of the Gardens, however, are being maintained with unimpaired vigour. It is impossible o touch on more than a few of these in this short article, but some idea of the nature and volume of he problems handled may be indicated by some selected references. Thus, the specimens received for he Herbarium, excluding those prepared at Kew from living material, amounted to 55,994; some ,166 sheets were received on loan; 5,652 were sent on loan; 16,424 sheets were distributed as duplicates; and, in all, some 47,780 sheets were mounted excluding algae, lichens, fungi and bryophyta, and specimens received already mounted). No fewer than 4,077 botanists paid visits during 1954, many of these being from overseas, attending the Eighth International Botanical Congress at Paris. Here, too, reference may be made to the fact that 2,635 nquiries and plant consignments were dealt with during the year.

As in previous years, important activities were the dentification of economic plant products and the supplying of information on economic plants: for example, cinnamon, groundnuts, sesamum, raffia, balsa, senna, sansevieria, capers, opium poppy, aloes, patchouli, pepper, ginger, vanilla and cardamoms. In relation to the present high prices of tea and coffee, various inquiries as to the possibility of growing these crops in new areas received consideration.

For many years the Gardens have rendered an important service to scientific agriculture by maintaining the Quarantine House, the function of which is to prevent the spread of diseases and pests during the transference of economic plants from one part of the world to another. Thus, at the present time, varieties of cacao from the Imperial College of Tropical Agriculture, Trinidad, have occupied most of the available space during the year, these being the most promising of the Imperial College selections of Trinidad trees and some Amazonian forasteros originally collected on the Upper Amazon. Rooted cuttings from these plants have been suitably packed and sent by air to the West African Cacao Research Institute, Gold Coast, and to the Departments of Agriculture in Malaya, Ceylon and Fiji, and, with the exception of a consignment sent to Malaya, are reported to be growing successfully in their new environments. Material of *Theobroma* and the related genus *Herrania*, collected in Colombia in 1952 and sent to Kew via Trinidad, is now on its way to West Africa for the use of plant-breeders there. Various banana and cotton collections are also under surveillance in the Quarantine House.

A further service to countries of the British Commonwealth consists in obtaining plants of potential value. For example, young plants of ipecacuanha (*Cephaelis ipecacuanha* Rich.) have been sent to the Departments of Agriculture in Nigeria, British Honduras and Malaya for local trials.

Work of a rather different kind consists of research on the systematic anatomy of the Monocotyledons; notes on this important and extensive undertaking have appeared from time to time in these columns. Arrangements for the publication of this work in three volumes, of which the first will deal with the Gramineae, have now been made with the Clarendon Press, Oxford. A large number of routine inquiries, relating to miscellaneous botanical materials, including timbers, archæological specimens, and rubbed and powdered herbs, have been dealt with in the Jodrell Laboratory during the year. Among the more unusual samples were nylon bobbins examined on behalf of the Board of Customs and Excise, twigs of alleged apple trees, most of which proved to be plum suckers, submitted by the laboratory at New Scotland Yard, and unsatisfactory pick handles which were found not to have been made of the timber that had been specified.

The report also deals in some detail with the progress that has been made in the preparation of the several regional floras, and with other taxonomic studies, and the cultural work in the different sections of the Gardens is appropriately reviewed. A comprehensive list of publications and a staff list conclude this interesting and important publication.

## OPINIONS AND SOCIAL PRESSURE

WHAT is the effect of the opinions of others on our own? How strong is the urge towards social conformity? An American psychologist, Solomon E. Asch, has approached these questions by means of unusual experiments. These, and his findings, have been described in the November issue of *Scientific American*, which contains a number of other articles of outstanding interest as follows: "Trenches of the Pacific", by R. L. Fisher and R. Revelle; "Synthetic Diamonds", by P. W. Bridgman; "Radiation and Human Mutation", by H. J. Muller; " 'Empty' Space", by H. C. van de Hulst; "What makes Leaves Fall?", by W. P. Jacobs; "Etruscan Metallurgy", by A. N. Modora; "Too Many Deer", by A. S. Leopold[*].

Dr. Asch's investigations were guided by certain underlying assumptions, which to-day are common currency and account for much that is thought and said about the operations of propaganda and public opinion. The assumptions are that people submit uncritically and painlessly to external manipulations by suggestion or prestige, and that any given idea or value can be 'sold' or 'unsold' without reference to its merits. Asch has described his experiments as follows.

---

[*] *Scientific American*, 193 (November 1955), 2 West 45th Street, New York. 50 cents.

A group of seven to nine young men, all college students, are assembled in a classroom for a "psychological experiment" in visual judgment. The experimenter informs them that they will be comparing the lengths of lines. He shows two large white cards. On one is a single vertical black line—the standard length of which is to be matched. On the other card are three vertical lines of various lengths. The subjects are to choose the one that is of the same length as the line on the other card. One of the three actually is of the same length; the other two are substantially different, the difference ranging from three-quarters of an inch to an inch and three-quarters.

The subjects announce their answers in the order in which they have been seated in the room, and on the first round every person chooses the same matching line. Then a second set of cards is exposed; again the group is unanimous. The members appear ready to endure politely another boring experiment. On the third trial there is an unexpected disturbance. One person near the end of the group disagrees with all the others in his selection of the matching line. He looks surprised, indeed incredulous, about the disagreement. On the following trial he disagrees again, while the others remain unanimous in their choice. The dissenter becomes more and more worried and hesitant as the disagreement continues in succeeding trials; he may pause before announcing his answer and speak in a low voice, or he may smile in an embarrassed way.

What the dissenter does not know is that all the other members of the group were instructed by the experimenter beforehand to give incorrect answers in unanimity at certain points. The single individual who is not a party to this pre-arrangement is the focal subject of the experiment. He is placed in a position in which, while he is actually giving the correct answers, he finds himself unexpectedly in a minority of one, opposed by a unanimous and arbitrary majority with respect to a clear and simple fact. Upon him are brought to bear two opposed forces: the evidence of his senses and the unanimous opinion of a group of his peers. Also, he must declare his judgments in public, before a majority which has also stated its position publicly.

The instructed majority occasionally reports correctly in order to reduce the possibility that the naïve subject will suspect collusion against him. There are eighteen trials in each series, and on twelve of these the majority responds erroneously.

How do people respond to group pressure in this situation? First, there are the statistical results of a series in which a total of 123 subjects from three institutions of higher learning were placed in the minority situation described above.

Of the 123 put to the test, a considerable percentage yielded to the majority. Whereas in ordinary circumstances individuals matching the lines will make mistakes less than 1 per cent of the time, under group pressure the minority subjects swung to acceptance of the misleading majority's wrong judgments in 36·8 per cent of the selections.

Individuals differed in response. At one extreme about one-quarter of the subjects were completely independent and never agreed with the erroneous judgments of the majority. At the other extreme, some individuals went with the majority nearly all the time. The performances of individuals in the experiment tend to be highly consistent. Those wh strike out on the path of independence do not, as a rule, succumb to the majority even over an extended series of trials, while those who choose the path of compliance are unable to free themselves as the ordeal is prolonged.

The reasons for the startling individual difference have not yet been investigated in detail. At this point only some tentative generalizations from talk with the subjects, each of whom was interviewed at the end of the experiment, can be reported. Among the independent individuals were many who held fast because of staunch confidence in their own judgment. The most significant fact about them was not absence of responsiveness to the majority but a capacity to recover from doubt and to re-establish their equilibrium.

Many of the individuals suspected that the majority were 'sheep' following the first responder, or that the majority were victims of an optical illusion; nevertheless, these suspicions failed to free them at the moment of decision. More disquieting were the reactions of subjects who construed their difference from the majority as a sign of some general deficiency in themselves, which at all costs they must hide.

Which aspect of the influence of a majority is more important—the size of the majority or its unanimity? The experiment was modified to examine this question. In one series the size of the opposition was varied from one to fifteen persons. The results showed a clear trend. When a subject was confronted with only a single individual who contradicted his answers, he was swayed little: he continued to answer independently and correctly in nearly all trials. When the opposition was increased to two, the pressure became substantial: minority subjects now accepted the wrong answer 13·6 per cent of the time. Under the pressure of a majority of three, the subjects' errors jumped to 31·8 per cent. But further increases in the size of the majority apparently did not increase the weight of the pressure substantially. Clearly the size of the opposition is important only up to a point.

Disturbance of the majority's unanimity had a striking effect. In this experiment the subject was given the support of a truthful partner—either another individual who did not know of the pre-arranged agreement among the rest of the group, or a person who was instructed to give correct answers throughout.

The presence of a supporting partner depleted the majority of much of its power. Its pressure on the dissenting individual was reduced to one-fourth. Most interesting were the reactions to the partner. Generally the feeling toward him was one of warmth and closeness; he was credited with inspiring confidence.

Was the partner's effect a consequence of his dissent, or was it related to his accuracy? There was now introduced into the experimental group a person who was instructed to dissent from the majority but also to disagree with the subject.

Again the results are clear. When a moderate dissenter is present, the effect of the majority on the subject decreases by approximately one-third, and extremes of yielding disappear. Moreover, most of the errors the subjects make are moderate. To this extent the subjects broke away from the majority even while bending to it.

On the other hand, when the dissenter always chose line that was more flagrantly different from the ndard, the results were of quite a different kind. e extremist dissenter produced a remarkable freeing the subjects; their errors dropped to only 9 per t. Furthermore, all the errors were of the moderate riety. It was concluded that dissent *per se* increased lependence and moderated the errors that occurred, d that the direction of dissent exerted consistent ects.

# SCIENTIFIC EXPLORATION OF THE BELGIAN AFRICAN NATIONAL PARK OF THE GARAMBA

By DR. TRACY PHILIPPS

TEN years before the Second World War, King Albert of the Belgians founded the Belgian rican National Parks and the National Parks stitute in Brussels for their scientific study; his ientific adviser was Dr. Victor van Straelen, who s until 1954 director of the Royal Institute of tural Sciences. Dr. van Straelen is president of e National Parks Institute, where he carries out th foresight and energy the founder's purpose, and whom the preliminary report of the Garamba pedition is dedicated by its members. Nominated the King of the Belgians as British member of e Institute, I have for my five-year term taken rt in the scientific administration of the Belgian rican National Parks; the continuing British embers are the Hon. Sir Evelyn Baring, Lord illiam Percy and Lord Willingdon.

The conservation of natural resources, including e recording of their inter-relation, is the more tic of the Institute's two main objectives. In the alm of the natural sciences, the Institute's more namic part is for the improving of natural know-lge of how to reconstitute Nature's ill-used or er-used forces, and how to re-deploy them by w methods towards "delivering mankind from e bondage of ignorance" of himself and his rroundings.

No organization offers better opportunity than the lgian African National Parks for uninhibited servation of natural surroundings, of what grows ere and of what lives there, inter-related and fluenced by the total environment. These reserves re most carefully chosen at the conjunction of eat zoological and botanical zones, and of the eeting places of three main atmospheric currents. tanically, the Garamba Reserve lies within Engler's danic province, which extends roughly from the negal River to the foot of the Ethiopian plateau. he Institute's programme aims at establishing a ientific inventory of the fauna and flora of the serves of which the Government has confided to it e administration. Thanks to the work already done this plan, it can be said that the areas occupied the Institute's four national parks between the dan and Rhodesia have become scientifically the st-known part of the African tropics. Only the ost careful and systematic exploration enabled these sults to be reached, and elements of remarkable terest to be placed at the disposal of organized science. Among the publications issued by the Brussels Institute during the past eight years there can be counted 1,334 new zoological species. These are headed by 561 Coleoptera. From the material collected by the Institute's scientific missions, sixty new botanical species have also been described.

Recently, an important exploration and inventory have been made in the National Park of the Garamba, which lies along the north-western section of the Congo–Nile Divide bordering the Nilotic Sudan. The Garamba is situated on the confines of two great bio-geographic areas, the Guinean and the Sudanic. This recent exploration has been working on a plan differing from its predecessors in the other park reserves. The latter were virtually confined to the collection of zoological and botanical specimens. The Garamba expedition's programme set out to determine all the characteristics of the biological environment, including climate and soil, and then to study the distribution of animals and plants in relation to these conditions. The insect collection alone of the expedition amounts to some 1,500,000 specimens. The number is considerable in view of the sum of the work entailed in the preparation of this fragile and perishable material, which cannot be ready for study before 1956. It will have cost five years in mounting, in the ecological recording of all the conditions surrounding each specimen, and in labelling.

Competent study of collections of this magnitude, essential for serious knowledge of flora and of fauna, present great difficulties due to lack of specialists in various branches of zoology. Thus, several families of insects collected in the Albert National Park (between the Lakes Kivu and Albert, and including Mount Ruwenzori) during the exploration of 1933–35 have not yet been examined for lack of available specialists. The size of the collections from the Belgian African National Parks often constitutes a big problem for the scientist who has to examine them. Thus, an American specialist has found himself charged with the examination of 170,000 specimens of *Chloropidae*, a little fly of which the larvæ of some species live in grass thatch or as parasites on non-vertebrate animals.

It is difficult as yet to appreciate the full value of the results of the recent exploration of the Garamba Reserve. A complete abstract of the observations and collections will first be essential to allow of any general conclusion. The botanical specimens being studied show very numerous species new to the Congo, and one family new to science. The zoological collections from the Garamba include 46,776 vertebrates, of which 2,914 are mammals, 3,122 birds, 4,641 fish, 34,511 frogs, 1,588 reptiles, and a number of albino bats. One bio-geographical discovery has, however, been made. It has long been observed that there is considerable similarity between the fish in the basins of the Nile and of the Congo, without there being any obvious present physical connexion. The Garamba expedition has now found, on the northern border of the Reserve, a marsh situated in a gap in the north-western section of the Congo–Nile divide; this marsh overflows in the rainy season both southward to the Congo towards the Atlantic and simultaneously northward into the Mediterranean basin through the Nile.

Henri de Saeger, who organized and led the Garamba exploration, feels that there is good reason for believing that the results will be found to have brought to science an exceptionally rich contribution.

# ORGANIZATION OF DEFENCE RESEARCH IN THE UNITED STATES

DURING the past three years the expenditure of the United States Department of Defense, the Atomic Energy Commission and the National Advisory Committee for Aeronautics on research and development has been at an annual level of 2,000 million dollars. These activities have recently been reviewed by a Sub-Committee of the Committee on Business Organization of the Department of Defense, and this sub-committee has communicated its findings to the Commission on Organization of the Executive Branch of the Government, by which the report has been approved for publication*. The Sub-Committee was charged with appraising and evaluating such research and development activities and determining the degree of overlapping and the cost of such activities in the Department of Defense and other agencies conducting research related to defence. So far as the Atomic Energy Commission is concerned, the Sub-Committee limited its survey to research and development activities relating to atomic weapons and nuclear power production; but it included those activities of the National Science Foundation that relate to, and are co-ordinated with, the military research and development programmes.

The Sub-Committee's report gives a clear picture of the organization of defence research and development activities in the United States and of the problems encountered in relation to overlapping and co-ordination, the evaluation of new weapons and the use of personnel. In spite of the wide difference in structural organization between the United States and Great Britain, the Sub-Committee's comments and recommendations should be of considerable interest in Britain, both to those concerned with defence research itself and to those concerned with the effective use of scientific and technical man-power and the balance of the effort in research and development, including that between fundamental research and applied research whether for defence or for civil purposes.

Prior to 1953, the Research and Development Board was the only organization in the United States Department of Defense directly concerned with the research and development programmes. Operating through a large group of committees, panels and sub-panels staffed by part-time civilians and officers from the three Departments, the Board did little effectively to co-ordinate and eliminate duplication in these programmes, and in 1953 the Board was dissolved and its functions transferred to the Secretary of Defense, who was provided with an Assistant Secretary (Research and Development). In consequence, a real improvement in effectiveness and economy appears to be developing; but the Sub-Committee doubts whether the new pattern of itself will produce the degree of co-ordination and integration that is desirable, although the professional capacity of the personnel concerned has, in general, been increasing and the traditional attitudes of self-sufficiency of each of the three Armed Services is diminishing. The Sub-Committee emphasizes that it is essential that the Assistant Secretary (Research and Development) be trained in science and te nology. Besides possessing experience in resea and development and their administration, he sho be supported by an adequate staff with li experience, and the Sub-Committee also recommen the full development of the Research and Develo ment Policy Council, of which the Assistant Secreta is chairman. It did not consider, however, that t creation of a further Assistant Secretaryship (Appli tions Engineering) was sound and recommended th if combined operation of the two posts proved unsat factory, as it anticipates, the functions of the t should be integrated into the office of one Assista Secretary. It also recommended that the Secreta of Defense should wisely and fearlessly use h authority to withhold appropriated funds from a research and development project to promote integ tion of the programmes of the three Department prevent duplication and encourage effectiveness a efficiency in the use of research and developme funds.

Substantially all the basic research of the Depa ment of Defense is carried out under contracts plac in the civil economy. This policy is approved b the Sub-Committee, which nevertheless considers th level of 20 million dollars in 1954 too low and reco mends that it be significantly increased. Expenditu on basic research in the physical sciences by th Atomic Energy Commission is regarded as more near in balance with the scope of its activities and with th size of its development programmes. Arrangemen for co-ordinating these basic research programm with that of the National Science Foundation a regarded as excellent, and the present organizati of the Department of Defense is considered adequate for identifying duplication in research a development of weapons if used with continui alertness and energy. The organization does no however, provide adequately for the initiation radically new approaches to systems of weapons, a the appointment of a standing committee of outstan ing scientists and technologists, reporting directl to the Assistant Secretary of Defense (Research an Development), is recommended. This committ could canvass periodically the needs and oppo tunities for studies leading to radically new system of weapons. While the Weapons Systems Evaluati Group of the Joint Chiefs of Staff is potentially great importance and can make contributions of re value, the Sub-Committee recommends that th Group be shifted to contract work with a universit or non-profit organization, and that it then be e panded to an adequate size. An administrative revie of the operations and contributions of the hundre of committees and consultants used by the Depar ment of Defense and the military departments recommended, and those found to be ineffecti should be discontinued. Maximum use should b made of the National Research Council in establishin such committees.

Criticism of the civilian administration of th research and development operations of the thre military departments is severe, and the Sub-Com mittee recommends the establishment of an office Assistant Secretary for Research and Developmen in each of the three military departments. Th Assistant Secretary should be trained in science an technology and experienced in the conduct an administration of research and development an should be assisted by a small staff with simila qualifications.

---

* Commission on Organization of the Executive Branch of the Government of the United States: Sub-Committee Report on Research Activities in the Department of Defense and Defense Related Agencies. Pp. x+91. (Washington, D.C.: Government Printing Office, 1955.) 30 cents.

Commenting on the research and development operations of the three Armed Services, the Sub-ommittee considers that too large a proportion—ome 50 per cent in 1954—of the Army's appropriated unds for research and development is expended on activities within the Army's own facilities and that larger proportion should be shifted to the civil conomy. It commends the new organization plan created in December 1954, but emphasizes the need or strong staff control and for staffing the organization with officers and civilians of the highest technical competence. Of the Navy, it emphasizes the importnce of strong administrative support for the new unctions of the Office of Naval Research in co-rdinating and integrating the research and development programmes of the Navy, and for providing a staff of adequate size and technical competence, though the Navy has gone far to develop such officers. The military organization of the Air Force for research and development appears to be sound, but the Sub-Committee was concerned at the fragmentation of Army and Navy research and development programmes; whereas the Army pattern is potentially adequate to minimize the consequent deficiencies, hat of the Navy is not.

Some 39,000 military personnel and 63,000 civilians participated in the 1954 research and development effort of the three military departments; and while all three departments are giving much attention to personnel problems and have excellent training problems, in view of the increasing national shortage of scientists and engineers, the Sub-Committee recommends that each department should make a realistic examination of its growing needs for technical officers and, if necessary, expand its programmes to provide for an increased number of officers trained in research and development. Each should also revise its policies for such officers so as to permit adequate specialization: the average period of two to three years for the technical assignments is too short. Pay scales should be more nearly competitive with industry, and the number of the higher-level posts in the Civil Service should be materially increased. Where a choice is possible, however, research and development should be carried out at that place in the United States where the work can be done most efficiently and effectively, and it is suggested that some 125–150 million dollars of the programme for 1954 should have been done in the civil economy.

Generally, the Sub-Committee commends the organization for, and the operations in, the military applications of atomic energy, and particularly the Atomic Energy Commission's policy of staff control and co-ordination with operation by civilian contractors. It is concerned, however, that the Department of Defense's assignment of "cognizance" to a military department for certain specific weapons may endanger integration of the development programme and the relations with the Atomic Energy Commission. Unqualified approval is given to the work of the National Advisory Committee for Aeronautics; but it is emphasized that the quality of the work in its laboratories may suffer if salary-levels for professional positions there are not made more nearly competitive with industry. The Sub-Committee anticipates that adoption of its recommendations could bring in the next five years a 25 per cent increase in the effectiveness and efficiency of the present effort in research and development; but it also suggests that in the present rapidly developing technical situation serious consideration should be given to the adequacy of the present level of expenditure.

# THERMAL REACTION BETWEEN HYDROGEN AND NITROGEN DIOXIDE

By Dr. P. G. ASHMORE and B. P. LEVITT

Department of Physical Chemistry, University of Cambridge

THERE has been little published work on the reaction between hydrogen and nitrogen dioxide, although there have been many studies of the effect of nitrogen dioxide on the reaction between hydrogen and oxygen[1]. Ashmore has reported[2] sensitized gnitions of mixtures of nitrogen dioxide and hydrogen, and Pollard and Holbrook have kindly informed us of work in Bristol which shows that the two gases gnite at temperatures above 500° C., and that the products of ignition and of the slow reaction are nitric oxide and water. The present communication outlines results, to be published fully later, of a photometric study of the reaction at about 400° C.

Parallel light of wave-length 4450–5000 A., which s below the photochemical threshold[3] for nitrogen dioxide, passed through a plane-ended, cylindrical, Pyrex' reaction vessel (20 cm. long, 4 cm. diameter) and fell on a 931-*A* photomultiplier tube; the output, when amplified as suggested by Sweet[4], was proportional to the logarithm of the light absorbed and hence to the molecular concentration of nitrogen dioxide. The photometer was calibrated accurately at 102° C. against nitrogen dioxide in the reaction vessel. The linearity and absolute response at 400° C. were shown to be satisfactory by immediate comparison with admitted quantities and also by comparison of kinetic and equilibrium studies for the reaction $2NO_2 = 2NO + O_2$ with published data[5]. The absence of any photochemical effect on the hydrogen – nitrogen dioxide reaction was confirmed by duplicate runs with a neutral density filter (of ¼ per cent transmission) first between the light source and the reaction vessel, and then between the latter and the photomultiplier.

Fig. 1 shows typical plots of the concentration of nitrogen dioxide against time for a wide range of hydrogen pressures, with 10 mm. of nitrogen dioxide present initially, at 411° C. The rate of disappearance of nitrogen dioxide is more rapid the more hydrogen is present. It is also initially more rapid the more nitrogen dioxide is present.

Nitric oxide has a strong inhibiting effect, as shown in Fig. 2; in these experiments, mixtures of nitrogen dioxide and hydrogen were run into nitric oxide already in the reaction vessel. The effect cannot be

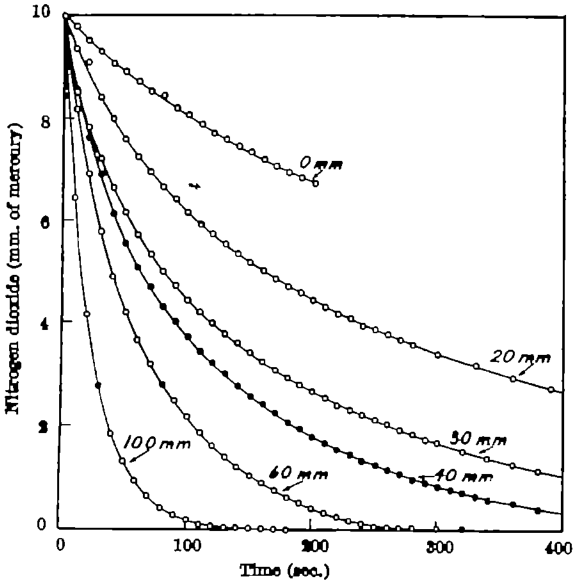

Fig. 1. Decay of concentration of nitrogen dioxide with time. 10 mm. of nitrogen dioxide with indicated pressures of hydrogen, at 411° C.

due to the termolecular reaction between nitric oxide and oxygen, for calculations based on equilibrium data[3] and observed rates for the bimolecular decomposition show that several tens of millimetres of oxygen would have to be present, whereas the amount there is negligible.

The effect of several tens of millimetres of oxygen appears to be negligible initially, but reduces the rate late in the reaction. The effect of water vapour is also slight except near the end of the reaction, when it appears to accelerate the rate of disappearance of the nitrogen dioxide.

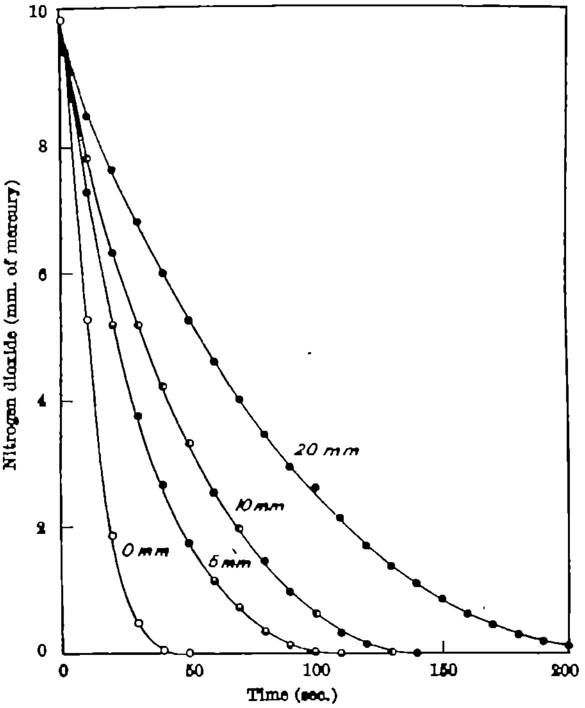

Fig. 2. Inhibiting effect of nitric oxide. 5 mm. of nitrogen dioxide, 100 mm. of hydrogen and the indicated pressure of nitric oxide, at 411° C.

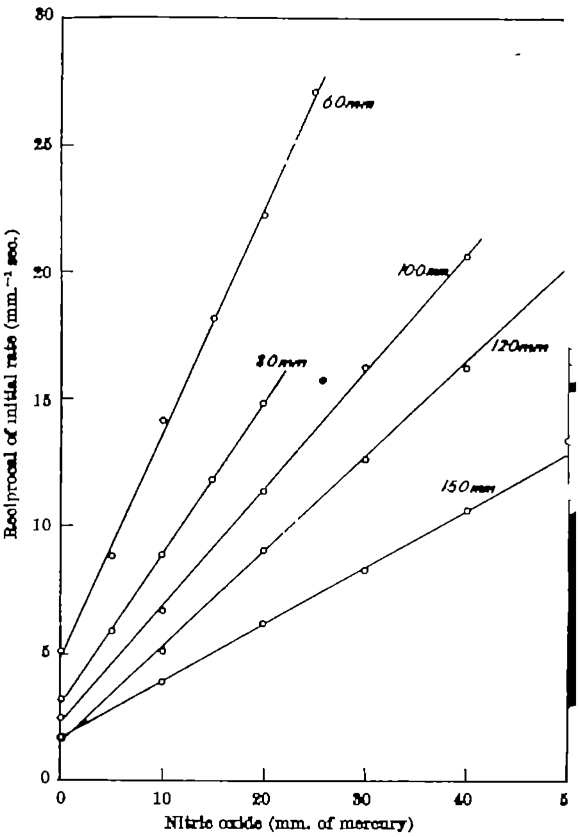

Fig. 3. Plots of the reciprocal initial rate of the inhibited reaction against concentration of nitric oxide added. All runs initially have 10 mm. of nitrogen dioxide and the indicated pressure of hydrogen, at 411° C.

There is no detectable pressure change ($< 0 \cdot 1$ mm.) in the reactions with high ratios of hydrogen to nitrogen dioxide, even when retarded by added nitric oxide. With 10 mm. of nitrogen dioxide and 40 mm. of hydrogen, a pressure increase of 0·2 mm. took place rapidly; this is almost certainly due to the bimolecular decomposition of nitrogen dioxide taking place while its concentration is high. The absence of appreciable pressure change agrees with the stoichiometric equation, $H_2 + NO_2 = H_2O + NO$. An exact analysis of the products has been unsuccessful due to the difficulties of determining accurately small quantities of water vapour; but attempts have shown the bulk, at least, of the products to be nitric oxide and water, as found by Pollard and Holbrook. Calculations for the reaction $3NO_2 + H_2O = 2HNO_3 + NO$ show that the equilibrium concentration of nitric acid is negligible under all reaction conditions[4].

The plots of the logarithm of nitrogen dioxide concentration against time are reasonably linear for the first half-minute with high hydrogen to nitrogen dioxide ratios; the initial rate of disappearance of nitrogen dioxide could thus be determined, and the calculated initial rate of the bimolecular decomposition of nitrogen dioxide subtracted to give the initial rate of the reaction under study.

Fig. 3 shows plots of reciprocal initial rates against nitric oxide added; these are straight lines of reproducible slope, and rather less reproducible intercept, for each ratio of hydrogen to nitrogen dioxide, suggesting the relation:

$$\text{Initial rate} = \frac{A}{[NO] + B}$$

, the reciprocal slope of the lines in Fig. 3, appears be first order with respect to nitrogen dioxide. appears to increase as nitrogen dioxide increases, ut to decrease as hydrogen increases. The values of from the slopes of Fig. 3, and also from plots of itial rates against hydrogen with no nitric oxide lded, suggest an order for the initial rate, with spect to hydrogen, between 1 and 1·5. The order r hydrogen in $A$ is at least unity, but it is hard to ecide how the remainder is apportioned between $A$ nd $B$. This may be cleared up when the photoeter output is amplified and fed to a high-speed corder instead of the present short-period galvanoeter.

Large pressures (about half an atmosphere) of oxygen reduce the initial rate by about 50 per cent, of which calculations show an appreciable part to be due to the reaction $2NO + O_2 = 2NO_2$. However, half an atmosphere of nitrogen also retards the initial rate, although less effectively, so that it is clear that inert gases retard the reaction.

We thank the Royal Society for a grant towards the cost of the photometer, and Dr. B. A. Thrush for his advice on its construction. [July 12

# EFFECTS OF HYPOTHERMIA ON BEHAVIOUR

By R. K. ANDJUS*, F. KNÖPFELMACHER†, PROF. R. W. RUSSELL and AUDREY U. SMITH
National Institute for Medical Research, Mill Hill, London, and Department of Psychology, University College, London

UNTIL recently it was generally believed that +15° C. was the lowest level of deep body emperature compatible with the survival of nonibernating, homoiothermic animals. However, in 951 Andjus[1] reported the reanimation of adult rats fter cooling to much lower body temperatures, uring which prolonged respiratory and cardiac rrest had occurred. Since then, improvements in echniques for reanimating rats subjected to extreme ypothermia have been described, and it is now ossible to maintain body temperature below +15° C. or as long as 70 min. with an expectancy of complete ecovery in a very high per cent of the cases[2-4].

Previous studies have been concerned primarily ith the effects of extreme hypothermia on hysiological processes; during the course of hese studies we became interested in certain eneral observations regarding the behaviour of the nimals. With the exception of a very small number hich showed impaired temperature regulation, nimals appeared to suffer no noticeable after-effects fter successful reanimation from hypothermia t approximately +15° C. or at 0° to +1° C. Animals xposed to the severe treatment recovered reflexes nd posture within two hours of re-warming, and fterwards showed apparently normal activity. lthough there was some reduction in food- and ater-intake during the first 24 hr. after reanimation, here was a return to the normal level or above etween the second and fifth days. Within two or hree days it was difficult, if not impossible, to disinguish between the behaviour of control and xperimental animals living in adjacent cages in the nimal colony. Observations of breeding performnce gave evidence of a temporary impairment of ertility; but the majority of animals had progeny ithin three months of exposure to extreme hypohermia. The offspring were healthy and were reared ormally by their mothers. In general, it seemed hat the very drastic treatment to which the animals ad been subjected was not reflected in any serious, ermanent impairment of their normal behaviour atterns.

This is a preliminary report of research designed to study, by means of certain standardized procedures of comparative psychology, the effects on two aspects of behaviour—learning and memory—of reducing the deep body temperature of non-hibernating, homoiothermic animals. Fifty-six hooded rats from the animal colony at the National Institute for Medical Research were used as subjects in two experiments. In the first, two groups of rats were subjected to identical treatments except that the deep body temperature of one group was lowered to between +1° and 0° C. before both groups began learning a serial problem-solving task. The second experiment was designed to include three groups of animals: a control and two experimental groups, the deep body temperature of animals in one of the latter being reduced to between +13·4° and +13·5° C. and that of the other to between +1° and 0° C. Except for the 'hypothermia' phase of the design, all groups in this second experiment received identical treatments in the following order: training on a maze, hypothermia, tests for retention of the maze habit, and training on a serial problem-solving task.

Deep body cooling was done in two stages. The first involved narcotizing the animals by anoxia and hypercapnia as well as deep hypothermia until they became flaccid and lethargic with colonic temperatures at or below +20° C. Animals cooled to temperatures as low as +13·4° C. re-warmed spontaneously when left at ambient temperatures of +20° C. Other animals were subjected to a second stage in the cooling procedure, during which their body temperatures were lowered to between 0° and +1° C. By use of the technique of Andjus and Lovelock[2], these animals were resuscitated completely even after 60–70 min. at body temperatures below +15° C., and after 40–60 min. without detectable heart-beat, circulation or respiration. The results of research by other investigators[3-5] suggests that cerebral electrical activity may have been arrested for as long as 1½–2 hr. Despite this extreme cooling, there is no evidence[6] of the neurological damage to the brain described by other investigators[7].

The results may be summarized as follows. Animals whose body temperature had been lowered to

---

* Faculty of Science, University of Belgrade.
† Department of Psychology, University of Melbourne.

+ 1°–0° C. showed a significant impairment in problem-solving performance when compared with control animals. On the other hand, no significant differences were found between the performances of control animals and those cooled to +13·4°–+18·5° C. As with such physiological processes as heart-beat and respiration, a body temperature of approximately +15° C. appeared as a 'crucial point' below which performance on later learning tasks was impaired. Our results suggest that this may have been a temporary effect, since the degree of impairment decreased as the interval between body cooling and testing increased.

Although our results show a consistent trend towards poorer retention following hypothermia, the differences among experimental and control groups were very small, and in no instance were they statistically significant. These results support evidence reported by Ransmeier[8] that severe hypothermia, not following immediately after practice of a habit, has little or no effect on measures of memory. This similarity of results is interesting, particularly since Ransmeier's evidence was based upon the behaviour of hibernating mammals following induced hypothermia. Physiological effects of hypothermia at the levels employed are different in such animals from those shown by the rat and other non-hibernating mammals—heart-beat, circulation and respiration being arrested in the latter but not in the former. The fact that suppression of these physiological processes and of electrical signs of brain activity during hypothermia appears to have little or no effect on memory is difficult to explain in terms of a 'dynamic' physiological model[10], in which long-term memory is dependent upon the continuous norm activity of the central nervous system.

Speed of locomotion and amount of food intal were observed in both experiments, and no significa differences were found among the various groups animals during the periods in which the behavio measures were being taken. This suggests that th results reported above cannot be accounted for terms of differences in locomotion or in caloric intal resulting from the different experimental treatmen to which the various groups were subjected.

Within the limits of our experimental procedur we have failed to find evidence that arrest of vit metabolic processes as a result of extreme hyp thermia produces any very serious permanent effec on an animal's behaviour once it has been successfull reanimated. This conclusion is, of course, limite to the types of behaviour we have studied, althoug it conforms with our previous observations ma during the course of research on physiological chang accompanying the lowering of deep body temperatur Before final generalizations are made, it would see desirable to assess the possible effects of hypotherm on other types of behaviour and other species subjects. [July 22

# CHEMISTRY AND INHERITANCE OF FLOWER COLOUR IN THE DAHLIA

By DRS. E. C. BATE-SMITH, T. SWAIN and C. G. NORDSTROM
Low Temperature Station for Research in Biochemistry and Biophysics, University of Cambridge and
Department of Scientific and Industrial Research

AS a result of the work of Lawrence, Scott-Moncrieff, Price and ourselves[1–6], it is known that the following classes of pigments are concerned in the variations of colour in the garden dahlia (*D. variabilis*):

Magenta, purple, crimson and scarlet shades: anthocyanins.

Yellow shades: chalkones, and aurones[6] (benzylidenecoumaranones).

'Ivory' shades (that is, white petals becoming yellow when fumed with ammonia): flavones and flavanones.

Intermediate shades are produced by combinations of these basic pigments.

Lawrence[1] distinguished the following four basic genes as responsible, singly or in combination, for all the colour variations in the species: *A*, light anthocyanin pigmentation; *B*, heavy anthocyanin pigmentation; *Y*, yellow pigmentation; *I*, ivory pigmentation. He interpreted the bottom recessive condition *a b y i* as that present in 'white' flowers, that is, those not becoming yellow when fumed with ammonia. Lawrence and Scott-Moncrieff[4] mention, however, that the petals of some at least of these white genotypes give a pale straw or maize colour when treated, the substance responsible giving a gree reaction with ferric chloride and being "probabl tannin".

It has been of especial interest to us to ascertai the identity of the substances present in the petals o 'white' varieties, since it seemed that this informatio would be essential to the understanding of th mechanism of variation of flower colour in th species.

*D. variabilis* is an allo-octoploid species. Eac of the genes for flower colour may be present in an number from one in the 'simplex' to four in th 'quadriplex'. The genes *A*, *B* and *Y* are expresse in the simplex and higher condition, but the gene must be at least duplex for it to have an effect Without deliberate selection, therefore, recessiv white genotypes appear exceedingly rarely, bu 'whites' can usually be found in a fair-sized plantin of mixed coloured seedlings. A chromatogram fro one such 'white', *DJ*/18, was illustrated in the firs of our publications[5]; but this plant failed to surviv and the present work was carried out with a chanc seedling of the dwarf Coltness strain, here name lare White'. This plant also failed to survive its cond winter, although divided and the portions kept several different storage places. It seems that ese recessive genotypes, as might be expected, are nsiderably lacking in vigour. However, in its cond season, three two-way crosses were made tween 'Clare White' and other single-flowered rieties, and altogether 122 seedlings were raised m the six families. Two of the other parents were bright red and a yellow Coltness variety, and the ird a patterned variety, with a purplish eye, shading rough red-mauve to blue-mauve at the tip. This lend' variety had itself been raised by crossing the mmercial varieties 'Chancellor' (crimson-brown th a deep purple-brown eye pattern) and 'Mrs. 'illiam Clark' (blend, shading from gold at the base rough salmon to red-mauve at the tip). The netic constitution of these parents was not known, d could only be inferred from the distribution of lour forms in the progeny. The numbers of these ere, of course, not sufficient for accurate genetic terpretation of the data.

Of the 122 seedlings, twenty-three were phenopically white. Fourteen gave an overall yellow lour when fumed with ammonia, two a patterned ellow (shaded from base to tip) and seven no yellow ut on longer treatment became maize-coloured and en deep chestnut-brown. Moreover, eight also ut of the first fourteen became a deep chestnut-rown when kept for several minutes in ammonia. was therefore evident that the situation was more mplicated than a simple division into 'white' and vory' genotypes; there appeared to be an interediate group which might be described as 'ivory-hite'. The petal pigments of each of the seedlings ere therefore studied by paper chromatography.

## Identification of the Phenolic Constituents

All the substances with which the present discuson is concerned occur in the tissues of the plant mbined as glycosides or (in the case of caffeic nd other substituted cinnamic acids) as esters. It is ecessary to consider here, however, only the nature f the phenolic residues obtained by hydrolysing e tissue with 2 *N* aqueous hydrochloric acid at 100° nd extracting with a small volume of amyl alcohol f. Bate-Smith[10]). The petal tube and lower part f the petal were not included in the examination, nce in normal flowers these invariably contain ellow pigment. The chromatographic solvent mployed was water/glacial acetic acid/concentrated ydrochloric acid in the proportions (vol.) 10 : 30 : 3 'orestal solvent), in which the anthocyanidins do ot fade and the different constituents are well parated; delphinidin and pelargonidin, for example, ave $R_F$ values 0·30 and 0·68. With a knowledge f the constituents to be expected, chromatograms an be read by inspection in visible and ultra-violet ght, with and without fuming with ammonia. The entity of individual constituents was proved, as ccasion required, by *in situ* ultra-violet spectrohotometry on the paper[11] or by elution of strip hromatograms run on Whatman No. 3 paper[8]. Synhetic specimens of all the substances identified have een available for comparison.

## Phenolic Constituents of 'White' Genotypes

The main constituent, and that responsible in rge degree for the chestnut-brown reaction of the etals when fumed with ammonia, proved to be eriodictyol, in some instances accompanied by naringenin in lesser amounts. The 'ivory-white' genotypes were found to contain, in addition to these flavanones, the flavonols quercetin and (in lesser amount) kaempferol. It is to these constituents and not to luteolin and apigenin that the 'ivory' reaction in these forms is most often due. Luteolin and apigenin were occasionally present as well as flavonols and flavanones. The presence of quercetin and kaempferol was, for reasons discussed later, completely unexpected. Once having been detected in the 'ivory-whites', in which they were present in considerable amounts, smaller amounts could be recognized on the chromatograms of 'white' varieties, and it became clear that the 'white' and 'ivory-white' forms differed only in the relative amounts of flavanone and flavonol that they contained. The flavonols also appeared sporadically among the coloured—especially the paler-coloured and the colour-patterned—progeny of these crosses. They were not, however, present in any of a number of larger-flowered, commercial varieties examined.

## Influence of Parentage on the Occurrence of Flavonols in the Petals

The common parent, 'Clare White', was a true 'white' genotype in Lawrence's sense and contained only a trace of flavonols. The families from the red and yellow parents, respectively, contained the same relative numbers of 'whites' and 'ivory-whites'. The 'blend' crosses produced only one white phenotype, a 'white', containing a moderate amount of flavonol. The genetic equipment permitting the appearance of flavonols in the offspring resulting from crossing with 'Clare White' would seem, therefore, to be shared by all three of the non-white parents. What all four parents had in common, distinguishing them from the commercial varieties examined, was their derivation from the Coltness strain; but it cannot be deduced from this that it was in itself responsible for the presence of flavonols in the petals. Perhaps because of their rarity (and perhaps also their lack of vigour) no 'whites' or 'ivory-whites' other than *DJ*/18 of non-dwarf habit have so far been encountered.

## Significance of the Presence of Flavonols in 'White' Genotypes

There is no reason for disagreeing with Lawrence and Scott-Moncrieff's interpretation of the 'white' condition in flowers of *D. variabilis* as recessive to coloured (including therewith 'ivory'). It is reasonable to suppose (cf. Beale[12]) that, of two allelic genes, that one will be dominant which effects the more elaborate of the two processes expressed, and of all the flavonoid compounds found in *Dahlia*, the flavonols, being the most completely oxidized, should be those requiring the most elaboration in the process of synthesis. Yet it is in a bottom recessive situation that they appear, together with the more expected (because most reduced) flavanones. A certain amount of further information has been obtained by way of a study of the flavonoid compounds in the leaves of a number of genotypes and varieties.

## Phenolic Constituents of the Leaves of Dahlia Varieties

Flavonols, leuco-anthocyanins, and complex substances yielding caffeic, *p*-coumaric, ferulic and sinapic acids[13] are the commonest phenolic constituents of leaves. Of these phenolic constituents, the Compositae do not contain leuco-anthocyanins (*Cosmos bipinnatus* possibly excepted); but the others are commonly present, and *D. variabilis* is not exceptional in this respect. It was found that, irrespective of the colour of the flowers, the leaves of all genotypes contained quercetin, butein, caffeic and ferulic acids, and probably kæmpferol. Of many hundreds of species of plants, including those of a number of closely related Compositae, the leaves of *Dahlia* only have been found to contain butein. Kæmpferol, in Forestal solvent, is overlain by the more highly coloured butein, and when the latter is present cannot be detected by inspection. Its presence in a typical leaf was confirmed, however, as were also the identities of quercetin and butein, by elution from a strip chromatogram as described above.

The situation in the leaf, therefore, as compared with that in the petal, is that the former possesses phenolic constituents—caffeic and ferulic acids—not present (or not conspicuously present) in the latter; it contains quercetin, found in the petals of rare recessive forms only; and it contains a constituent, butein, present in the petal only when a particular gene is present in dominant condition.

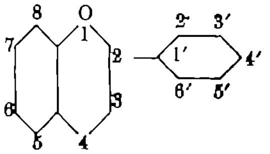
## Theory of Factorial Balance in *Dahlia*

Lawrence and Scott-Moncrieff[4] observed the following gene interactions in *D. variabilis*: in presence of *Y*, the action of *I* is suppressed; in presence of *A* or *B* alone, either cyanin or pelargonin is produced; *Y* in presence of *A* or *B* may suppress the formation of cyanin; *I* in presence of *A* or *B* may suppress the formation of pelargonin; a gene *H* is present the inheritance of which, like that of *A*, *B*, *Y* and *I*, is polysomic; *H* cumulatively inhibits the expression of *Y*. There may also be a gene inhibiting the expression of *I*.

As a working hypothesis, it may be assumed that dominant allelic genes acting in the petals modify a situation present generally throughout the soma. If this is so, the action of *Y* should be solely that of suppressing or modifying the action of genes *A*, *B* and *I*, allowing butein then to appear in the *Y* genotype. The actions of *A*, *B*, and *I* in the petal will presumably be mainly exerted upon processes which, in the leaf, lead to the formation of flavonols and chlorogenic acid (the form in which caffeic acid is usually present in the plant tissues).

At this point it is necessary to consider the differences in structure between the various substances produced by the action of the postulated genes.

The most significant difference between the yellow pigments and all the others is the absence of a substituent hydroxyl group from the position corresponding to 5 in the flavonoid skeleton:



Both the aurone, sulphuretin, and the chalkones, butein and 2′,4,4′-trihydroxychalkone, lack this substituent, and it must be through active inhibition of the oxidation of this carbon atom that the epista of *Y* is expressed.

The specific actions of *A*, *B* and *I* are concern only with oxidations at positions 2, 3, 4 and 3′, sin all the substances affected by them are oxidized positions 5, 7 and 4′. The following equivalenc should be noted: (1) aurones and anthocyanidi are at the same level of oxidation as the correspondi flavones, the equivalent of one oxygen lower th flavonols; (2) chalkones are at the same level oxidation as the corresponding flavanones, th equivalent of one oxygen lower than (1).

The action of the individual genes is seldo absolute. We have observed that there is wi variation between apparently identical phenotyp in the relative amounts of their constituent pigment and while this might be capable of quantitati explanation in terms of the polysomic action of th five postulated genes, *A*, *B*, *Y*, *I* and *H*, it seem more likely that the ultimate result is achieved b competitive action in which physiological (edaphi factors can play a considerable part (cf. the muc lower intensity of anthocyanin pigmentation in lat autumn). It seems worth while noting, howeve that the balance can be shifted between 4′ and 3′,4 hydroxy substituted molecules (cyanidin–pelargon din, eriodictyol–naringenin) and between those mo or less oxidized at position 3 (sulphuretin–butei luteolin–eriodictyol) both dependently and inde pendently. It is worthy of consideration whethe these particular oxidations may be carried out b specific enzymes, the ability of which to act i dependent upon a precise pattern of glycosidatio of the molecules made available as a result of th presence of particular dominant alleles. A hint o the likelihood of this being the case is provided b the report of the presence in *Cosmos sulphureus* of a enzyme capable of oxidizing chalkone to aurone[14] by the ability of phenoloxidases to act on phenoli substrates glycosidically substituted in certain positions, but not on the same substrates substituted i other positions[15]; and by the decolorization b normal green beech leaves of anthocyanins presen in extracts of leaves of the copper beech[16].

We gratefully acknowledge the assistance given b Sir Ronald Fisher and the staff of the Department o Genetics, University of Cambridge, in raising an growing plants; by Mr. W. J. C. Lawrence and Dr. D Lewis, of the John Innes Horticultural Institution for helpful discussion; and by the British Counci and the Agricultural Research Council in providin financial support to one of us (C. G. N.). The wor described in this paper was carried out as part of th programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

## Anode and Cathode Arcs

ARCS which are in general less than one micron in ngth occur at the opening and closing of low-voltage itches. These arcs are initiated and maintained field emission currents. They are of two quite stinct kinds which are most readily distinguished the marks which they leave on polished surfaces.

One type, which we call an anode arc, produces a cular pit on the anode and a general roughening the opposed cathode. Photomicrographs of single ode-type arcs were published[1] before the second pe of arc was discovered. In Fig. 1 is shown the rface of a cathode after the occurrence of a single c of the second type, which we call a cathode arc. he corresponding anode often shows no mark hatsoever.

A feature of the cathode arc is the way in which accentuates scratch lines on an imperfectly polished rface. At high magnification in an electron microope (Fig. 2), each line on the cathode is found to e made up of a large number of single pits, each e result of the explosion of an original roughness field emission current of very high density flowing rough it. Each pit overlaps one of its neighbours, indicating that an arc was moving intermittently along the original scratch.

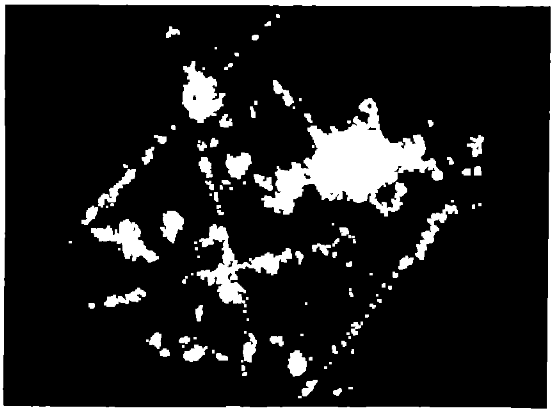

Fig. 1. Photomicrograph of the surface of a polished cathode after a single cathode arc. × 1,200

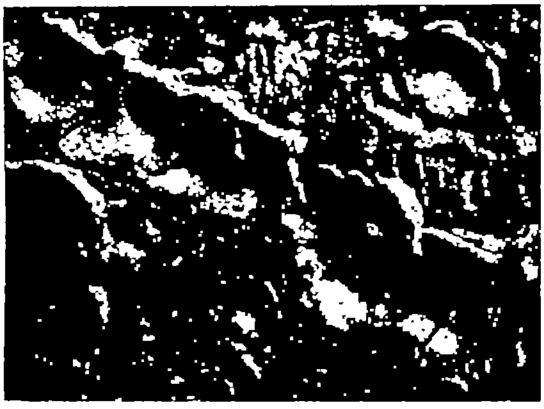

Fig. 2. Electronmicrograph of part of the mark made on a polished cathode by a single cathode arc. × 19,800. Constant current of 4 amp. for 0 45 μsec.

Table 1. CHARACTERISTICS OF ANODE AND CATHODE ARCS (polished palladium electrodes)

| | Anode arcs | Cathode arcs |
|---|---|---|
| 1. Anode appearance | Hole | Nothing or shallow hole |
| 2. Cathode appearance | Roughened | Along scratches |
| 3. Occurrence | | |
| Striking potential > 400 V. | Never | Always |
| Striking potential < 300 V. | Sometimes | Sometimes |
| 4. Arc voltage | 9–12 | 13–18 |
| 5. Striking field | High, $9 \times 10^{6}$ V./cm. | Low, $4 \times 10^{6}$ V./cm. |
| 6. Metal transfer by radioactive tracers | Both directions, net from anode to cathode | Cathode to anode |

Some of the characteristics of the two types of arcs are summarized in Table 1. For palladium electrodes, both cathode and anode arcs occur at striking potentials of 300 V. and lower, with anode arcs favoured by clean surfaces and cathode arcs favoured by dirty surfaces. At 400 V. and higher, only cathode arcs occur. The difference in metal transfer given on line 6 of Table 1 is of importance in understanding the direction and size of the erosion of electrical contacts. It would appear that the confusion associated with erosion measurements in the past is resolved when we identify the type of arc responsible for the erosion.

Experimental details, together with a theory of the mechanisms of the two types of arcs, will appear in a forthcoming paper.

## Neutron Yields from Americium–Beryllium Alloys

THE neutron yields from two americium – beryllium alloys have been measured. The alloys were prepared by the reduction of americium trifluoride with powdered beryllium metal in vacuum, according to the reaction :

$$2\,{}^{241}\mathrm{AmF}_3 + x\mathrm{Be} \rightarrow 2\mathrm{Am}.(x-3)\mathrm{Be} + 3\mathrm{BeF}_2$$

The beryllium fluoride readily distilled, leaving a fluoride-free alloy.

The α-radioactive purity of the americium was > 99·99 per cent. The total inactive impurities were < 0·5 per cent. Americium trifluoride was prepared by fluorinating americium dioxide with a mixture of dry hydrogen fluoride and hydrogen at 650° C. in platinum. The americium trifluoride was mixed with powdered beryllium, 99·8 per cent pure, and heated in a beryllium oxide crucible at a pressure of $5 \times 10^{-5}$ mm. mercury. The chemical reaction was followed by observing neutrons from the nuclear reaction ${}^{9}\mathrm{Be}(\alpha,n){}^{12}\mathrm{C}$ using a boron trifluoride counter connected to a Marconi scaler.

The results of one beryllium reduction of americium trifluoride are illustrated in Fig. 1. A mixture of

Table 1. NEUTRON YIELDS FROM TWO AMERICIUM–BERYLLIUM ALLOYS

| Source | Be : Am atom ratio | Am α-activity | Neutron yield | Neutrons/10 alpha particles* |
|---|---|---|---|---|
| 1 | 263 : 1 | $2 \cdot 97 \pm 0 \cdot 05 \times 10^6$ d./s. | $2 \cdot 13 \pm 0 \cdot 02 \times 10^2$ n./s. | $71 \cdot 7 \pm 1 \cdot 8$ |
| 2 | 14 : 1 | $3 \cdot 24 \pm 0 \cdot 07 \times 10^6$ | $1 \cdot 57 \pm 0 \cdot 02 \times 10^2$ | $48 \cdot 5 \pm 1 \cdot 4$ |

* The limits of error quoted are due to uncertainties in the americium α-activity determi tions and in the comparative neutron measurements. They are subject to a further deviat of ± 5 per cent because of the uncertainty in the absolute neutron yield of the Chalk Ri Ra-α-Be standard.

25·9 mgm. of americium as the trifluoride and 279·8 mgm. of beryllium was weighed into a beryllium oxide crucible. When this loose-packed mixture was in position in the cold furnace, the neutron counting-rate was 3,250 counts/min. The rate of neutron-emission remained unchanged at 675°. When the furnace temperature was raised to 900° the counting-rate increased slowly, indicating that the americium – beryllium alloy was forming. At 1,125° the alloy formation was rapid. After eight minutes a constant counting-rate indicated that the chemical reduction was complete. On raising the furnace temperature to 1,375°, where the alloy was molten, the neutron count increased abruptly to 9,100 counts/min. and remained at this level when the alloy was cooled to room temperature. The resulting shiny ingot weighed 275·0 mgm. A comparison of its γ-activity with that of the reduction apparatus indicated that 5 ± 1 per cent of the initial charge of americium had distilled during the heating period to colder parts of the furnace. The estimated americium content of the ingot from these measurements was 24·6 ± 0·5 mgm. Later, the ingot was dissolved in dilute hydrochloric acid. The total americium α-activity in the solution was $2 \cdot 97 \pm 0 \cdot 05 \times 10^6$ disintegrations/sec., as determined by α-counting aliquots from three independent dilutions. The calculated beryllium – americium atom ratio in the alloy, using Harvey's value[1] of 470 yr. for the half-life of americium-241, was 263 : 1.

A second alloy was prepared at 1,125°, with a beryllium – americium atom ratio of 14 : 1. The product was sintered and crystalline. An X-ray powder diffraction pattern of this alloy served to identify $AmBe_{13}$, an intermetallic compound isostructural with $UBe_{13}$[2] and $NpBe_{13}$[3]. $AmBe_{13}$, beryllium-rich, is face-centred cubic with $a_0 = 10 \cdot 283 \pm 0 \cdot 002$ A. and space group $O_h^6$-*Fm3c*. Since the ratio of γ-intensities of source 1 to source 2 was 1·09 ± 0·01, the americium α-activity in source 2 was estimated at $3 \cdot 24 \pm 0 \cdot 07 \times 10^6$ disintegrations/sec.

The neutron yields from the two alloys were determined by direct comparison against standard $^{227}$Ac-α-Be and Pu-α-Be sources, using a boron t fluoride counter embedded in paraffin. The actiniu and plutonium sources had been calibrated again the Chalk River Ra-α-Be standard and a Nation Bureau of Standards Ra-γ-Be source by activatic of a manganese sulphate solution (Hanna, G. C and Runnalls, O. J. C., unpublished).

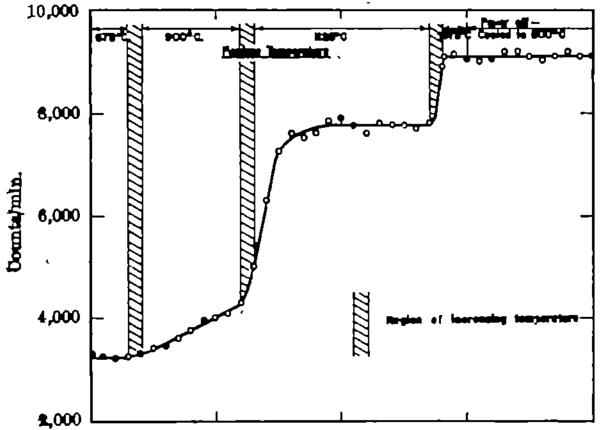

Fig. 1. Measurements of the neutron emission-rate during the conversion of an americium trifluoride – beryllium mixture to a sintered, and eventually molten, americium – beryllium alloy

The neutron yields are indicated in Table 1.

An approximate method for calculating t maximum theoretical neutron yield from these da has been suggested by Dr. A. P. Baerg (private con munication), as follows:

$$\text{Maximum theoretical neutron yield} = n\,\frac{S_{\rm Am}+N.S}{N.S_{\rm Be}}$$

where $n$ is measured neutron yield, $N$ is the rati of beryllium to americium atoms, $S_{\rm Be}$ is atomi stopping power of beryllium (0·63), and $S_{\rm Am}$ atomic stopping power of americium (4·6).

The values quoted for the atomic stopping powe relative to air were obtained by extrapolating know data for α-particles of about 6 MeV. energy[4]. Th calculated maximum theoretical yields were 73·7 an 74 neutrons/$10^6$ α-particles for sources 1 and respectively.

The abrupt increase in neutron yield from source on raising the temperature from 1,125° to 1,375° i attributed to the conversion of solid $AmBe_{13}$-ric aggregates in solid beryllium to a homogeneous liqui solution of americium in beryllium. The precipitatio of americium-rich aggregates would be expecte during the solidification of the molten alloy. Sinc no measurable decrease in the yield of neutrons wa observed, however, when the liquid solidified, th particle size of the aggregates must be small compare to the range of the α-particle.

A detailed report on neutron yields from actinium plutonium, americium and curium alloys will b published later. It should be noted, however, tha the neutron yield for $PuBe_{13}$ measured in the abov manner is 38·7 ± 1·2 neutrons/$10^6$ α-particles. I one assumes that the specific activity of the pluton ium used by Stewart[5] was $1 \cdot 4 \times 10^8$ disintegration min., the neutron yield from her $PuBe_{13}$ sourc was ∼ 40 neutrons/$10^6$ α-particles.

We wish to thank Dr. J. P. Butler, who supplie the americium, and Mr. J. Baird, who prepared th americium trifluoride.

## Neutrons produced in the Bombardment of Beryllium by Deuterons

THE purpose of the present measurements was to btain a thin-target yield-function for neutrons[1] for he $^9$Be$(d,n)^{10}$B reaction from 0·7 to 1·5 MeV. of euteron energy.

The neutrons were detected with two Hornyak uttons, 3 cm. in diameter and 1·5 cm. thick (purhased from Isotope Development, Ltd., London), with a magnesium oxide reflector in a thin aluminium ox, on 6260 *EMI* photomultiplier tubes. A cathode-ollower, a Bell amplifier, an integral discriminator nd a scaler were used. The efficiency for fast neutrons, om 0·5 to 5 MeV., is about 1 per cent; for gamma ays it is very low. The geometry used is shown in ig. 1. The neutron counters were placed as near as ossible, so that the angle of detection was 90° ± 25° with respect to the deuteron beam. A Cockcroft–Walton accelerator with a maximum voltage of ·5 MeV. was used. The beam of deuterons was eflected through 30° by a magnetic analyser. The Be$(p,\gamma)$ reaction was used for calibration.

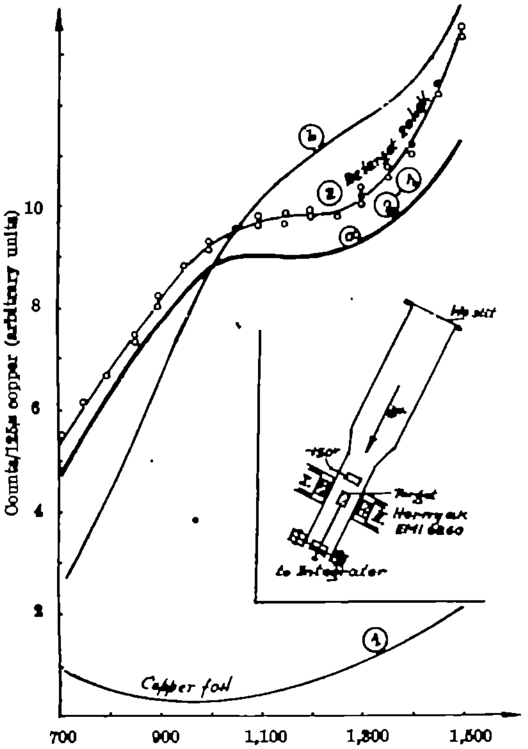

Fig. 1

Bombarding currents were measured by a new current integrator with low impedance input (precision better than 1·0 per cent)[2]. The deuteron beam was collimated with a tungsten foil slit[3]. Beryllium targets, 20–60 keV. thick, were prepared by evaporation of beryllium in high vacuum on to a copper foil of 0·05 mm. thickness. Target thicknesses were determined by weighing on a microbalance. Fig. 1 shows the measured excitation curve (*a*), together with the curve of Evans *et al.*[1] (*b*), taken at 0°. Resonance at 1,000 keV. is indicated by the shape of the curve. The mean values of counts of two detectors were always taken and the curve is a result of many repeated measurements.

Details of this work will be described in the *Bulletin of the Boris Kidrich Institute of Nuclear Sciences*, Belgrade.

## Amplification of 1-cm. Waves in the Helium Negative Glow

IN the course of detailed examination of the attenuation of microwaves in the negative glow of an abnormal discharge in helium, we have observed a negative attenuation. This occurs in a very narrow layer near the beginning of the negative glow and is a function of the gas pressure and the current density in the discharge tube.

A discharge tube 50 cm. long with two aluminium electrodes of 5 cm. diameter contained helium at pressures of 1–3 mm. mercury. A low-powered klystron beamed 1·25-cm. waves at right angles to the discharge tube with the electric vector of the waves parallel to the axis of the tube. The transmitted radiation was detected by means of a crystal detector and a sensitive galvanometer. Changes in attenuation were measured by means of a calibrated precision attenuator. The whole microwave assembly was carefully aligned and could be moved parallel to the discharge tube. The attenuation, because of the discharge, was measured at each position along the discharge tube as the difference in readings of the calibrated attenuator when the discharge was on and off.

Fig. 1 shows the attenuation in db./cm. as a function of the distance *d* from the cathode for a discharge current of 15 m.amp. and a pressure of 2·5 mm. mercury. Near the beginning of the negative

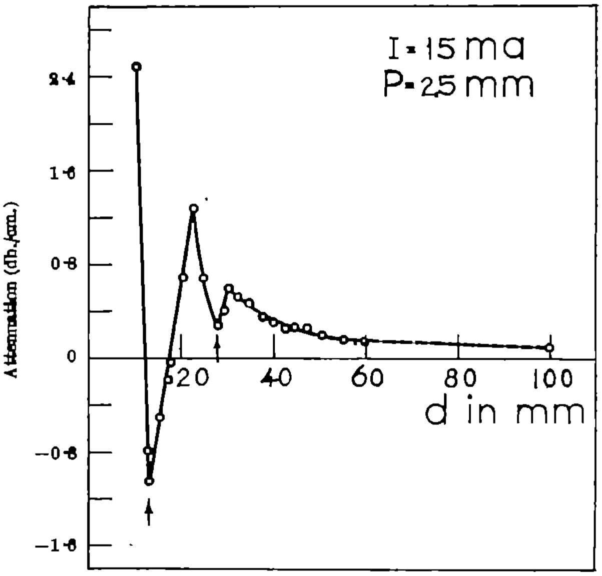

Fig. 1. Attenuation in db./cm. as a function of the distance *d* from the cathode

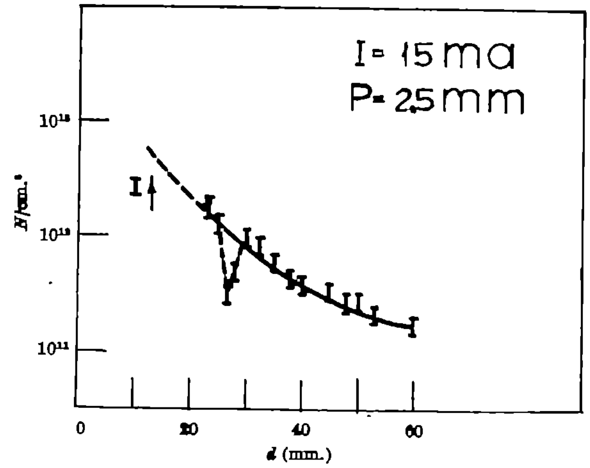

Fig. 2. Electron density as a function of the distance *d* from the cathode, calculated on the basis of a collision-frequency of 2·3 × $10^9$ × gas pressure in mm. mercury

glow, with *d* approximately 13 mm., we observed consistently a negative attenuation, or amplification, of the same wave-length in a very narrow layer. A secondary dip in the attenuation is found at about 27 mm. from the cathode. These changes are unlikely to be due to selective interference or diffraction effects because (*a*) they are independent of the distance of either the sending or receiving antenna from the discharge tube, and (*b*) no such effects are found when the polarity of the voltage is reversed.

If one assumes a collision-frequency of 2·3 × $10^9$ × gas pressure in mm. mercury for helium[1], one can readily calculate the electron density in the negative glow as a function of *d*. This is shown in Fig. 2. The extrapolation of this curve into the region of amplification indicates an electron density *N* of about 7 × $10^{12}$/c.c. at *d* approximately 13 mm. The electron density calculated from the plasma frequency at 1·25 cm. is 7·8 × $10^{12}$/c.c., in close agreement. The secondary dip is at an electron density corresponding to a plasma frequency of about 2·5 cm.

The amplification increases with the current density and with the pressure. The observed amplifications are in very similar regions to the oscillations in narrow sheets observed by Merrill and Webb[2] and other authors[3–5]. Unlike our experiments, these violent oscillatory potentials have been observed in hot-cathode discharges and at frequencies not larger than $10^9$ Mc./sec.

A possible explanation of the mechanism of the amplification is that the plasma oscillations are being excited by means of the impinging radiation. As the radiation passes across the discharge tube, it is being amplified by the longitudinal oscillations. The secondary dip is possibly due to the coupling of a harmonic of the plasn oscillations with the electromagnetic field.

The results of our experiments may have a bearir on the explanation of the propagation of solar an stellar radio waves and possibly on the practic application of amplification of microwaves of cent metre and millimetre wave-lengths.

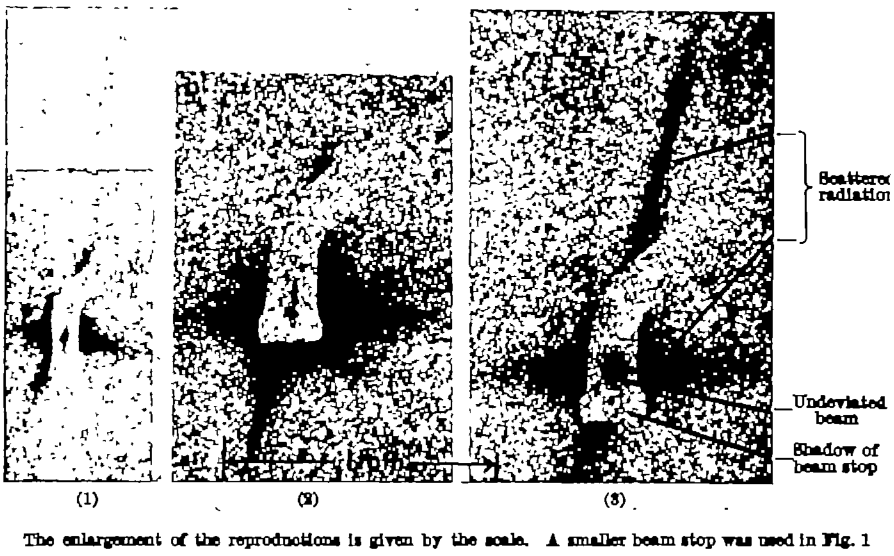
## Investigation of the Fatigue of Metals by X-ray Scattering

It has generally been concluded[1] from previou X-ray studies of the fatigue of metals that th diffraction patterns do not give direct informatio of the fatigue damage.

Some promising results, however, have now bee obtained in an X-ray study of fatigue by a low-angl scattering technique, using the optically focusin camera described by Franks[2]. Individual selecte grains in a polycrystalline copper foil, the orientation of which had been determined by Laue photographs were examined after a preliminary tensile stress an after subsequent amounts of cyclic stressing. Th irradiated area was 100μ × 50μ. The modification in the low-angle scattering patterns from a typica grain are illustrated in the accompanying photo graphs.

The pattern (Fig. 1) after a single tensile stres of 6 tons/in.², equal to the maximum loading i cyclic stressing, shows only a hint of diffractio streaks; but after fatiguing for 1 hr. (3,000 cycles/min and mean stress of 3·2 tons/in.²), two streaks ar readily apparent (Fig. 2). A further 1 hr. of fatigue after which the specimen failed, produced enhance ment of the pattern as shown in Fig. 3.



(1) (2) (3)

The enlargement of the reproductions is given by the scale. A smaller beam stop was used in Fig. 1

The streaks are due to scattering material of anged electron-density within the grain. A tenta-ve interpretation suggests that they are caused by les, their number, size and distribution changing ith differing amount of fatigue. Patterns so far tained suggest that the holes are disk-like in shape, ith a diameter of the order of 100 A. Within the nits of experimental error, the holes lie on those 11} planes on which slip had taken place. It is ggested that the holes result from the plastic formation within the grains caused by cyclic ressing, and that it is these holes which finally glomerate to form a visible crack.

Further experiments are in hand to show whether e information obtained by this technique may be ed as a criterion for estimating fatigue damage.

## Photochemical Processes in Solids at Room Temperature

Although this subject has received little study, he situation of the 'reactive sites' (excited molecules r free radicals) as 'embedded' in the solid matrix may be expected to lead to unusual kinetic effects. The molecular structure and close packing of the matrix should exert a profound effect on the collisional nd energetic interactions of the reactive molecules. Phenomena such as energy transfer and Franck-Rabinowitch recombination should be most efficient n specific cases, although generally this may not be he case. Wilson[1], applying the Laplace transformation technique, has considered recently the interaction f diffusion and reaction kinetics for a series of heoretical cases. We report here some results of ork with nylon polymer films, which have a bearing n this subject.

When thin nylon polymer films (approximately 0μ thick) are irradiated by an unscreened Hanovia .250 *U* mercury arc in the presence of oxygen, a ew absorption band develops centred around 2900 A., which shows the following unusual features, illustrated in Fig. 1. (1) If the incident radiation is cut off and the film stored in the dark, the band continues to increase in intensity with an initial rate greater than that immediately prior to storage. (2) The increase in the band intensity in the dark is found to be a constant fraction of the total intensity change, at all stages of reaction. (3) On re-irradiation the band intensity falls rapidly to a value corresponding to that immediately prior to the dark period; this 2900 A. band is quite clearly resolved and there is no suggestion from the spectra that a different product is formed in the dark from that in the light.

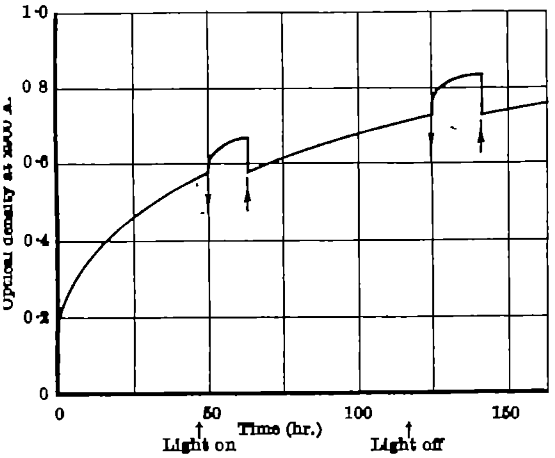

Fig. 1

The following simple reaction scheme can explain this behaviour:

$$\text{Nylon} \xrightarrow[k_1]{h\nu_1} B^{\cdot} + C^{\cdot}\,;\ k_1 I_1 \qquad (1)$$

$$B^{\cdot} + M \xrightarrow[k_2]{} BM\,;\ k_2\,[B^{\cdot}]\,[M] \qquad (2)$$

$$BM \xrightarrow[k_3]{h\nu_2} B^{\cdot} + M\,;\ k_3 I_2\,[BM] \qquad (3)$$

where $I_1$ and $I_2$ are the intensities at frequencies $\nu_1$ and $\nu_2$ respectively, $B^{\cdot}$ and $C^{\cdot}$ are free radicals, $M$ is a molecular species (probably oxygen), and $BM$ the product detected spectroscopically. The kinetics of such a system of consecutive reactions cannot be solved easily unless the simplifying assumption is made that the rate of primary photolysis is much slower than the other reactions involved. The system is then described as being in 'progressive equilibrium', for which the kinetics have recently been considered in some detail (Ford, R. A., unpublished work). In intermittent light a system of this type will show exactly the same characteristics as those found with the nylon films. Further, the kinetics lead to a relationship between rate and light intensity of the following type when $I_1$ and $I_2$ are increased in proportion:

$$\frac{1}{k_1 I_1} = \frac{1}{\mathrm{d}[BM]/\mathrm{d}t} - \frac{\omega}{K k_1}$$

where $\omega$ is $I_2/I_1$ and $K$ is the equilibrium constant for reactions 2 and 3; thus there is a linear relationship between the reciprocal of the rate and the reciprocal of the light intensity, which is confirmed experimentally for the nylon films.

The characterization of the species $BM$ is very difficult because of its instability and very low concentration. However, its sensitivity to light and the evidence of chemical analysis after prolonged irradiation, which shows photo-oxidation has occurred, have led us tentatively to assign the 2900 A. band to a peroxy radical, and therefore species $M$ to the oxygen molecule. The reaction between a doublet organic radical and the $^{3}\Sigma$ ground-state of the oxygen molecule should give a doublet peroxy radical.

The prolonged existence of free radicals in a solid is to be expected, since termination rates will be so slow. Several workers[2] have observed such phenomena. Recently, Porter and Norman[3] have reported work in rigid glasses at 86° K., and Bijl and Rose-Innes[4] in 'Perspex' films at room temperature. Deoxygenated solvents were used for the rigid glass and the temperature was so low that chemical reaction other than photolysis was virtually ruled out. Thus the spectra of the simple free radicals were detected. However, our results suggest that for solids at room temperature rapid diffusion of oxygen will result in only the oxygenated radical being detected. This was probably the case in work by Bijl and Rose-Innes.

It therefore appears that the diffusion processes in solids may be separated kinetically into two classes with rates of a very different order: (1) very slow diffusion of organic free radicals and their oxygenated derivatives; (2) much more rapid gaseous diffusion. The effects described by Wilson[1] appear likely to occur only in the case of the former processes.

If this unusual behaviour in nylon films is due to oxygenated radicals, one would expect it to be a fairly general phenomenon, although it may be unique for solids since a rigid medium is necessary to prevent processes of radical termination. Similar effects have been reported for polystyrene by Reiney *et al.*[5]. But it was then thought that a different product was obtained in the dark from that in the light, and therefore their results were interpreted differently. However, no new band was clearly resolvable in their spectra, which leaves their interpretation open to doubt.

I wish to acknowledge an interesting discussion with Dr. E. J. Bowen, and the permission of British Nylon Spinners, Ltd., to publish this communication.

## A Simplified Method of preparing Pure Mono-, Di- and Tri-glycerides

GLYCERIDES of known structure are usually prepared by blocking one or two hydroxyls of glycerol and esterifying the remaining hydroxyl or hydroxyls with fatty-acid chlorides. Thus monoglycerides are obtained by the action of a fatty-acid chloride on acetone–glycerol according to the well-known method of Fischer *et al.*[1], whereas mixed di- and tri-glycerides have been synthesized by Verkade and co-workers[2] by the use of triphenyl-chloro-methane.

However, the greater reactivity of primary hydroxyls of glycerol, as compared with that of secondary hydroxyl, makes possible a selective esterification without recourse to blocking. This technique has been employed to a limited extent in the past[3]. Selective esterification has now been developed in this laboratory into a general method covering the whole range of glyceride syntheses. One of the difficulties has been to bring into a homogeneous solution glycerol, fatty-acid chlorides and chloroform (used commonly as solvent in such reactions). The difficulty has been overcome by the addition of N,N-dimethyl formamide, which ensures the miscibility of glycerol with other components.

Monoglycerides can now be prepared directly from fatty-acid chlorides and a large excess of glycerol (5–10 mol. of glycerol per 1 mol. of fatty-acid chloride). To obtain monoacid αα′-diglycerides, 1 mol. of glycerol is esterified with 2 mol. of a fatty-acid chloride in a single step. In both cases sufficient dimethyl formamide is employed to obtain a hom geneous mixture at about 10° C., with pyridine catalyst. Diacid diglycerides are produced in th reaction between a monoglyceride and another fatty acid chloride used in approximately equimolar pr portions. By extending this procedure to the pr paration of mixed triglycerides, all three isomers triglyceride containing stearic, palmitic and ole acid radicals have been obtained in good yields b three-stage direct esterification. Their characteristi conformed with those of the triglycerides synthesize by Prof. P. E. Verkade[4], who kindly supplied sampl of his products. Although Fischer's and Verkade methods have been indispensable in establishing th configuration and properties of synthetic glyceride for preparative purposes selective direct esterificatio of glycerol might be useful.

It is hoped to publish experimental details of th work elsewhere.

## Molecular Orbital Theory of the Relative Reactivities of Substituted Aromatic Molecules towards Radical Addition

THE results obtained recently by Farenhorst an Kooyman[1] on the relative reactivities of substitute anthracenes towards radical attack lend support t the validity of the simple molecular orbital theor of radical reactions. The results show (Table 1) tha substitution at the 9-position enhances the activit towards radical attack at the 10-position irrespectiv of the polarity of the substituent group.

Two theoretical criteria have been used for th description of radical reactions: first, the free valenc $F_r$ at atom $r$ in the unperturbed ground-state[2], an secondly the radical localization energy $\Delta E_r$ require to localize a free electron at position $r$, calculate according to the technique introduced by Wheland[3] Now it has been shown[4] that in the simplest molecula orbital theory the change in free valence $\delta F_r$ in passin from a parent alternant hydrocarbon to the mono substituted derivative is an even function of th electronegativity of the substituent group. That i to say, the sign of the change in free valence at an atom of the conjugated molecule is independent o the sign of the electronegativity of the substituen group referred to a conjugated carbon atom. In th present case, the free valence $F_{10}$ at atom 10 increase in passing from the parent hydrocarbon to any of th 9-substituted derivatives of Table 1. Thus the pre

Table 1

| Anthracene | Relative rate-constants for 10-position 55° C. | 70° C |
|---|---|---|
| Unsubstituted | 1·00 | 1·00 |
| 9-Methyl | 2·06 | 2·06 |
| 9-Ethyl | 1·48 | — |
| 9-Cl | 1·64 | 1·62 |
| 9-Br | 1·83 | 1·28 |
| 9-OCH$_3$ | 2·09 | 2·06 |
| 9-CN | 4·24 | 3·94 |

oted increase in free valence is paralleled by the served increase in activity of the 10-position.

Similarly, it has been shown[3] that the change in calization energy $\Delta E_r$ in passing from the parent drocarbon to the monosubstituted derivative is so an even function of the electronegativity of the bstituent group. In the present case, the localization ergy $\Delta E_{10}$ at atom 10 is reduced in passing from e parent hydrocarbon to all 9-substituted deriva- ves. Again, the observed increased activity at the )-position parallels the predicted reduced activation ergy.

To emphasize the significance of these results, it ay be pointed out that, for example, the charge nsity $q_{10}$ (which is used as an index for ionic activity) at atom 10 would increase for 9-sub- ituents less electronegative than carbon and crease for those more electronegative. Similarly, e localization energy for electrophilic attack at e 10-position would decrease for 9-substituents ss electronegative than carbon and increase for ose more electronegative. These quantities are, fact, odd functions of the electronegativity at the sition of substitution[4,5]. It may be noted that e dependence upon electronegativity in the treat- ent described here is deduced analytically, and e result is free from the usual arbitrary choice of arameter.

The new experimental results bear out the earlier ork of Hey and Williams[6] on radical attack upon nzene derivatives, which also support the simple olecular orbital theory in that the effect of various ibstituent groups is independent of their polarity. here exists, however, one interesting anomaly. The mple theory predicts an increase in free valence at e *ortho*- and *para*-positions and a decrease at the *eta*-position for all substituents[3]. Hey and Williams ave found, however, that all three positions are tivated, except in the case of pyridine, which mani- sted an increased relative rate factor in the α- and -positions and a decreased value in the β-position. here are good reasons for believing that the simple eory, which represents the effect of a substituent y a change of coulomb integral at the position to hich it is attached, reproduces adequately the erturbation produced in the charge distribution at ositions for which the effect is not small, provided ectron-attracting groups are represented by an crease in electronegativity, and electron-donating y a decrease, at the position of attachment. The gns of the changes in charge density and free alence, indeed, are then correctly represented mpublished calculations). The changes produced t the meta-position are, however, always small, and ere the simple theory is generally not adequate. ut for the particular case of pyridine, the hetero tom N is coincident with the position of substitution nd the simple theory is strictly valid. It is interesting o note that in this case[6] the β(*meta*)-position is, in ct, deactivated, as predicted by the theory.

## Adsorption of Methylene Blue by High-Silica Sands

HIGH-SILICA sands from which the intergranular material has been washed away have been found to adsorb considerably more methylene blue per unit of superficial surface as determined by the air permeability method[1] than was adsorbed by crushed quartz crystal. A sample of the latter material (from B.D.H.) took up $1 \cdot 2 \times 10^{-4}$ mgm. of dye per sq. cm. superficial surface, and this figure agrees well enough with that calculated by Gaudin and Rizo Patrón[2] for the adsorptive capacity of a quartz surface for positive ions to suggest that the surface accessible to methylene blue was very nearly the same in extent as the superficial surface for this material. The same was not true of most sand samples. Values for the surface accessible to methylene blue calculated from the figure obtained for crystal quartz were found in some instances to be many times the superficial surface.

Sixty-five samples from forty-five localities, eight of them outside the British Isles, have been examined. Forty-eight of the samples had values of between 2 and 5 for the ratio superficial to accessible surface, eleven had ratios greater than 5, and the remainder had ratios less than 2. The extreme range was about 0·5–15·9.

From the following evidence the adsorptive layer seems to consist of finely divided silica, that is, the grain surfaces are involuted to a greater or lesser extent. (1) 40 per cent hydrofluoric acid reduced the adsorptive capacity to a very low figure, and a marked reduction was effected by solutions containing as little as 0·1 per cent hydrogen fluoride. (2) *N* sodium hydroxide reduced the adsorptive capacity of all but one of the samples examined; subsequent washing with dilute acid to remove any adsorbed sodium ions did not increase the adsorption of dye. (3) Attrition and comminution reduced the ratio of superficial to accessible surface. (4) Sand coated artificially with $Fe_2O_3$ or $Cr_2O_3$ adsorbed very little methylene blue.

That the adsorptive layer did not consist of silicic acid[4] or hydrated silica seems to be proved by the behaviour of the sands on ignition at 700° C. Nineteen samples were ignited, and of these, eleven showed reduction in adsorptive capacity (which could be attributed to sintering of surface impurities), three were unchanged, and five adsorbed more dye than previously.

Sands which were strongly stained with iron generally adsorbed most dye, and rather surprisingly the adsorptive capacity was not increased by extraction with 11 *N* hydrochloric acid, except in a few cases. Of twenty-six samples extracted, only four adsorbed more dye after treatment, fourteen adsorbed less, and the remainder were unchanged. Most of the sands carried $Fe_2O_3$ or $Al_2O_3$ on the surface of the silica grains. $Al_2O_3$ was detected, on the paler sands, by the pink colour obtained with aurine tricarboxylate[5].

It does not seem possible to account for the reduction in adsorptive capacity after acid treatment by assuming that hydrogen ions were taken up from the acid solution and so prevented subsequent adsorption of methylene blue[6]. Samples which had been extracted with hydrochloric acid and then ignited at 500° C. showed no regular change in adsorptive capacity. Of eight samples so treated, two showed a slight increase, two were unchanged, two showed a slight decrease, and two showed a marked decrease. It seems reasonable to suppose that adsorbed hydrogen ions would be driven off below 500° C., with a consequent increase in adsorptive capacity for methylene blue.

We are led to conclude that the observation that acid extraction does not in general lead to increased dye adsorption must be accounted for by the inaccessibility to methylene blue ions of the sites occupied by the basic compounds on the silica surface. The reduction in adsorptive capacity observed in many cases may arise from disruption of capillaries adjacent to the positions occupied by the basic compounds, or of capillaries of which these latter form structural units, leading to a general 'smoothing out' of the surface.

## Radioactivation Analysis of Phosphorus in Silicon

In a previous communication[1], a radioactivation method for the determination of arsenic in 'high purity' silicon was outlined. Further work on trace impurities in this element has resulted in the development of a technique for estimating submicrogram quantities of phosphorus.

On irradiating a silicon sample with thermal neutrons, the following reactions take place.

$$^{30}\mathrm{Si}\ (n\gamma)\ ^{31}\mathrm{Si} \xrightarrow{\beta'} {}^{31}\mathrm{P} \quad t_{1/2} = 2\cdot 62 \text{ hr.} \qquad (1)$$

$$^{31}\mathrm{P}\ (n\gamma)\ ^{32}\mathrm{P} \xrightarrow{\beta'} {}^{32}\mathrm{S} \quad t_{1/2} = 14\cdot 3 \text{ days} \qquad (2)$$

It can be seen that phosphorus atoms are produced by the decay of silicon-31 and that these are then activated according to equation (2). As these phosphorus-31 atoms are produced exponentially during irradiation, they are subjected to varying irradiation times and so the activity they produce, when extrapolated to zero time, merely indicates an apparent phosphorus concentration. The following expression has been derived for this concentration:

$$C_{\mathrm{app}} = \frac{6\varphi\sigma T\times 10^{6}}{0\cdot 69\ N}\left\{\frac{0\cdot 69\ T_i}{(1-\exp -0\cdot 69\ T_i/T)T} - 1\right\}$$

in parts per million (3)

where $\varphi$ is neutron flux, $\sigma$ is cross-section of silicon-30 (barns), $T$ is half-life of phosphorus-32 (sec.), $T_i$ is irradiation time (sec.), and $N$ is Avogadro's number.

The above relationship indicates that the apparent phosphorus concentration varies as the neutron flux and irradiation time, so that irradiation conditions for phosphorus in the submicrogram range must be carefully chosen to give optimum analytical conditions. We have selected an irradiation time of one week at a pile factor of ten for routine determinations, when equation (3) gives 0·0011 p.p.m. of apparent phosphorus, although under these conditions th total phosphorus-31 impurity introduced into silic by radioactivation is 0·0024 p.p.m. ($4\cdot 7 \times 1$ atoms/gm. silicon).

We have used the following method for separatin the active phosphorus chemically. Sufficient time allowed to elapse after irradiation for the silicon- activity to have decayed to a negligible amount (c to two days for a sample of 0·5–1 gm.). The silic is slowly dissolved in a hydrofluoric–nitric acid mi ture with disodium hydrogen phosphate present carrier, the rate of reaction being controlled b addition of nitric acid. After complete removal the silicon as the gaseous silicon tetrafluoride, th solution is reduced to small bulk, perchloric acid added and taken to fuming to remove hydroge fluoride. Dilute hydrochloric acid is added to th solution and the phosphate present is precipitate as $MgNH_4PO_4.6H_2O$ with magnesia mixture an ammonia in the usual way[2]. After standing for 24 h the precipitate is filtered, washed and redissolved wit dilute hydrochloric acid. The magnesium ammoniu phosphate is again brought down as before but i the presence of citric acid, and the whole is allowe to stand for a further 24 hr. It is then centrifuge washed and slurried into a crucible and ignited 1,100° C. to constant weight. The $Mg_2P_2O_7$ thu formed is finely ground and transferred to a countin tray to be counted and weighed.

Red phosphorus and disodium hydrogen phospha were tried as standards. Known amounts were seale in silica ampoules and irradiated with the silico samples. They were dissolved and the phospha extracted as already described. Although agreeme was obtained between the two standards, disodiu hydrogen phosphate was selected as the more sui able due to its higher purity and to the ease wit which it could be dissolved.

Samples of 'pure' silicon from various sources, fo use in semi-conductor devices, have been examine by this technique and found to contain phosphoru impurity ranging from 2·0 to 0·004 p.p.m. Th distribution of phosphorus within a 'doped' singl crystal has also been investigated by this metho and the results obtained are consistent with publishe segregation coefficients[3], conductivity and aut radiographic measurements.

We wish to acknowledge helpful discussions wit colleagues in this Laboratory, especially Mr. R. H. A Crawley.

## Alpha-Oxidation of Omega-(2 : 4-Dichlorophenoxy)alkanenitriles and 3-Indolylacetonitrile within Plant Tissues

BIOLOGICAL and chemical investigations carried ou here on the plant growth-regulating activity ω-aryloxyalkanecarboxylic acids have established th importance of β-oxidation as a mechanism by whic these acids are degraded in plants[1]. As a logic extension of this work, the corresponding nitriles we pared and examined in the wheat cylinder ngation test (Table 1, Fig. 1) and pea curvature t (Table 1). Extracts of the wheat and pea tissues d of the solutions used in these tests were then parately examined by paper chromatography in the scending manner using butanol/ammonia/water 00 : 6 : 36 at 20° C.). The chromatograms were vided transversely into ten equal segments and ch was assayed for growth-regulating activity by e wheat test. Authentic 2 : 4-dichlorophenoxy etic acid was also run in each experiment. By ch means it was possible to correlate activity of the bstance originally tested with the production of e dichlorophenoxyacetic acid, a compound highly tive in the wheat cylinder test. In every instance ere growth-regulating activity was shown, chromographic evidence for degradation of the compound 2 : 4-dichlorophenoxyacetic acid was obtained. us, when the homologous series of acids used in ese experiments ($RO(CH_2)_nCOOH$) was treated th both wheat and pea tissue, an alternation in tivity associated with β-oxidation[1] was accom nied by the appearance of 2 : 4-dichlorophenoxy etic acid when *n* was 1, 3 and 5.

The nitrile series, $RO(CH_2)_nCN$, however, behaved ite differently. Thus, in the pea test, only 2 : 4-di lorophenoxyacetonitrile ($n = 1$) was active and as correlated with the production of the correspond g acid. No activity was shown in the pea test by y of the higher homologues, and this was in agree ent with the fact that no 2 : 4-dichlorophenoxyacetic id was found in solutions of these compounds eated with pea tissue. In view of the inactivity of ose members where *n* is 3 or 5, it would seem that e —CN → —COOH conversion does not readily cur in these higher nitriles in presence of pea sue.

In the wheat cylinder test, all members of the trile series showed significant activity (Fig. 1), and : 4-dichlorophenoxyacetic acid was produced in all ses in amounts corresponding to their activities. id production is readily explicable in the alternate mologues ($n = 1$, 3 and 5) in terms of hydrolysis llowed by β-oxidation; but the production of the id from other members of the nitrile series ($n = 2$, 4 d 6) must involve a type of side-chain breakdown t hitherto recognized in plant biochemistry. The fact that β-(2 : 4-dichlorophenoxy)propionitrile ($n = 2$) is partially converted to 2 : 4-dichlorophenoxyacetic acid shows that a one-carbon fragment can be lost. A similar degradation in the other nitrile homologues with $n = 4$ and 6, followed by β-oxidation, would explain the production of the 2 : 4-dichlorophenoxyacetic acid in these cases.

Table 1. GROWTH-REGULATING ACTIVITY IN TWO TESTS OF ω-(2 : 4-DICHLOROPHENOXY)ALKANE-CARBOXYLIC ACIDS, $RO(CH_2)_nCOOH$, AND NITRILES, $RO(CH_2)_nCN$

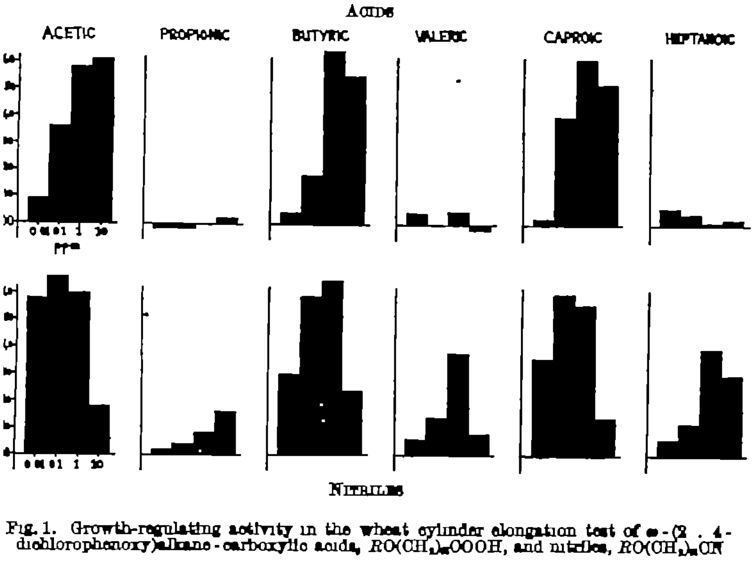

Fig. 1. Growth-regulating activity in the wheat cylinder elongation test of ω-(2 : 4-dichlorophenoxy)alkane-carboxylic acids, $RO(CH_2)_nCOOH$, and nitriles, $RO(CH_2)_nCN$

In a parallel investigation we have studied the breakdown of 3-indolylacetonitrile within pea and wheat tissue using similar chromatographic techniques. The negligible activity of this compound in the pea test was consistent with the absence of 3-indolylacetic acid on the chromatogram, a result in agreement with the work of Thimann[2]. On the other hand, it was readily detected on the chromatogram from the wheat cylinder test, in which the nitrile was highly active. The presence of 3-indolylacetic acid was proved by its $R_F$ value, bioassay, and the production of distinctive colours with Ehrlich and other reagents. In all experiments where pea or wheat tissues were treated with the nitrile, however, the chromatogram showed a distinct red spot of $R_F = 0{\cdot}12$ when sprayed with Ehrlich reagent followed by concentrated hydrochloric acid. This new compound was shown to be an acidic substance, inactive in both the wheat and pea tests, and it possessed the same $R_F$ values (0·12 in butanol/ammonia/water; 0·20 in isopropanol/ammonia/water) as 3-indolylcarboxylic acid. When run mixed with an authentic specimen of this substance, a single spot was obtained. Further evidence of its identity was provided by ultra-violet absorption spectra measurements kindly carried out for us by Prof. E. A. Braude.

In view of the above findings, it was reasonable to expect 3-indolylcarboxylic acid to be present in some of the plant tissues where the acetonitrile occurs naturally. Other chromatographic studies carried out here by Dr. P. M. Cartwright have, in fact, revealed that 3-indolylcarboxylic acid is present with a substance suspected to be 3-indolylacetonitrile in germinating peas.

The conversion of 3-indolylacetonitrile to 3-indolylcarboxylic acid in pea and wheat tissue represents a similar type of degradation, $—CH_2CN \rightarrow —COOH$, to that indicated in the phenoxy nitrile experiments discussed above. In both cases the loss of a one-carbon fragment occurs. Since the α-methylene group becomes converted to carboxyl, the process may be regarded as one of α-oxidation. Various mechanisms by which such conversions may take place are now being studied. The results of preliminary experiments on the behaviour of the corresponding amides both in the phenoxy and indole series indicate that the amide is not an important intermediate product in such α-oxidation.

The possibility that aliphatic nitriles may be metabolized in the animal body by a mechanism involving oxidation of the α-methylene group arises from the work of Lang[3] and Adeline[4]. More recent work of Pattison[5] on the toxicity to rats of ω-fluoroalkylnitriles provides further evidence of such breakdown. Thus, in the animal there is evidence that certain nitriles may be metabolized by a process of α-oxidation followed by β-oxidation of the resulting acid. The present work indicates that a similar sequence of breakdown reactions may occur in plant biochemistry.

These results will be published in detail elsewhere.

## Inhibition, Restoration and Enhancement of Proteolytic Action by Polylysine and Polyglutamic Acid

POLYELECTROLYTES of high molecular weight have been shown to inhibit a variety of enzymes in what Spensley and Rogers[1] have called macroanionic and macrocationic inhibition. This phenomenon is probably due to an interaction of the polyelectrolytes with the enzyme or the enzyme-substrate complex. The inhibition of pepsin by the polypeptide polyelectrolyte poly-L-lysine has been reported by Katchalski, Berger and Neumann[2]. Polylysine has been shown to combine reversibly with albumin to form insoluble complexes which dissolve in the presence of excess of either component[3]. We have also studied the inhibition of the proteolytic action of pepsin by the macrocation, poly-L-lysine, and the reversal of this inhibition by excess polylysine, and the inhibition of trypsin by the macroanion, polyglutamic acid, as well as the restoration and enhancement of trypsin action by excess polyglutamic acid.

Poly-L-lysine (average molecular weight 2,100) was added to pepsin (25γ per ml.) in 0·001 *M* acetate buffer at *p*H 4·7 and the per cent transmittance of the solution was determined at 400μ. The complex was then added to the substrate and peptic activity determined by the method of Anson[4]. The results obtained from these experiments are shown in Table 1.

Table 1. EFFECT OF POLY-L-LYSINE ON PEPSIN

| Concentration of poly-L-lysine (γ per ml.) | Mole ratio of poly-L-lysine to pepsin | Transmittance (per cent) | Inhibitio (per cent |
|---|---|---|---|
| 0 | — | 100 | 0 |
| 1·56 | 1 | 98 | 0 |
| 2·1 | 1·5 | 56 | 0 |
| 3·12 | 2·2 | 77 | 13 |
| 6·25 | 4·4 | 98 | 100 |
| 12·5 | 8·8 | 99 | 100 |
| 25 | 17·5 | 99 | 98·5 |
| 50 | 35 | 99 | 46·5 |
| 100 | 72·5 | 100 | 29·5 |
| 200 | 150 | 100 | 2·4 |

Poly-L-lysine was observed to inhibit pepsin completely at low concentrations, but at higher concentrations of the peptide, 98 per cent of the original
enzymatic activity was restored. At the same tim
it was observed that polylysine and pepsin form
insoluble complexes at low concentrations of t
polyelectrolyte, which dissolved when the concentr
tion of the peptide was increased. Addition of t
peptide to the substrate rather than to the enzy
did not inhibit the proteolytic activity of pepsin.

The inhibition of trypsin (100γ per ml.) by t
macroanion, polyglutamic acid (average molecul
weight 2,580), was carried out in much the san
manner as the inhibition of pepsin by poly-L-lysi
except that phosphate buffer 0·005 *M* at *p*H 7·5 w
used. The per cent transmittance of the solution w
again determined at 400μ, and the tryptic activi
was followed by the method of Anson[4]. Polyglutam
acid was found to inhibit the proteolytic action
trypsin at low concentrations, whereas at higher co
centrations of this peptide the activity was not on
restored but also greatly increased. At the highe
concentration of peptide used, a molecular ratio of
to 1, the activity of trypsin was increased almo
three-fold. An insoluble complex was shown to for
at low concentrations of polyglutamic acid; th
precipitate dissolved when the concentration of t
peptide was increased. A summary of the resul
obtained is shown in Table 2.

The inhibition of the two enzymes is similar, a
it is probable that a common mechanism exists f
both cases. At low concentrations of the peptid
the enzyme and the peptide must combine, probab
due to electrostatic attraction, to form complex
which aggregate to give the precipitates. Inhibiti
may then be due to either the masking of the acti
site of the enzyme or the precipitation of the enzym
When the concentration of the peptide is increase
the complex dissolves and enzymatic activity
restored. The mechanism for the enhanced proteolyt
action of trypsin by polyglutamic acid is unknow
It may be due to the action of the added ion
charges on the soluble polyglutamic acid – trypsi
complex in increasing the rate of combination wi
the substrate.

This communication is published with the approv
of the Director of the Wisconsin Agricultural Expe

## ffect of 2,4-Dichlorophenoxyacetic Acid and Maleic Hydrazide on Potato Proteins as shown by Paper Electrophoresis

PREVIOUS studies[1] have shown that 2,4-dichloro-henoxyacetic acid increases the total protein content potato tubers and that maleic hydrazide upsets ll-division in the meristematic zone in tuber eyes[2]. he present work was concerned with changes in otato tuber proteins, resulting from plant spray eatments with 2,4-dichlorophenoxyacetic acid ,4-D), maleic hydrazide, and a combination of the vo chemicals. Analyses were made immediately after arvest and after sixty days storage.

Potatoes used in this experiment were of the Red IcClure variety, grown at the San Luis Valley xperimental Farm near Center, Colorado, during e 1953 season. There were four plots, each replicated ree times. Treatments were as follows: (1) maleic ydrazide (*MH*–40, U.S. Rubber Co.) at 3 lb. per re active ingredient; (2) alkanolamine salts thanol and *iso*propyl series) of 2,4-dichlorophenoxy-etic acid (Dow Chemical Co.) at 0·5 lb. per acre, nd equivalent; (3) alkanolamine salt of 2,4-di-lorophenoxyacetic acid at 0·5 lb. per acre plus aleic hydrazide (*MH*–40) at 3 lb. per acre sprayed hr. apart in that order; (4) control, no treatment. The treatments were applied as plant sprays when e tubers were about ½ in. in diameter. At harvest, ibers were selected at random from each treatment id frozen. Comparable samples were stored for xty days in a potato cellar (average temperature )° F.), after which they were also frozen. The tubers from each sample were allowed to thaw and the juice was concentrated to one-fifth its original volume by lyophilization.

(*B*) Untreated sample after 60 days of storage. (*C*,1) Sample treated with 2,4-D; at harvest. (*C*,2) Untreated sample at harvest. (*D*,1) Sample treated with 2,4-*D*, after 60 days storage. (*D*,2) Untreated sample after 60 days storage

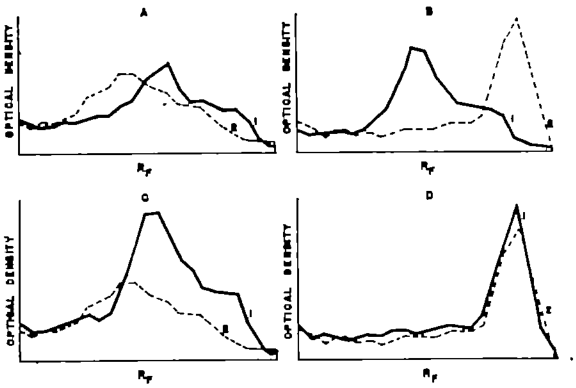

Fig. 2 Optical density curves showing the protein fractions in Red McClure potato juice. (*A*,1) Sample treated with maleic hydrazide at harvest. (*A*,2) Untreated sample at harvest. (*B*,1) Sample treated with maleic hydrazide; after 60 days storage. (*B*,2) Untreated sample after 60 days storage. (*C*,1) Sample treated with maleic hydrazide and 2,4-D at harvest. (*C*,2) Untreated sample at harvest. (*D*,1) Sample treated with maleic hydrazide and 2,4-D; after 60 days storage. (*D*,2) Untreated sample after 60 days storage

A Wieland-type of instrument modified by Grassmann and Hannig[3] was used for producing zone electrophorograms. Cacodylic buffer of *p*H 6·93 (above the isoelectric point of the potato protein) was used in the instrument. The ionic strength was 0·1. A 0·02-ml. aliquot of concentrated juice was pipetted on a buffer-dampened filter-paper strip (Whatman No. 1), 1½ in. wide. The instrument was run for six hours at 300 V., 5 m.amp., after which the paper strips were taken out and dyed in amido-black 10*B* (Farbenfabriken Bayer, Leverkusen, Germany) for 10 min. Upon coming out of this bath, the strips are dyed a dark colour. Three 10-min. baths of 5 per cent phenol were used to de-stain the strips of paper, followed by fixation in 10 per cent concentrated glacial acetic acid in absolute methanol.

The relative amounts of proteins in the tuber juices were measured by a densitometer (Welch and Co., 'Densichron') using the electrophorograms. Since the amido-black stains proteins proportionately to the concentration, the optical density curves were plotted for each treatment. The total area (proteins) under the curves was measured with a planimeter in square inches.

A typical optical density curve for each of the four treatments is shown in Figs. 1 and 2. The dotted line in all cases represents the untreated samples. Six probable protein fractions appeared in the electrophorograms of the untreated samples (Fig. 1,*A*). After sixty days of storage (Fig. 1,*B*) the main protein fraction decreased and the fastest-travelling fraction increased. Groot *et al.*[4], using a Tiselius electrophoretic apparatus, showed there were two protein fractions in potato juice. The main fraction was a globulin known as tuberin and a second fraction was called tuberinin. A third fraction was suggested but was not named. In 1953, Schwarze[5] used paper electrophoresis and obtained one large and four smaller bands, a total of five different protein fractions. Fig. 1,*A* shows six fractions. The sixth one is probably the unnamed protein suggested by Groot, and may be part of the wide band shown by Schwarze. A similar change occurred at harvest in the samples treated with 2,4-dichlorophenoxyacetic acid (Fig. 1,*C*) and after storage (Fig. 1,*D*). Maleic

| Treatments | Total protein | | |
|---|---|---|---|
| | Rate/acre (lb.) | At harvest (area units, sq in.) | After 60 days storage (area units, sq. in.) |
| (1) Maleic hydrazide* | 3 0 | 2 61‡ | 1·66 |
| (2) 2,4-D† | 0·5 | 2 68 | 2·71 |
| (3) Maleic hydrazide + 2,4-D | 3·0 + 0·5 | 3·23 | 2 26 |
| (4) Control, no treatment | none | 2·10 | 2 28 |

* As *MH*-40, the sodium salt, active ingredient.
† As alkanolamine salt, active ingredient.
‡ Planimeter measurements of areas under density curves; each value is the mean of six different samples.

hydrazide produced very little change at harvest (Fig. 2,*A*) but appeared to prevent the shift after storage (Fig. 2,*B*) which occurred in the controls. This failure to change in the maleic hydrazide samples may be the basic reason why maleic hydrazine prevents sprouting, whereas 2,4-dichlorophenoxyacetic acid (at 0·5 lb. per acre) does not prevent sprouting in potatoes. Combination effects (Fig. 2,*C* and *D*) resembled those of 2,4-dichlorophenoxyacetic acid used alone.

The relative amount of proteins in the tuber juice, as measured by the areas under the optical density curves, is shown in Table 1.

The results indicate that all three treatments increased the total protein in potato tubers, as compared to the untreated sample, based on protein analysis immediately after harvest. The greatest increase resulted from the combination treatment. After sixty days of storage, the maleic hydrazide decreased, and the 2,4-dichlorophenoxyacetic acid increased, the total protein as compared to the control. The combination treatment produced little change on the total protein. As indicated in an earlier paper[1], this study has further substantiated the fact that treatment of Red McClure potato plants prior to harvest with 2,4-dichlorophenoxyacetic acid increases the protein content of the tubers.

## Growth of Sarcoma 37 Mouse Ascites Tumour in Peritoneal Fat

THERE are no previous reports that ascites tumours grow in or on tissues before fluid and cells increase in the peritoneal cavity. Therefore, it is thought to be of interest to present evidence that such growth takes place in peritoneal fatty tissue.

In early passages of a sarcoma 37 mouse ascites tumour, histological sections invariably showed sarcomatous infiltration of peritoneal fatty tissue. Afterwards similar infiltration was revealed befo ascitic fluid had accumulated. As a result of the findings an experiment was carried out in whi 3·1 million sarcoma cells were inoculated int peritoneally into male mice that were killed intervals after inoculation. The peritoneal fluid w collected and measured; if the amount was less th 0·1 ml. it was recorded as such. The sarcoma ce in the fluid were counted in a hæmocytometer ar recorded in millions per ml. From these results tl total number of sarcoma cells in each peritoneal flu was estimated. Histological sections were prepar from the fatty tissue in the peritoneum between tl stomach and spleen and from the bodies of f attached to the gonads. The results are shown Table 1.

Table 1. Increase of Sarcoma Cells and of Fluid in the Pe toneal Cavity and Infiltration of Peritoneal Fat aft Intraperitoneal Inoculation of Male Mice with 3·1 Milli Sarcoma Cells

| Time after inoculation in hr. | No. of mice | No. of mice with 0·1 ml. or more of fluid | Total sarcoma cells in millions | No. of mic showing sarcoma cells in fa |
|---|---|---|---|---|
| 6–10 | 5 | 0 | Av. < 2·9<br>Range < 2·4 to < 3·5 | 5 |
| 18–22 | 4 | 0 | Av. < 2·5<br>Range < 2·2 to < 3·0 | 4 |
| 30–48 | 6 | 2 | Av. < 6·8<br>Range < 3·6 to 11·6 | 6 |
| 72 | 3 | 3 | Av. 11·2<br>Range 9·6 to 12·1 | 3 |

It can be seen that during the first twenty-tw hours there is no significant increase in the numb of cells over those inoculated and no accumulatio of peritoneal fluid. During the first period (6–10 hr it was necessary to examine many sections from eac mouse; but, in some sections from each, sarcom cells could be recognized within the fatty tissue itse by their very large size, basophilic cytoplasm an large vesicular nucleus. Some cells could be see applied to blood vessels, some to fat cells and son were in mitosis. In sections removed from mi killed between 18 hr. to 22 hr., sarcoma cells we more numerous, sometimes occurring in groups r placing fat cells. Between 30 hr. and 48 hr. the appeared to be an increase in the total number cells in the peritoneal fluid, and two of the si mice had more than 0·1 ml. of fluid. Sections showe that groups of sarcoma cells were in the fatt tissue and small vascular sheets of them replace fat cells. At 72 hr. there was a definite increase i sarcoma cells in the fluid, and three of three mi had excess fluid. Sections showed vascular shee of sarcoma replacing relatively large areas of fatt tissue.

These results show that invasion and multiplicatic of sarcoma 37 cells takes place in peritoneal fatt tissue before there is an increase of cells or fluid in tl peritoneal cavity. This suggests that intraperitoneall inoculated sarcoma cells invade fatty tissue, whe they can obtain nutriment for multiplication fro nearby blood vessels.

These findings permit the explanation that th ascites tumour grows initially in fatty tissue an when growth is sufficiently advanced, cells pass in the peritoneal cavity. If this is the mechanism growth of this tumour, the hypothesis that the cel multiply actively while freely suspended in periton fluid remains to be proved.

I am indebted to Dr. Franks, Banting Institute, ronto, for the sarcoma 37 and to Hansi Kroeker d Miss Melville and staff for technical assistance. e work was supported by a grant from the National ncer Institute of Canada.

## A Proprioceptor in the Body Musculature of Lepidoptera

DURING a study of muscle histolysis in saturniid ths[1], sense organs were found in association with intersegmental muscles. So far as we can ascer- n, they are of a type not previously described for ects. They resemble the receptors discovered by exandrowicz[2] in the Crustacea. Each receptor con- ts of a modified muscle fibre in which the striations faint, but which is capable of contraction. In final instar larva of *Antheraea pernyi*, there is a ir of these receptors in the meso- and meta-thorax d in abdominal segments 1–9. The receptors lie the dorsal longitudinal muscles[1] and are attached the epidermis at the intersegmental folds. They rsist during metamorphosis and are present in the domen of the pupa and adult, but so far they have t been located in the thorax of these stages. Near middle of the fibre, a swelling is formed by an oid sac filled with an unidentified substance which ins with some nuclear stains such as hæmatoxylin d celestin blue. Attached to the receptor at this int is a single large sensory neurone the dendrites which enter a fibre tract running the full length the receptor. The fibre tract appears to be com- sed of connective tissue fibres. A rich motor ervation is present, with nerve endings at intervals along the organ. Similar receptors have been found *Platysamia cecropia*, *Telea polyphemus*, *Samia lkeri* and *Actias selene*.

The function of the receptors of the pupa of *pernyi* has been investigated oscillographically. ter exposure of a single receptor with a suitable gth of nerve, a strip of cuticle bearing the receptor removed from the pupa. Flaps of cuticle from the ghbouring segments are left at either end of the paration. These flaps are clamped in an apparatus signed for stretching and relaxing the receptor. It nsists of a 'Perspex' trough with a fixed clamp for end of the cuticle strip and an adjustable clamp the other end. The adjustable clamp is attached a metal rod which can be locked when the prepara- n is in a suitable position. The bracket for the l is in turn attached to a solenoid which causes the l and clamp to flick to and fro in the direction of longitudinal axis of the preparation. The amount stretching and relaxation thus imposed on the eptor is controlled by micrometer screws. Through- t the experiments the preparation is immersed in ect Ringer's solution[3].

A regular single unit impulse discharge can be orded from this preparation. The duration of pulse is approximately 5 msec. at room tempera- e, and the discharge frequency depends on the sion. Frequencies of about 30 impulses/sec. are nmonly found when the preparation is set up with nimum of tension. The discharge activity con- ues unaltered for an hour and longer. Stretching the preparation evokes an immediate increase in the discharge frequency, and the higher level of activity is maintained while the stretch lasts. There is a certain amount of adaptation; but the time course of the adaptation is very slow. After cessation of stretch, there is a marked post-stimulatory depression followed by a gradual return of the impulse activity to the initial discharge frequency.

The presence in insects of proprioceptor organs closely resembling both in structure and in mode of function[4] those recently discovered in Crustacea appears to be of considerable interest. A detailed study of the histological structure of the organ and of the quantitative aspects of its responses is in progress, and the results will be published elsewhere.

## Sodium Extrusion in Muscle

THE extrusion of sodium from the living cell against a concentration gradient has been demonstrated by Steinbach[1], Desmedt[2] and Maizels[3]. The mechanism of such an extrusion is often referred to as a 'sodium pump'. We have repeated the above experiment with nerve and muscle; but we find it difficult to obtain consistent results, because toad (*Bufo marinus*) tissue does not always lose potassium and gain sodium in the cold. This pump is not entirely activated by temperature change, as the above authors neglect to stress that extrusion of sodium does not take place unless the external potassium is increased above physiological level.

In the course of work on ionic equilibria[4,5], we had occasion to investigate the level to which the intracellular sodium would fall when the tissues were placed in Ringer solution of which half the sodium had been replaced by sucrose. A pair of muscles (or nerves) is allowed to equilibrate in normal Ringer solution for 2 hr. (longer for nerves), and then one member is analysed and the companion transferred to Ringer solution in which half the sodium has been replaced by sucrose. It is found that the intracellular sodium decreases to half that of the control. It will be apparent from a study of Fig. 1 that this sodium has been extruded against a chemical gradient. We have found that this 'pump' is extremely reliable when contrasted with the vagaries of the Steinbach pump.

A survey of the time relationships shows that the sodium extrusion may be complete (in small muscles) in as short a period as half an hour, usually within an hour, and no further ionic alteration takes place during the following three hours.

The 'pump' described differs in one particular respect from that of Steinbach in that the potassium-levels remain constant throughout the whole of the experiment, whereas according to Steinbach there is a concomitant pumping in of potassium when the

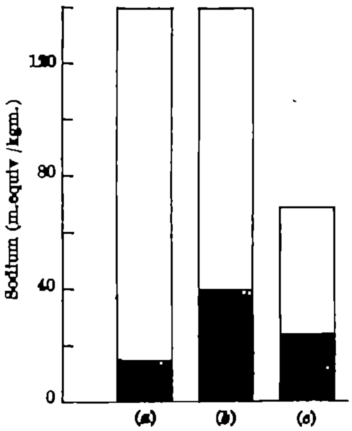

Fig. 1. (*a*) Muscle unsoaked (shaded) and in normal plasma (unshaded); (*b*) muscle soaked (shaded) and in normal Ringer (unshaded); (*c*) muscle soaked (shaded) and in half-sodium Ringer (unshaded).

Sodium content of muscle is calculated on an intracellular basis and on wet-weight. (The loss of sodium from muscle soaked in normal Ringer, when placed in half-sodium Ringer, is a loss against a concentration gradient)

cold muscles are warmed. Thus our experiment provides another example of the non-reciprocity of sodium and potassium movements (for other examples, see ref. 4).

The independence of the movements of sodium and potassium is further emphasized when we consider the action of metabolic inhibitors on the extrusion of sodium into the half-sodium Ringer solution.

The nature of the 'pump' has been investigated in the following manner:

*Cold*: the extrusion of sodium is entirely inhibited by reducing the temperature to 5° C.; but the potassium-level is unaffected.

*Monoiodo acetic acid* (1 m$M$): prevented extrusion of sodium and caused considerable loss of potassium. The tissues were bunched and failed to contract on stimulation.

*Sodium fluoride*: toad muscle appears to be resistant to the action of this inhibitor, but at high concentration (30 m$M$) the extrusion of sodium is inhibited without affecting the potassium-level.

*Calcium lack*: as the level of calcium will be reduced by sodium fluoride, the effect of calcium-free Ringer solution was tested. Extrusion of sodium was not inhibited and potassium remained constant.

2 : 4-*Dinitrophenol*: the extrusion of sodium is not inhibited by 2 : 4-dinitrophenol at a concentration of $10^{-3}$ $M$, although the muscles showed marked loss of potassium, and failed to contract on stimulation.

*Azide*: this inhibitor was also without effect on the extrusion, but at a concentration of 3 m$M$ caused marked loss of potassium and bunching of the tissue.

*Yohimbine*: did not affect the extrusion of sodium or alter the potassium level; but at $5 \times 10^{-4}$ $M$ the muscles failed to respond to stimulation.

*Cyanide* (5 m$M$): did not affect the extrusion of sodium, or alter the potassium-level. The muscles contracted well on stimulation.

It would appear probable from this limited range of inhibitors that the energy for the extrusion of sodium is derived from the glycolytic part of the respiratory cycle.

There was no extra oxygen uptake by the muscle during the extrusion of sodium.

The resting and action potentials were follow by means of internal micro-electrodes. During whole of the period there was little or no alterati in the resting potential (88 mV.). Within a f minutes of placing the muscle in the half-sodi solution the action potential fell from 132 mV. 115 mV. There was no subsequent rise in acti potential, although sodium was being extruded fr the cell until the original gradient was restored, wh is in contradistinction to the results of Desmedt[2].

## Adenosine Triphosphate in the Adrenal Medulla of the Cow

During investigations on the specific adre medullary granules containing adrenaline and n adrenaline[1], it was found that these structures ha high contents of acid-labile phosphorus. In prel inary experiments with ion-exchange chromatogra on 'Dowex 2' using formic and hydrochloric acid eluting agents, a fraction was obtained in which t main part of the acid-labile phosphorus was recover Judging from the ultra-violet absorption and t ratio pentose : acid-labile phosphorus : total ph phorus, the chief compound in this fraction seem to be adenosine triphosphate. Therefore the meth of Cohn and Carter[2] for separation of adenos phosphates was applied to adrenal medullary extrac

The medulla of cow suprarenal glands, remov from the body 40–60 min. after killing the anima was extracted with 10 per cent trichloroacetic ac in the cold. The barium and alcohol-insoluble ph phorus compounds were precipitated together by t method of LePage[3], dissolved in 0·1 $N$ hydrochlo acid and the barium removed with sulphu acid. The solution was brought to about $p$H 8 with ammonium hydroxide and the phosphorus co pounds were adsorbed on a 'Dowex 2' colu (200–400 mesh, chloride form, 40 mm. × 13 mm flow-rate 0·5 ml./min.). They were eluted (flow-ra 1 ml./min.) according to the method of Cohn a Carter[2] (two experiments) or according to the mo fication of this method by Deutsch and Nilsson[4] (fi experiments). Fractions of 25 ml. were collecte analysed for inorganic phosphorus, acid-labile ph phates, total phosphorus and pentose, and the ult violet absorption was measured. Phosphorus w determined by the method of Martin and Dot Acid-labile phosphorus was estimated after hydroly (8 min.) in 1 $N$ hydrochloric acid at 100° C. Pent estimations were carried out according to the meth of Albaum and Umbreit[6]. Optical densities we measured in a Beckman spectrophotometer, Mo *DU*, the molecular extinction coefficient of adenos triphosphate at 257 mμ (14,200) being used.

Only 7–14 per cent of the acid-labile phosphor ($P_2$ in Fig. 1) appeared in the fractions eluted wi 0·01 $M$ hydrochloric acid – 0·02 $M$ sodium chlori and with 0·01 $M$ hydrochloric acid – 0·05 $M$ sodi chloride. The remaining part (86–93 per cent of t

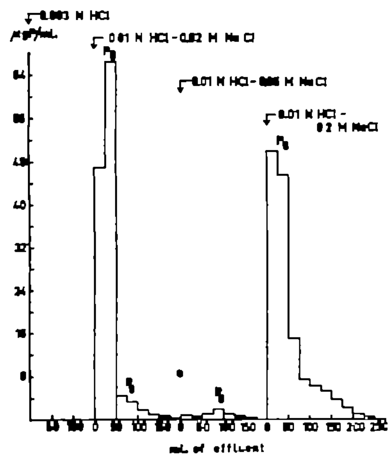

Fig. 1

al acid-labile phosphorus of the barium and ohol-insoluble phosphorus compounds) was eluted th 0·01 $M$ hydrochloric acid – 0·2 $M$ sodium loride (Fig. 1). The ultra-violet absorption and e molar ratios pentose : acid-labile phosphorus : tal phosphorus of these latter fractions indicated at the eluted compound was adenosine triphosphate. e identity and purity of the preparations were ecked after isolating them as the barium salt from oled fractions and converting the salt to the free id with 'Dowex 50' (hydrogen form) by paper romatography and by counter-current distribution alyses.

$R_F$ values, identical with those of adenosine phosphate isolated from rabbit muscle, were tained by two-dimensional paper chromatography cording to Deutsch and Nilsson[7].

Craig counter-current distributions were carried t with 11 ml. of each phase per tube in system 6 ed by Plaut, Kuby and Lardy[8] for separation of osphoric esters by solvent partition.

It would appear from Fig. 2 that the experimental rves, calculated from pentose and ultra-violet sorption, agree well with the theoretical ones. Moreover, the calculated partition coefficient is in se agreement with that obtained for adenosine phosphate isolated from rabbit muscle. The partin coefficients obtained under our experimental nditions (10·1) have been compared with those ported by Plaut, Kuby and Lardy[8] (15), and the ference seems not to lie beyond the limits of error.

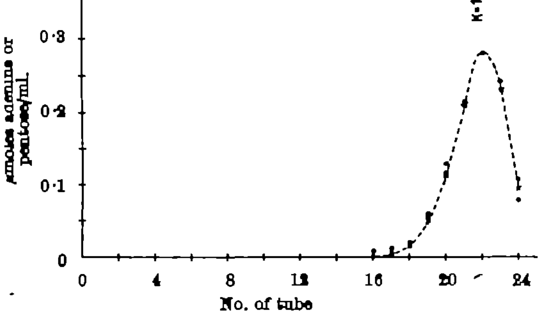

Fig. 2. Counter-current distribution of adenosine triphosphate rom cow adrenal medulla in the system hexanol, octadecylamine/ ater (pH 7·05); ●, pentose; ○, ultra-violet absorption optical density at 257 mμ; × – – ×, theoretical curve for $K = 10·1$

In the seven experiments, the following amounts of adenosine triphosphate were found, calculated on the basis of the phosphorus contents : 520, 445, 585, 500, 420, 595 and 400 mgm. (free acid) per 100 gm. wet weight of cow medulla. Preliminary experiments show that practically all the adenosine triphosphate is localized to the particular granules containing adrenaline and noradrenaline in the cytoplasm of the medullary cell, and that no appreciable breakdown occurs during several days in granules isolated and suspended in 0·3 $M$ sucrose and kept at 4° C.

The large amounts of adenosine triphosphate and its stability in the cow suprarenal medulla suggest that this tissue may be a suitable source for large-scale preparation of this substance.

The investigation has been supported by a grant from Statens Medicinska Forskningsråd.

## Filterability of the Swarmers of *Rhizobium* and *Azotobacter*

ALTHOUGH the existence of tiny, motile swarmers as a stage in the life-cycles of the nitrogen-fixing bacteria, *Rhizobium* and *Azotobacter*, has been known for many years, recent authoritative reviews[1] have cast doubt upon the genuineness of the phenomenon.

The ability of the swarmers of *Rhizobium* to pass through a Chamberland candle has been recorded[2]; but those of *Azotobacter* are not known to have been filtered successfully[3].

In the course of some observations upon the life-cycles of these bacteria, the swarmers of both genera have been separated from the vegetative cells by filtration, and from the filtrate new cultures have successfully been made. This offers conclusive proof of the validity of the complex life-cycle in both cases.

It appears that much of the previous work in this field has been carried out without consideration of the size of the filter-pores or that of the gonidia to be filtered. Microscopic examination showed that the size of the gonidia was about a quarter of the width of the vegetative cell, that is, 0·3 micron in the case of *Rhizobium* gonidia and 0·8 micron with *Azotobacter*. 'Sinterware' sintered glass filters were employed. These were cleaned with concentrated nitric acid each time they were used ; then, after washing well with water, the filter, filter flask and a container for the filtrate inside the filter flask were autoclaved before use.

Cultures were grown on potato agar and the growth emulsified with Ringer's solution. A coarse filter (No. 2) was first employed in order to remove the large aggregates of particles. A manometer and an air-leak were fitted to the pump so that the pressure could be controlled at – 500 mm.

With *Rhizobium* cultures a No. 5 filter was used. This has a pore size of one micron and will pass particles up to 0·8 micron. Results were rather variable; sometimes it was possible to filter the gonidial stage, at other times it was not, although microscopic examination showed that gonidia were being produced. These variations may possibly be due to the close size of the swarmers and the filter pores.

In the case of *Azotobacter*, consistent results were obtained with a No. 4 filter, which will pass particles less than 3 microns in diameter. Young cultures were used as controls. These were examined microscopically to ascertain that they were not producing gonidia. It was found that filtrates from these cultures contained no viable cells, whereas filtrates from the gonidia-producing cells gave a heavy growth on subculture. By centrifuging the filtrates and examining microscopically, it could be shown that no vegetative cells had passed through the filter.

Failure in the past to filter *Azotobacter* gonidia would appear to be due to workers using filters that were too fine; de Regel[3], for example, used filters with a pore size of 0·75 micron. This would certainly not allow the passage of *Azotobacter* gonidia.

## Erosion in Meanders

Secondary flows are developed when a non-uniform stream passes through a bend, the plane of which contains the vorticity vector of the entry flow[1]. The importance of such secondary velocities in the erosion of river meanders was pointed out originally by Thompson[2], and large transverse secondary velocities have been observed in the flow of air through pipe bends, at Cambridge and elsewhere[3].

Experiments have been conducted in Cambridge on a water flume to investigate the rate of erosion in meanders of different amplitude. The cross-section of the channel at the beginning of each of these experiments was an equilateral triangle of side 4 in., and the water velocity was 6–8 in. per sec. during the experiments. A standard mixture of sand and aluminous cement was used to form the meanders.

Fig. 1 shows the shape of the meanders in the first experiment, and the nature of the erosion observed.

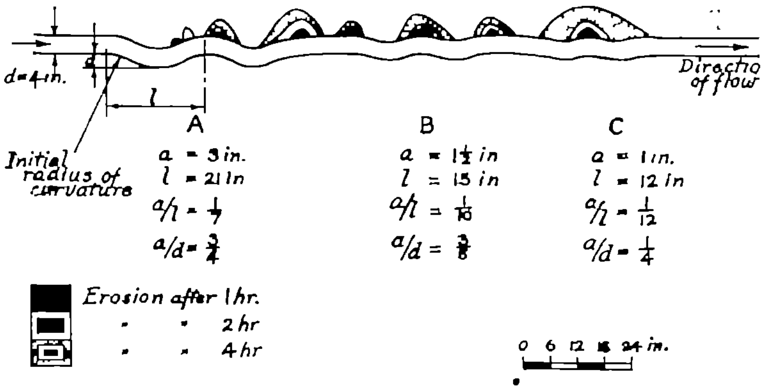

Fig. 1

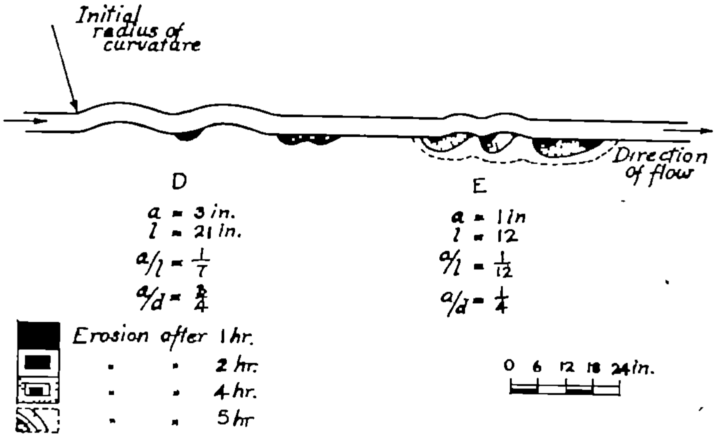

Fig. 2

The rate of erosion was greatest for the smalle meander (*C*) and least in the largest meander (*A* The walls of the channel were eroded on the outsi of the meander bends; but almost all the erosic was confined to one wall of the channel, namely, t wall on the outside of the initial bend curvatur The high-velocity water near the surface would l displaced towards this wall by secondary motion i the initial bend[3].

In a second experiment, the initial curvature each meander was reversed, and the direction any secondary rotation therefore also reverse Fig. 2 shows the development of the meanders an indicates that erosion was now completely confine to the other side of the channel; that is, once aga the side towards which the high-velocity part of th stream should be diverted by secondary motion i the initial bend. A longer settling length between large and a small meander was used in this secon experiment; but the small meander (*E*) was erode more rapidly once more, the erosion starting in eac meander on the outside of those bends of the san radius of curvature as the initial radius of curvatur

These investigations were made in co-operatic with the Ouse Catchment Board.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

### Monday, November 28

RITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture atre of the Science Museum South Kensington, London, S.W.7), .30 p.m.—Mr. Frank Greenaway: "Models of Molecules—Some orical Observations".

OCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at the mical Society, Burlington House, Piccadilly, London, W.1), at p.m.—Mr. K. Wilson-Jones: "The Control of Parasitic Weeds".

### Tuesday, November 29

NIVERSITY OF LONDON (at Bedford College, Regent's Park, London, .1), at 4.30 p.m.—Dr. W. J. L. Sladen: "Biological Research he Antarctic" (Stevenson Lecture).*

NSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT SECTION nt meeting with the RADIO SECTION, at Savoy Place, London, 2), at 5.30 p.m.—Dr. C. J. N. Candy: "The Specification of the perties of the Thermistor as a Circuit Element in Very-Low- quency Systems" and "A Vector Method for Amplitude-Modulated nals".

OYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the Sir n Cass College, Jewry Street, London, E.C.3), at 6.30 p.m.—Dr. J. P. Martin, F.R.S.: "Gas–Liquid Chromatograph".

NSTITUTION OF MECHANICAL ENGINEERS, EDUCATION GROUP (at irdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—ussion on "Laboratory Work—Purpose and Methods".

OYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, .), at 7 p.m.—Mr. F. B. Greatrex: "The Noise of Jet Engines".

OCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, Portland e, London, W.1), at 7 p.m.—Mr. A. St. Johnston: "Electronic nputing Methods".

OCIETY FOR ANALYTICAL CHEMISTRY (in the Beveridge Hall, versity of London, Senate House, London, W.C.1), at 7.30 p.m.—f. J. Heyrovský (Prague): "The Development of Polarographic lysis".

### Wednesday, November 30

RITISH NUCLEAR ENERGY CONFERENCE (joint meeting of the TITUTION OF CIVIL ENGINEERS, the INSTITUTION OF MECHANICAL INEERS, the INSTITUTION OF ELECTRICAL ENGINEERS, the INSTI- E OF PHYSICS and the INSTITUTION OF CHEMICAL ENGINEERS, he Institution of Civil Engineers, Great George Street, London, .1), at 2.15 p.m.—Inaugural Meeting. Sir Christopher Hinton, .S.: Opening Address; Sir John Cockcroft, F.R.S.: "The ted Kingdom Atomic Energy Project"; Mr. V. A. Pask and Mr. . Duckworth: "The Place of Nuclear Energy in United Kingdom er Development"; Mr. H. J. Grout: "The Use of Research ctors in Nuclear Power Development"; Mr. A. S. Maclean and Dr. H. Marley: "Health and Safety in a Nuclear Power Industry".

OYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at p.m.—Anniversary Meeting.

OYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, .2), at 2.30 p.m.—Mr. L. C. Nickolls: "Scientific Aspects of the ection of Crime".

RITISH INSTITUTION OF RADIO ENGINEERS (at the London School Hygiene and Tropical Medicine, Keppel Street, Gower Street, don, W.C.1), at 6.30 p.m.—Mr. H. J. Leak: "High Fidelity dspeakers—the Performance of Moving-Coil and Electrostatic nsducers".

OYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting the SOUTH-WEST ESSEX TECHNICAL COLLEGE CHEMICAL SOCIETY, he South-West Technical College, Forest Road, Walthamstow, don, E.17), at 7 p.m.—Dr R. N. Haszeldine: "Fluorocarbons their Future".

OCIETY FOR ANALYTICAL CHEMISTRY (at the Chemical Society, ington House, Piccadilly, London, W.1), at 7 p.m.—Mr. A. A. les: "Atomic Energy and the Analyst".

### Thursday, December 1

NSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, .2), at 5.30 p.m.—Lieut.-Cdr. F. R. J. Spearman, Mr. J. J. Galt, A. V. Hemingway and Mr. R. W. Hynes: "TRIDAC—a Large logue Computing Machine".

OYAL AERONAUTICAL SOCIETY (in the Main Dining Hall, Airmen's , A. and A.E.E., Boscombe Down), at 6.30 p.m.—Mr. P. A. ton: "Free Flight Techniques for High Speed Aerodynamic earch".

HEMICAL SOCIETY (at the Royal Institution, Albemarle Street, don, W.1), at 7.30 p.m.—Dr. E. W. R. Steacie, F.R.S.: "Re- ns of Radicals in Gaseous Systems" (Liversidge Lecture).

### Friday, December 2

NIVERSITY OF LONDON (at Charing Cross Hospital Medical School, ndos Place, London, W.C.2), at 5 p.m.—Dr. R. K. Burns (Carnegie itution of Washington): "Experimental Studies of Sex Differ- tion in the Opossum".*

OYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at n.—Mr. E. J. H. Corner: "Botanical Collecting with Monkeys".

### Saturday, December 3

BRITISH INTERPLANETARY SOCIETY (in the York Hall, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Mr E. Burgess: "Probing Interplanetary Space".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT (Grade B) IN PHYSICS—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (November 30).

ASSISTANT LECTURER (with a good honours degree or Associateship of the Royal Institute of Chemistry, and research and/or industrial experience) IN CHEMISTRY, at the Technical College of Monmouthshire, Crumlin—The Director of Education, County Hall, Newport, Mon. (November 30).

BIOCHEMIST, Scientific Officer grade, for research work on the organic chemistry of the hop plant—The Registrar, Wye College, near Ashford, Kent (November 30).

COMPUTER (with an ordinary pass degree in mathematics or equivalent qualification) IN THE DEPARTMENT OF PHYSICS, for work in connexion with a programme of research on the crystal structure of organic compounds—Joint Clerk to the University Court, Queen's College, Dundee (November 30).

RESEARCH FELLOW (with research experience, preferably on natural products) IN CHEMISTRY, at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1 (November 30).

AREA CHIEF SCIENTIST (preferably with a good honours degree, with considerable experience of industrial science, fuel technology and laboratory administration)—The Staff Director, National Coal Board, East Midlands Division, Sherwood Lodge, Arnold, Notts, quoting S.V.467 (December 3).

LECTURER or ASSISTANT, Grade B (with special interests in inorganic chemistry, high academic qualifications with good teaching and/or research experience), IN THE DEPARTMENT OF CHEMISTRY—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (December 3)

LIBRARIAN (with a scientific background, preferably with a pass degree or equivalent, and proficient in German) for a small but specialized library—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (December 8).

ASSISTANT LECTURER or LECTURER IN PHYSICS—The Registrar, The University, Sheffield (December 10).

RESEARCH ASSISTANT (with a first-class or good second-class honours degree in chemistry) IN THE COAL CONSTITUTION LABORATORY of the Department of Mining, to be a member of a team carrying out research on the chemical constitution of coal, including the examination of the products of mild oxidative degradation of coal—The Professor of Mining, The University, Edgbaston, Birmingham 15 (December 12).

SENIOR LECTURER and LECTURERS (2) IN THE DEPARTMENT OF BOTANY, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 12).

LECTURER IN PHYSIOLOGY, at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1 (December 15).

PROFESSOR OF MARINE ENGINEERING; PROFESSOR OF HYDRAULIC MACHINES; PROFESSOR OF TEXTILE ENGINEERING; and a PROFESSOR IN PRODUCTION OF ARMAMENTS AND AMMUNITIONS—The Dean, Faculty of Engineering, Alexandria University, Alexandria, Egypt (December 17).

RESEARCH STUDENT (with a good honours degree in chemistry) IN CHEMISTRY—The Registrar, University College of North Staffordshire, Keele, Staffs (December 17).

LECTURER/SENIOR LECTURER (preferably with experience in endocrine or reproductive physiology) IN VETERINARY PHYSIOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 19).

LECTURER (with special qualifications in hydraulics) IN THE DEPARTMENT OF FLUID MECHANICS—The Registrar, The University, Liverpool (December 19).

LECTURER (with special interest in the fields of low temperature and solid state physics) IN THEORETICAL PHYSICS, in St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (December 31).

RESEARCH ASSISTANT IN AERONAUTICS—The Secretary of University Court, The University, Glasgow (December 31).

SENIOR LECTURER IN CIVIL ENGINEERING, at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (December 31).

IMPERIAL CHEMICAL INDUSTRIES FELLOWS (3) for research in chemistry, physics and allied subjects, including the biological application of chemistry—The Registrar, University Office, 46 North Bailey, Durham (January 9).

STAFF TUTOR (with qualifications in and, if possible, experience of extra-mural teaching in zoology and/or botany with particular reference to the promotion of field studies among adult students) IN NATURAL HISTORY in the Department of Extra-Mural Studies—The Secretary, Queen's University, Belfast (January 16).

ASSISTANT LECTURER (Grade A) IN THE DEPARTMENT OF CHEMISTRY AND BIOLOGY, College of Technology and Commerce, Cardiff—The Director of Education, City Hall, Cardiff.

ASSISTANT LECTURER (with an honours degree in chemistry and able to teach one branch of chemistry up to B.Sc. special chemistry degree standard, and preferably with industrial experience) IN THE SCHOOL OF CHEMISTRY—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

BIOCHEMIST (with a first- or second-class honours degree in biochemistry or equivalent qualification, and with postgraduate research experience) to assist in the study of certain physico-chemical properties of mucin, initially for a period of two years—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 55/20.

BRADFORD DYERS' ASSOCIATION LIMITED RESEARCH FELLOW (with high qualifications in science) to undertake research in tinctorial chemistry, textile chemistry or an allied subject—The Principal, Technical College, Bradford.

CHEMIST or BIOCHEMIST (with an honours degree) in the Serum Department, for the routine control of therapeutic sera and research on biochemical and biophysical problems in the field of serum proteins—The Secretary, The Lister Institute, Elstree, Herts.

ENGINEERS and PHYSICISTS, Senior Scientific and Scientific Officer grade (with an appropriate first- or second-class honours degree or equivalent high professional attainments) in Royal Naval Scientific Service Experimental Establishments, chiefly in the Weymouth and Portsmouth areas and Home Counties—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.344/5A.

HOSPITAL PHYSICIST (Senior grade), to serve the Radiotherapy Departments of the General Hospital, Southend-on-Sea, and the Essex County Hospital, Colchester, in association with the Physics Department of the London Hospital—The Secretary, Southend-on-Sea Hospital Management Committee, General Hospital, Southend-on-Sea.

MATHEMATICAL CONSULTANT (with a mathematical or science degree, and preferably with experience of electrical computing machines) IN THE ENGINEERING RESEARCH DEPARTMENT for work consisting of computation and mathematical analysis of problems relating to all branches of audio and radio frequency and television engineering—Engineering Establishment Officer, Broadcasting House, London, W.1, quoting E 315.N.

PHYSICISTS, Scientific Officer class and Experimental Officer class, at Ministry of Supply Research and Development Establishments, chiefly near Farnborough, Hants; Malvern, Worcs; Salisbury, Wilts; and Sevenoaks, Kent; for work on guided weapons, rockets, gas turbines, aerodynamics, aircraft structures and equipment, armaments, instrumentation including optics, and electronics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.396/5A.

PRINCIPAL SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree or equivalent, and at least three years postgraduate research experience, and a good basic knowledge of radio engineering and experience in the development of telecommunications apparatus) at the Ministry of Supply Headquarters, London, for work associated with the development of field and fixed radio equipment, television, counter measures, telemetry, vehicle installations, and radio navigation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.520/5A.

PSYCHOLOGIST in the Research Department—The Secretary, Royal Eastern Counties Hospital, Abbeygate House, Colchester, Essex.

RESEARCH ASSISTANTS for research on the chemical physics of polynuclear aromatic compounds, and on the melting mechanisms of ionic crystals—Prof. A. R. Ubbelohde, Imperial College, London, S.W.7.

RESEARCH FELLOW (with a degree in electrical engineering or in physics) IN THE ENGINEERING LABORATORY, University of Oxford, to work under the direction of the Donald Pollock Reader, Dr. H. Motz, on problems of millimeter wave generation—Prof. A. Thom, Engineering Laboratory, 19 Parks Road, Oxford.

RESEARCH WORKER (with a veterinary qualification or a good honours degree in a biological subject, and preferably with experience in microbiology and/or histology), to study problems associated with virus infections of animals; and a RESEARCH WORKER (with an honours degree in a biological subject and an interest in ecology) for original research on parasitic worms of livestock—The Secretary, Animal Diseases Research Association, Gilmerton, Edinburgh 9.

SENIOR SCIENTIFIC OFFICERS (with a first- or second-class honours degree or equivalent in physics or engineering, and preferably with a knowledge of aircraft or aircraft systems) at a Ministry of Supply Experimental Establishment, near Amesbury, Wilts, for planning and development of special trials of aircraft guided weapon systems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.410/5A.

SENIOR TECHNICIAN IN ZOOLOGY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

TECHNICAL EDITOR (with a degree in engineering, metallurgy or science, experience of technical editing, and familiarity with welding terms)—The Secretary, Institute of Welding, 2 Buckingham Palace Gardens, London, S.W.1.

THEORETICAL PHYSICIST (with a first- or second-class honours degree in physics, and at least three years postgraduate research experience, preferably in the field of motion and coagulation of particulate suspensions) to work on problems of size distribution in coagulating and dispersing particulate suspension—The Senior Recruitment Officer, United Kingdom Atomic Energy Authority, Aldermaston, Berks, quoting 726/2.

# SUPPORT FOR SCIENCE TEACHING IN SCHOOLS

ALTHOUGH the Appleton Committee, in reporting on the supply of teachers of mathematics d science in Scotland, rejected the suggestion that or conditions in many school laboratories is a eason for the lack of recruits to science teaching, it d not deny that some school buildings are old and attractive and that some laboratories are sparingly uipped. Moreover, if the standard of school science ildings and equipment is, in general, as satisfactory England and Wales as the Appleton Committee und it to be in Scotland, the indications are that e standard is likely to deteriorate rapidly in the sence of special assistance. The maintained condary schools are able to look to public funds to able them to extend their laboratories and to prove their equipment and facilities for science aching ; and Sir David Eccles has said enough in cent months to justify them in facing the impending ulge' with some confidence that their resources will increased sufficiently to enable them to cater ficiently for the anticipated and desired increase scholars studying science.

The independent schools in Britain have no such nfidence, and any expansion must be financed out their own resources. They are reluctant to raise eir fees further, although these have not risen ough to cover the whole cost of running and panding the schools. If indeed fees have not yet ached the limit, that limit must shortly be set by e same factor of increasing taxation in the higher vels which is already drying up the private benections and endowments which in the past brought e schools into being, and have made possible the tstanding education for which they are famous.

These schools, with their fine tradition of scholarip in the humanities, represent a valuable potential urce of scientists and technologists. But first it ll be necessary to overcome the reluctance apparent them to enter on such careers ; a reluctance to hich the Advisory Council on Scientific Policy and eakers in both Houses of Parliament in recent detes on scientific and technical man-power, the shorte of science teachers and similar themes have rected attention, as well as Sir Alexander Todd in s address to the Parliamentary and Scientific Comittee last July on the scientific man-power probm. For that reason alone it is fitting that industry ould come forward and assume some of the sponsibility which private individuals are ineasingly unable to discharge. The Industrial Fund r the Advancement of Scientific Education in hools, which as announced in *Nature* of November p. 860, has been established by seventeen chemical, ectrical and mechanical engineering companies, is tended to provide funds for the considerable pansion in the provision of buildings and equipent which is required if the independent schools d direct grant schools in the United Kingdom, the Channel Islands and the Isle of Man are to make their fitting contribution to the increased supply of scientists and technologists that the nation needs.

This initiative was warmly welcomed by the Minister of Education, Sir David Eccles, in the course of a reply to a question in the House of Commons on November 1 regarding the improvement of facilities for advanced science teaching in the schools. In that reply Sir David said that since 1945, about a thousand new laboratories had been built or started in maintained grammar or technical schools. In a written reply on November 10 he estimated the cost of these as £1·5 million in technical schools, just under £3 million in grammar schools and £9 million in modern secondary schools. He expressed the hope that authorities will continue to use their freedom in minor works to improve science accommodation ; but he said he is ready to consider on their merits projects which could not be executed for less than £10,000.

Whatever reservations may be held as to the effect of the establishment of the Industrial Fund for the Advancement of Scientific Education in Schools on the supply of science teachers, it cannot be other than beneficial and will enable the schools to offer opportunities in science to an increasing number of boys and girls. This is desirable not only from the point of view of public or industrial administration, but also from that of the production of scientists or technologists, as Sir Henry Tizard emphasized in his Haldane Memorial Lecture last March. Moreover, it should be noted that the examples of research carried out in schools cited by Dr. A. G. Lowndes in his paper at the Birmingham meeting of the British Association were carried out in independent schools. The improved facilities which this new Fund may make possible in such schools should assist the recruitment of first-class science teachers, and Mr. J. T. Stock has recently directed attention to this aspect. In a recent note in *The Times Educational Supplement*, he described the results which have followed the granting to him and a colleague at Norwood Technical College, in consequence of the Ministry of Education Circular 94 of 1946 on Research in Technical Colleges, of five hours a week relaxation of teaching duties for research in chemistry. Some 90 per cent of this work, largely on the design and development of micro- and semi-micro-apparatus and techniques, has been carried out with equipment and materials normally available in schools.

This particular work has received a fair amount of recognition, notably in exhibits at the Science Museum and at the International Congress on Analytical Chemistry at Oxford in 1952 and in a B.B.C. Science Review telefilm ; but its importance in the present connexion is its demonstration of the potentialities of research with a modest official allowance of time. The factor is certainly one not to be discounted lightly ; and it is even possible that, as regards the recruitment of science teachers and the supply of scientists and technologists, the great value of the establishment of the new Fund will lie in the increased prestige which is thereby given to science and to technology as careers. Indeed, if its full effect is to be felt, it is important that scientists should make every effort to overcome whatever obstacles continue to hinder the ablest boys and girls in the independent or the grant-aided schools from taking up a science career. Equally, of course, it is important that other firms should follow the lead of the institutors of the Fund.

In this connexion it is worth recalling the provocative remark made by Sir Henry Tizard thirty-five years ago, and which he quoted in his Haldane Memorial Lecture, that the fame of the old School of Greats at Oxford was not really due to the intrinsic merits of the two subjects studied, but rather to the fact that men who took high honours in it had been specially selected at school to read classics because of their outstanding ability. Sir Henry went on to argue that any other two subjects would serve equally well for the training of the minds of men who are going into the Civil Service and other professions, provided that they are equally difficult and well taught, and to suggest that in this scientific age one of the subjects of Modern Greats should be science, and the other modern philosophy, history or economics. The suggestion was even then taken quite seriously; but its relevance to the teaching of science in the independent schools is in stressing the importance of quality. If, as there seems to be some reason for believing, in spite of the increase in the number of university students since the War, there has been no proportionate increase in the number of those obtaining first-class honours, it is of the utmost national importance that a reasonable proportion of the ablest students entering the universities each year should study science.

To ensure this, there must be no undue bias against science in the schools; and every effort must be made to see that the opportunities of science and technology as careers are fairly presented, and that the claims of science and technology as intellectual disciplines are fully understood by headmasters and their staffs. On them must rest a large responsibility for guiding the ablest young minds under their care to consider the claims of a career in science or technology; but it is no less important that such careers should have the prestige and status in the public mind which can be as important as remuneration in attracting recruits of high quality. The decisive factor is often the influence of the science master himself. If the new Fund, by furthering the provision of laboratories and equipment and improving teaching conditions generally, increases the prestige of science and those who teach it in the schools, then it may well help to attract teachers of ability and enthusiasm. In this way it may make a decisive contribution, not so much to the early removal of the shortage of science teachers, as to ensuring that a fitting proportion of the ablest minds in the sixth forms of schools each year turn to science or technology as a career.

# ISOTOPES IN THE SERVICE OF GEOLOGY

**Isotope Geology**

By Prof. Kalervo Rankama. Pp. xvi+535. (Londo
Pergamon Press, Ltd.; New York: McGraw-H
Book-Company, Inc., 1954.) 75s. net.

IN 1950 Prof. K. Rankama proposed the ter
'isotope geology' to cover the investigation
geological problems by means of research on t
occurrence and natural history of isotopes, a
especially the variations of their relative abundance
Some of the vast possibilities of this fascinating a
rapidly expanding field of discovery are bei
actively explored by several enthusiastic teams
workers, and already the output of literature h
become an accelerating stream with which only
specialist can hope to keep pace. Geologists hav
therefore good reason to be grateful to Prof. Rankan
for giving them this admirable account of the pri
ciples of the subject and for making so readily avai
able the results achieved up to very nearly the da
of publication. The book is divided into two part
of which the first is a remarkably lucid account
the physical and chemical principles involved in t
various methods and techniques, while the second
devoted to summarizing and discussing all t
relevant information about the isotopes of most
the elements, with special reference to actu
examples of isotope fractionation in Nature and t
geochemical processes responsible. Part 2 is muc
more than a compilation of data and a guide to t
literature—although in these respects alone it
invaluable—for on every appropriate occasion t
author discusses the geological significance of t
results and directs attention to the many critical ga
where more data are urgently required. Indeed, fe
books can have been written in which so man
opportunities for productive research are freely pr
sented. For example, we can now clearly see how
solve some of the more tantalizing problems of petr
genesis and ore deposits, while at the same tim
realizing that each successful forward step will requi
organized and patient team-work, and the expenditu
of much time and money. The stimulating effect
of this book should help to shorten the time very su
stantially by adding to the numbers of eager worker

Among the problems to which useful contribution
have already been made, the measurement of ge
logical time stands out as by far the most famili
and successful. During recent years the radiocarbo
method has made it practicable to begin the co
struction of a world-wide 'atomic calendar', goin
back perhaps some thirty thousand years, whic
would provide an 'absolute' chronology if the fund
mental assumption of long-term constancy of cosmi
ray intensity could be justified. Dating of sampl
already dated by varves is the obvious requirement
but as yet this has not been systematically carrie
out. Indeed, if E. Antevs (*J. Geol.*, 63, 499; 1955)
correct in concluding that the radiocarbon age f
the celebrated Two Creeks forest bed (11,400 year
is at least 8,000 years too young, the method wi
eventually disprove the assumption and show ho
the intensity of cosmic rays can be 'calibrated' ov
the period that has been measured by varves.
the other end of the known time-scale, the metho
based on the accumulation of radiogenic isotopes
lead have been successfully applied to the dating
meteorites, by the use of techniques that would ha

med little short of miraculous a few years ago. the many topics involved in geochronology—and w outside, such as the 'age' of the elements them-res—are treated competently and critically, with rm and frank assessment of the difficulties that re still to be overcome. For example, in discussing ether or not the rates of decay of the radioactive lides have varied with time, Rankama pertinently nts out that the argument for constancy based on asurements of pleochroic haloes is not infallible, ce a considerable variation in the decay constant uld be necessary to produce a detectable change the range of the alpha-particle concerned.

n the field of petrogenesis the author very erously gives me credit for having made the first structive suggestions involving 'isotope geology', ed on the inference that the isotope of calcium erated by the radioactive isotope of potassium uld increase during geological time about twenty-en times as fast in granites as in basaltic rocks. that time (1932) it seemed to be quite practicable determine the abundance-ratios that were needed decide whether various rocks had been formed by ferentiation or not, and if not, whether some such cess as replacement or transfusion had operated. is optimism was based on the mistaken belief, n current, that the radioactive isotope of potas-m was of mass 41 and that its decay product was cium-41. It was not until 1935 that Nier showed active nuclide to be potassium-40. In the erim, as Rankama records on p. 315, "the method s actively investigated by the magneto-optic thod developed by F. Allison in the United States, no results were published". It was very fortunate us that we were cautious enough to abstain from blishing, and it may be of interest to place on ord how we eventually came to realize that, what-r was being measured, it was not calcium-41. er a period of two years I sent scores of analysed k-powders to Dr. Allison for the determination of lcium-41'. The results were dramatically exciting l, despite a few disturbing discrepancies, I felt e that we had found a powerful new key for ocking at least some of the secrets of petrogenesis. the hope of tracing the source of the discrepancies ent a dozen samples of marine limestones, fossils l shells of known age, ranging from the present to back in the Pre-Cambrian, expecting to find that ratio of 'calcium-41' to total calcium had increased tematically during geological time. Alas, there s no increase ! The Pre-Cambrian ratios did not fer appreciably from the values for modern shells l sea water. This pulled us up with a painful jerk ; l the discovery about the same time that no such tope as calcium-41 is detectable by the mass ctrograph (the decay product in question being cium-40) raised what were then, and still are, uperable difficulties against making a fresh start h the right isotopes. Increase of the ratio of ontium-87 to strontium-86 with geological time uld be much more easily detectable in marine mical sediments, as Wickman pointed out in 1948 ; Rankama has still to report that even this highly mising method has so far failed to yield satis-tory results.

More positive progress in tracing the origins of ks, minerals, natural waters and gases has been ieved by determining the variations in the isotopic stitutions of such elements as carbon and oxygen. e chapters on these elements are consequently ong the longest and most informative. Baertschi's investigations are notable for their demonstration that both oxygen-18 and carbon-13 vary considerably in metamorphic limestones, ranging from the relatively low values characteristic of sedimentary types to the higher values given by carbonatites of igneous origin. The high values occur at contacts where, presumably, great quantities of juvenile carbon dioxide, water, etc., traversed the rocks and effected isotope exchanges during their passage. Various investigators have found that oxygen-18 tends to be more abundant in granitic than in basaltic rocks, which is not what would be expected if these rocks were related by differentiation. The heavy isotope of silicon also tends to concentrate slightly in the more silicic rocks. However, much more evidence of this kind is required for a variety of elements, in critically selected suites of rocks having known relationships, before firm conclusions can be reached, and here the co-operation of field geologists is essential. Rankama's chapter on magnesium—twenty lines, only—reflects a paucity of data for a very common element that is lamentable in view of the many problems connected with stony meteorites, ultrabasic rocks and basalts that still await solution.

Important applications that are already under way include the assessment of the palæo-temperatures corresponding to the growth conditions of carbonate shells of Jurassic and later ages (the 'carbonate thermometer') and of the distributions of climate so implied. Similarly, the isotopic constitution of sulphur in pyrite depends on the temperature at which the mineral crystallized ; for example, in hydrothermal deposits the crystals become relatively enriched in sulphur-32 as the temperature decreases. A study of marine sulphates and sulphides of various ages has suggested to Thode and others that organic fractionation of sulphur did not occur on an appreciable scale until towards the close of the Pre-Cambrian. Here there is a hint that the earlier atmosphere may have been deficient in free oxygen and that the later rapid development of oxidizing conditions may have favoured the extraordinary efflorescence of Cambrian life-forms. While sounding a cautious note of warning, Rankama comments on the fascination of these problems and the urgent need for much more detailed research.

The book has a bibliography of more than thirteen hundred items, an index of authors and an unusually detailed and efficient subject index. The only criticism as to style is that the author has picked up the bad habit of using the word 'data' as if it were a singular noun. It may not be out of place to direct the attention of publishers' readers to this all-too-common fault. Few misprints have been detected ; one that should perhaps be mentioned occurs in equation 75.27 on p. 383, where $^{235}$U should be $^{238}$U. There is a related mistake in the reference to me on p. 386, concerning which I need only say that I was not guilty of having paid no attention to the isotopic constitution of uranium in my calculations.

Prof. Rankama is to be congratulated on a very impressive achievement, and the publishers on the production of a handsome volume that is worthy of its contents. The book will be found invaluable by scientific workers in a wide variety of subjects besides geology and geochemistry, and many of its readers will doubtless join with the reviewer in the hope that supplements embodying the results of current and future researches in the same fields may be prepared at intervals by this distinguished author to whom we owe so much already. ARTHUR HOLMES

# PHYSICAL MEASUREMENT IN GAS DYNAMICS AND COMBUSTION

### Physical Measurements in Gas Dynamics and Combustion

Edited by R. W. Ladenburg, B. Lewis, R. N. Pease and H. S. Taylor. (High Speed Aerodynamics and Jet Propulsion—Vol. 9.) Pp. xvi + 578. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1955.) 84*s*. net.

THE great advances in aeronautical science have been accompanied by remarkably fast developments in experimental techniques for studying the various aspects of the flow of gases. The first part of this volume, which is the ninth of a series of twelve on high-speed aerodynamics and jet propulsion, deals with methods of measurement of density, pressure, temperature, velocity and state of turbulence. Developments in the usual methods, such as schlieren photography, interferometry, hot-wire anemometry, piezoelectric pressure gauges, temperature measurements from infra-red radiation, and shielded thermocouples, are described. A number of interesting, and sometimes surprising, recent or possible techniques are also examined: these include the use of active nitrogen for following density changes at very low pressure; the use of ultra-violet or X-ray absorption spectra to measure density; determination of velocity from the quenching of glow discharges; study of polarization and wave-length distribution of scattered light for mist condensation problems; the use of light reflected at grazing incidence to determine the thickness of a shock wave; and the determination of the surface temperature of projectiles in flight by coating them with a temperature-sensitive phosphor.

The second part of the book deals with measurements on combustion gases; this is restricted to physical methods, as another volume, on "Combustion Processes", is in preparation. There are chapters dealing with flame photography, temperature measurements, determination of burning velocity, flame spectroscopy, the use of mass spectra, and analysis of the structure of the flame front. Standard methods are again covered, and some new techniques are discussed; these include developments in the spectrum-line reversal method of temperature measurement to give the temperature of complex flames, and the use of line broadening and Doppler shift to give pressure and gas velocity in rocket-motor flames; spectroscopic determination of effective rotational temperature; and the study of the thick reaction zone of flames at very low pressure.

The sections in the part of the book on gas dynamics tend to be rather short and specialized, so that the effect is like a series of articles in a review journal, such as *Reviews of Modern Physics*, rather than a unified book. The combustion section, although limited to physical measurements, consists of longer, more comprehensive articles. Dr. E. F. Fiock's on burning velocities is very clear and includes new results; Dr. F. P. Bundy and Dr. H. M. Strong's is particularly good on the spectroscopic temperature measurements; Dr. W. T. Reid's on flame photography is easy to read but incomplete; Prof. G. H. Dieke gives a good account of developments in photoelectric spectroscopy as applied to flames; and Mr. N. Thomas stresses the value of the new techniques for the detailed understanding of flame structure.

The rapid developments in the many aspects
this field of research made the book necessary. T
inevitable time-lag in publication is probably
sponsible for some omissions; there does not app
to be any mention of quantitative neutral-we
schlieren photography, or of studies of flame struct
from measurements of refractive index made with
inclined slit.

The book comprises twenty-four articles
twenty-two authors. Generally the standard is hi
and these articles, at an advanced level, in which
many developments in techniques are discussed,
welcome. Most of the articles are naturally rat
specialized, so that most people working in some p
of this extensive field will find a few articles
considerable value but also others which cann
easily be read. There is a single collected subje
index for the whole book, but no author-index. T
full references at the end of each article are, of cour
valuable.

A. G. GAYDO

---

# MALARIA IN RETROSPECT

### Man's Mastery of Malaria

By Dr. Paul F. Russell. (University of Lond
Heath Clark Lectures 1953.) Pp. xv + 308 + 24 plat
(London: Oxford University Press, 1955.) 25*s*. n

THE sixteen years which have elapsed since t
start of the Second World War have seen gr
developments in the control and treatment of malar
In Ceylon the case-rate per 1,000 living has fal
from 574 in 1940 to 11 in 1953. In Greece the to
deaths from malaria in 1942 were 1,856; in 19
there were only 14 deaths from this disease. In Ita
Sicily and Sardinia malaria has been practica
eradicated. An illuminating commentary on impro
ments in treatment is given by the fact that, wher
in Italy, Sicily and Sardinia approximately 300,
cases resulted in 8,407 deaths in 1919, in 19
approximately 400,000 cases resulted in only
deaths. Since 1948 there have been no malar
deaths in the Italian Republic. Results of this nat
are conducive to a sanguine attitude, and an exp
assessment of the position is therefore to be welcom
Dr. Paul F. Russell devoted his Heath Clark Lectu
to this subject in 1953, and in their published fo
they provide an excellent résumé of the history
the disease and an authoritative discussion of t
results of recent measures.

Malaria has a venerable history. Empedocles
supposed to have delivered the city of Selinus fr
pestilence by diverting two neighbouring streams
that they cleansed the mouth of the river. In Rom
times malaria was associated with marshes, and
the Campagna and elsewhere Roman engine
carried out much drainage. Hippocrates gave exc
lent descriptions of the clinical features of malar
and also commented on the effect of marshes a
stagnant waters in producing enlarged splee
Despite the warnings given by Celsus, Varro, Colu
ella, Galen and other classical authors, the Pont
Marshes were not successfully drained until t
ten-year task which ended in 1940, and success
drainage in Greece is even more recent.

In the case of the malaria parasite there was a
an unconscionable lapse of time between the fi
glimmerings of recognition and the period wh
practical use could be made of the discovery. T
characteristic pigment was seen in spleen and br

otions by Lancisi in 1716 and by Bright in 1831. hey did not associate the pigment with malaria. oth Virchow and Frerichs described the pigmented lls and associated them with malaria. Frerichs and elafield (1872) probably described the parasite—e plasmodium—without recognizing it. In 1880 lphonse Laveran recognized the fact that these dies were living parasites, and as a result of his illiant studies and the work of the Italian investitors, Marchiafava, Celli, Golgi and their colborators, part of the life-history of the vivax and artan parasites was known within the next few ars. Yet in 1886 Osler was definitely sceptical—til he had found the crescent forms for himself. uring all this period there was much speculation on e means whereby the parasite was transferred from infected to an uninfected individual. Mosquitoes d been suspected from ancient times, but Beaurthuy (1854) was probably the first medical writer state that they were vectors. In 1882 King, of ashington, D.C., listed nineteen reasons why osquitoes must be considered responsible, and he as so convinced of his rightness that he recomended that the whole city of Washington should be vested in a closely woven metal screen as high the Washington Monument. Manson's brilliant osquito–malaria hypothesis (1894) is well known; ut it is perhaps not so frequently realized that he issed the fact that the parasite, sucked from man y the mosquito, was later injected directly into nother individual. He thought that the spores of e malaria parasite were liberated by the mosquito to water, which was later drunk by the individual ho became infected. Ross devoted three years of tensive research to the discovery of the malaria orozoites in the salivary gland of a mosquito, and though he worked out fully the life-cycle of the alaria parasite of birds (proteosoma), by ill-luck he as denied the final proof of the man-to-mosquito-man cycle, which was made by Italian workers in 898.

For nearly fifty years after these crucial disoveries there was doubt regarding what actually appened after an infected mosquito bit an uninfected dividual. In 1903 Schaudinn described how the orozoites penetrated the human red-blood coruscles; but no one else had ever seen this phenmenon. It was not until just before the Second orld War that it was discovered in birds that the orozoites developed into pre-erythrocytic forms in e liver, spleen and bone-marrow, and that these rms then developed into unpigmented exoerythrotic forms before they invaded the blood corpuscles. he demonstration of these phenomena in the human bject demanded a healthy individual who was illing to be infected experimentally and then to ave a small portion of his liver removed for histogical examination. In 1948 and 1949 this important emonstration was made for *Plasmodium vivax* and . *falciparum* by Shortt and his colleagues. The cubation period was thus explained, and a better tarting-point was provided for the testing of new herapeutic remedies.

Much has been written on the history of cinchona om its introduction to Europe in 1632. Pelletier nd Caventou discovered quinine and cinchonine, wo of its four basic alkaloids, in 1820, and the other wo, quinidine and cinchonidine, were discovered ithin the next twenty-five years. Although obviously ecifics for malarial attacks, all these substances ave certain disadvantages. Some of these have been obviated by the newer synthetic drugs, such as pamaquine, mepacrine, chloroquine, proguanil and daraprim. Despite the great strides which have been made, the ideal drug for both prophylaxis and treatment has probably still to be synthesized.

In this sphere of prophylaxis, enormous progress has been made by destruction of mosquito larvæ and by preventing bites of adult insects. In the destruction of larvæ, oil was first used by Dunlap in 1793, and paris green was introduced in 1916. The work of Gorgas during the cutting of the Panama Canal was a magnificent example of what could be done by persevering work of this nature. In the campaign against the adult mosquito, DDT was a discovery of the highest practical value.

In these valuable lectures Dr. Russell has presented a very detailed summary of the history of malaria in language which can be understood by anyone who knows the barest elements of protozoology. He avoids the clinical features of the disease and concentrates on the parasite, the mosquito, and the results of prophylaxis and treatment. The word 'summary' is used advisedly. The literature of the subject is enormous, and Dr. Russell's very extensive bibliography is merely a token of what is available. It need scarcely be said that it is very carefully selected. Though Dr. Russell is perhaps not quite at home with the older material, he is a complete master of the modern literature. It is surprising that the Oxford University Press has allowed a number of un-English terms to slip through—such as 'editorialized' and 'sanitating'; after all, the lectures were delivered in one English university and printed at the press of another. It is disconcerting also to find in the text that the title of an article in a journal is italicized as though it were a book—though the conventional practice is always used in the bibliography. Otherwise, the production of the book comes up to the high standard of previous Heath Clark Lectures.

In his preface Dr. Russell specifically explains that the title of his book does not necessarily mean that malaria has been eradicated. There are, indeed, some small clouds on the distant horizon. Although malaria parasites were exposed to cinchona and its alkaloids for three hundred years without showing signs of drug resistance, some strains have now begun to show this property. Further, in some areas these strains have been spreading—for example, *Plasmodium falciparum* in Malaya and *P. vivax* and *P. malariae* in Indonesia. At present this resistance can be overcome by the administration of full doses of proguanil from the outset; but the parasite apparently has the next move. Again, certain species of mosquitoes have become resistant to DDT, so that in Greece and Java this method of prophylaxis is no longer possible. There are many sociologists and demographers who hold that the great advances made in the control of malaria will lead to epidemics of that disease, or alternatively to over-population and famine. In the final part of his book Dr. Russell skates gracefully over this slippery ice without attempting to make much headway. Perhaps he does not intend to, since the legitimate goal of the medical man is yet far distant. Dr. Russell estimates that at the present time 250 million persons suffer attacks of malaria yearly and 2·5 million die of it. In this field there is still sufficient work in hand for the Rockefeller Foundation, of the staff of which Dr. Russell is a distinguished member.

E. Ashworth Underwood

# PROTEIN SYNTHESIS IN ISOLATED CELL NUCLEI

By DR. V. G. ALLFREY and DR. A. E. MIRSKY
The Rockefeller Institute, New York
AND
SYOZO OSAWA*
Biological Institute, Nagoya University

IN experiments described previously, it was noted that nuclei prepared from the thymocytes of the calf can actively incorporate DL-alanine-1-$^{14}C$ into their proteins when incubated *in vitro*. This activity of the isolated nucleus required that its deoxyribonucleic acid remain intact: the incorporation of amino-acid was seriously impaired by pretreatment of the nucleus with deoxyribonuclease. A partial recovery of deoxyribonuclease-treated nuclei could be observed when a supplement of calf thymus deoxyribonucleic acid was added to the incubation mixture[1].

The present communication is concerned with the further investigation of protein synthesis by the isolated nucleus, with the role of deoxyribonucleic acid (DNA) in this process, and with the capacity of the thymocyte nucleus to meet its energy requirements through the synthesis of high-energy phosphate bonds.

A rapid procedure for the preparation of nuclei from the thymus of the calf has already been described[1,2]. In its essentials, the method involves a controlled homogenization of the tissue in cold 0·25 *M* sucrose solution containing a small amount of calcium chloride. Coarse fibre is removed by filtration through gauze and through flannelette, and the nuclei are separated by fractional centrifugation and thoroughly washed. In the experiments about to be described the nuclei were prepared in 0·25 *M* sucrose containing 0·0020 *M* calcium chloride.

Nuclei so isolated meet a surprising number of the requirements which we consider desirable and necessary before a study of their biochemical attributes is undertaken. First, in overall composition and in enzymic constitution these 'sucrose' nuclei are the equivalent of nuclei prepared from the thymus under non-aqueous isolation conditions, that is, by a modified Behrens' procedure[3,4]. The latter nuclei are selected as a standard of comparison because their purity has been established by chemical, enzymatic and immunological tests, and because only non-aqueous conditions of isolation preclude an exchange of water-soluble materials between nucleus and cytoplasm. A detailed comparison of thymus nuclei isolated in sucrose with those prepared by the Behrens' procedure has shown that nuclei isolated in sucrose have retained their water-soluble enzymes[3]. The deoxyribonucleic acid content is the same (2·5 per cent DNA-P) for nuclei prepared by the two procedures, which indicates that their overall protein content is also the same.

Other evidence concerning the integrity and cleanliness of the 'sucrose' nuclei comes from careful examination of such preparations under the microscope. We have made use of ordinary light, phase-contrast, interference and electron microscopy. The electron microscope is of particular value for discerning and estimating the extent of contamination by intact, small thymocytes. The proportion of su intact cells in nuclear preparations is relatively lo For example, two preparations examined in this w have shown 45 and 77 small thymocytes per thousa nuclei, respectively. Thus the electron microgra support the demonstration by other optical a chemical methods that there is no gross contamination of the nuclei with whole cells or cytoplasm debris[5]. However, it should be noted that caref microscopic examination often reveals small bits strands of cytoplasm adhering to some of the nucl The extent of this contamination cannot be estimat quantitatively under the microscope, but nucleic ac analyses and enzyme measurements make it cle that the level of cytoplasmic contamination lies w below 10 per cent.

When a suspension of nuclei in buffered sucro medium is shaken at 37° C., in the presence DL-alanine-1-$^{14}C$ or glycine-1-$^{14}C$, there is a rap incorporation of the isotope into nuclear protein It should be mentioned that what is actually measur in most of the experiments described is the avera specific activity of the proteins which are precipitat in 5 per cent trichloroacetic acid (TCA). Nucle acids are extracted and removed with hot trichlor acetic acid and lipides are removed by successi treatments with hot alcohol, alcohol–chloroform ether mixtures, ether, and acetone. The remaini protein is homogenized in acetone, collected filter-paper planchets, and the carbon-14 activit measured using a Geiger–Müller tube and scali circuit[1]. More than 94 per cent of the carbon-1 activity of the isolated protein remains after trea ment with 0·25 *N* sodium hydroxide for two hour and more than 89 per cent remains after reactio with ninhydrin.

The time course of a typical incorporation exper ment is given in Fig. 1. It can be seen that after a initial lag period of 10–15 min., $^{14}C$-amino-aci incorporation proceeds linearly up to 90 min. an then begins to taper off. The phenomenon is aerobi The incorporation of $^{14}C$-alanine or $^{14}C$-glycine in a atmosphere of nitrogen is negligible (Table 1). Th uptake is also greatly inhibited by $10^{-3}$ *M* sodiu cyanide and by $10^{-4}$ *M* dinitrophenol. Methylen blue ($2·5 \times 10^{-4}$ *M*) has no effect on amino-aci incorporation. The addition of a supplementa energy source leads to a slight increase in nucle activity. For example, glucose or α-ketoglutara added to the incubation medium raises the level isotope incorporation by 10–20 per cent.

One of the most striking effects on nuclear amin acid incorporation is that produced by sodium ion Nuclei isolated by the procedure described require sodium ion supplement to the medium in order t synthesize protein actively. The effect of varied sodiu concentration on the level of amino-acid uptake shown in Fig. 2. There is a well-defined maximum about 0·068*M*. The specificity of the sodium requir

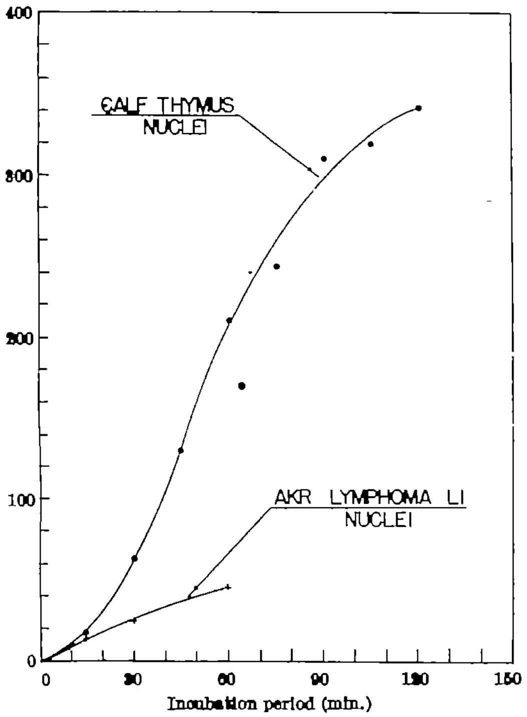

Fig. 1. The time course of incorporation of alanine-1-$^{14}C$ into the proteins of isolated nuclei. The incubation flasks contained 1 ml. of nuclear suspension (100 mgm. (wet weight) of nuclei per ml. of 0·25 *M* sucrose – 0·0020 *M* $CaCl_2$), 0·5 ml. of 0·1 *M* sodium phosphate – 0·25 *M* sucrose buffer at *p*H 7·3, 0·4 ml. of 0·1 *M* glucose containing 6·25 mgm. of NaCl per ml. and 0·1 ml. of DL-alanine-1-$^{14}C$ solution containing 0·5 mgm. = 0·008 mc. per ml. The flasks were shaken in a 37° bath for the indicated periods and the uptake then halted by the addition of an equal volume of 10 per cent trichloracetic acid. The protein was prepared and its carbon-14 activity determined as previously described (ref. 1)

ment is emphasized by a series of experiments summar-ed in Fig. 3. In these tests an attempt was made to ubstitute all or part of the sodium in the incubation medium with an equal amount of potassium. In all ases the total salt concentration was kept constant. t is evident that when all the sodium is replaced by potassium the synthetic activity falls to 15 per cent of the optimal value; increasing the $Na^+/K^+$ ratio results in a corresponding increase in the amount of amino-acid incorporated. The extreme dependence of the synthetic activity of the nucleus upon the sodium ion concentration has made it necessary to control rigorously the sodium-level of the incubation medium. In all the experiments described below supplements of sodium chloride were added to bring the final sodium ion concentration to 0·068 *M*. The relationship between the sodium- and potassium-level in the medium and that within the nucleus is at present being investigated.

able 1. Effect of Anoxia, Cyanide, Dinitrophenol and Added Metabolites upon $^{14}C$-labelled Amino-acid Incorporation by Isolated Calf Thymus Nuclei

| Conditions of experiment | Isotope administered as | Specific activity of nuclear protein (c.p.m./mgm.) |
|---|---|---|
| *A.* Nuclei in $O_2$<br>Nuclei in $N_2$ | glycine-1-$^{14}C$<br>,, | 71<br>14·7 |
| *B.* Nuclei in $O_2$<br>Nuclei in $N_2$ | DL-alanine-1-$^{14}C$<br>,, | 72<br>10·4 |
| *C.* Nuclei without added dinitrophenol<br>Nuclei in 2 × $10^{-4}$ *M* dinitrophenol | DL-alanine-1-$^{14}C$<br>,, | 72<br>11 |
| *D.* Nuclei without added dinitrophenol<br>Nuclei in 1 × $10^{-4}$ *M* dinitrophenol | DL-alanine-1-$^{14}C$<br>,, | 154<br>58 |
| *E.* Nuclei without added cyanide<br>Nuclei in 0·001 *M* sodium cyanide | DL-alanine-1-$^{14}C$<br>,, | 64<br>13 |
| *F.* Nuclei without added metabolite<br>Nuclei + 40 *μM* glucose<br>Nuclei + 40 *μM* α-ketoglutarate | glycine-1-$^{14}C$<br>,,<br>,, | 86<br>99<br>109 |

The synthetic activity of the isolated nucleus can be readily destroyed either by heating, or by freezing and thawing. Nuclei stored at 2° C. gradually lose their ability to incorporate $^{14}C$-amino-acids. The rate of decline in activity with storage varies considerably in different preparations; but in most cases activity is well retained for 4–6 hr. and almost entirely lost after 24 hr. at 2°. Nuclei prepared in hypertonic sucrose solutions (for example, 1 *M*) are inactive. Nuclei prepared in 0·25 *M* sucrose and afterwards placed in 1 *M* sucrose solution also lose their activity.

## Nature of the Incorporation Process

There are several experiments now to be described which make it clear that the uptake of labelled amino-acids into nuclear proteins represents protein synthesis and is not simply a random or non-specific exchange reaction.

The first of these experiments is the demonstration that only the L-enantiomorph of the administered DL-alanine-1-$^{14}C$ is incorporated into nuclear protein. The ability of the nucleus to distinguish between

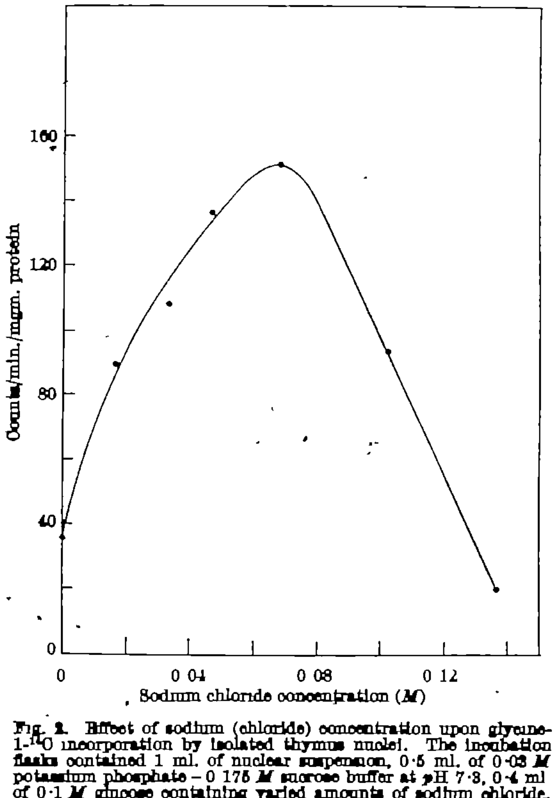

Fig. 2. Effect of sodium (chloride) concentration upon glycine-1-$^{14}C$ incorporation by isolated thymus nuclei. The incubation flasks contained 1 ml. of nuclear suspension, 0·5 ml. of 0·03 *M* potassium phosphate – 0·175 *M* sucrose buffer at *p*H 7·3, 0·4 ml of 0·1 *M* glucose containing varied amounts of sodium chloride, and 0·1 ml. of glycine-1-$^{14}C$ solution containing 1·0 mgm. = 0·018 mc. per ml. The incubation period was 60 min.

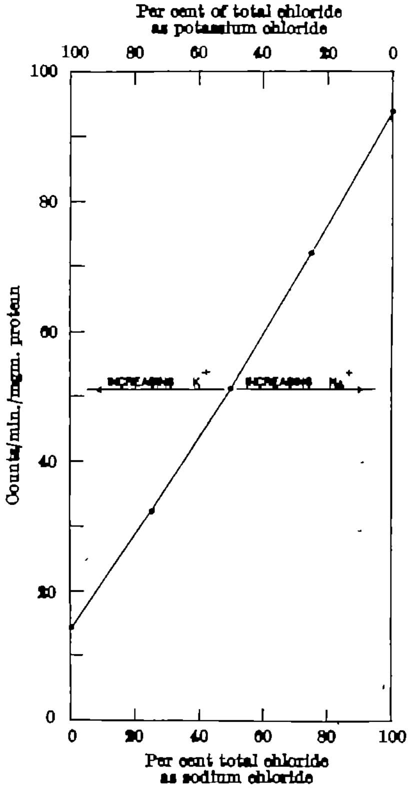

Fig. 3. Effect of varying sodium : potassium ratio upon glycine-1-$^{14}$C incorporation by isolated thymus nuclei. The incubation flasks contained 1 ml. of nuclear suspension, 0 5 ml of 0 03 *M* potassium phosphate – 0·175 *M* sucrose buffer at *p*H 7·3, 0·4 ml. of 0 1 *M* glucose containing 0 187 m*M* of total chlorides, the ratio of sodium to potassium being varied as indicated in the chart, and 0·1 ml. of glycine-1-$^{14}$C solution containing 1·0 mgm. = 0·018 mc. per ml. The incubation period was 60 min.

D and L forms of the amino-acid is readily indicated by the experiments summarized in Fig. 4. In these tests increasing amounts of unlabelled D-alanine or unlabelled L-alanine were added to the incubation medium together with the DL-alanine-1-$^{14}$C. If both the D and the L forms of the $^{14}$C-alanine were utilized by the nucleus then both unlabelled isomers should compete with isotopic molecules for acceptance by the nucleus, and the carbon-14 activity of the nuclear protein should be correspondingly lowered. Actually, the addition of unlabelled D-alanine has no such effect; only the L-isomer competes for incorporation. It follows, therefore, that only the L-form of the $^{14}$C-alanine administered is utilized for protein synthesis by the nucleus.

A second experiment was designed to test whether the incorporated amino-acid is in constant exchange with other amino-acid molecules in the medium. If the uptake of amino-acids is indeed reversible then $^{14}$C-alanine once incorporated into nuclear proteins should be exchanged with unlabelled L-alanine added to the medium after incorporation has occurred. This was tested in the experiments summarized in Fig. 5. Incorporation of $^{14}$C-alanine was allowed to proceed for 45 min. At that time a large excess of unlabelled L-alanine was added to the incubation medium. In 'control' experiments an equal amount of unlabelled D-alanine was added. Samples of the nuclei were removed at 15-min. intervals and the carbon-14 activity of the nuclear protein measured in the usual way. It is evident from the curves that adding an eightfold excess of unlabelled D-alanine has no effi on the normal time course of carbon-14 incorporatio The addition of unlabelled L-alanine acts to suppr further incorporation of alanine-$^{14}$C, as could ha been predicted from the previous experiment; b the specific activity of the nuclear protein contin to rise. It follows that $^{14}$C-alanine once incorporat into protein is not constantly being replaced unlabelled alanine in the medium. Similar expe ments have been performed using a 200-fold exc of unlabelled L-alanine. No exchange was noted to 180 min. after addition of the unlabelled amin acid, although 'control' experiments showed that t nuclei were still actively incorporating $^{14}$C-alani over the entire period. Thus the incorporation labelled amino-acids represents a synthetic rath than an exchange reaction.

## Role of Deoxyribonucleic Acid in Protein Synthesis

The notion originally suggested by Brachet[6] a Caspersson[7] that ribonucleic acids play a part in pr tein synthesis is now widely accepted as demonstrate The most direct evidence in its favour comes fro the work of Gale and Folkes on protein synthes in bacterial cell residues[8], and from studies amino-acid incorporation by a ribonucleoprote complex of the liver[9]. In both cases ribonuclea acts to suppress amino-acid incorporation.

The isolated cell nucleus affords a unique oppo tunity to test the role of the deoxyribonucleic acids the process of protein synthesis, and the results ha a special interest because they ultimately bear the mode of action of the gene, and on the chemic relationships between the nucleus and the cytoplas

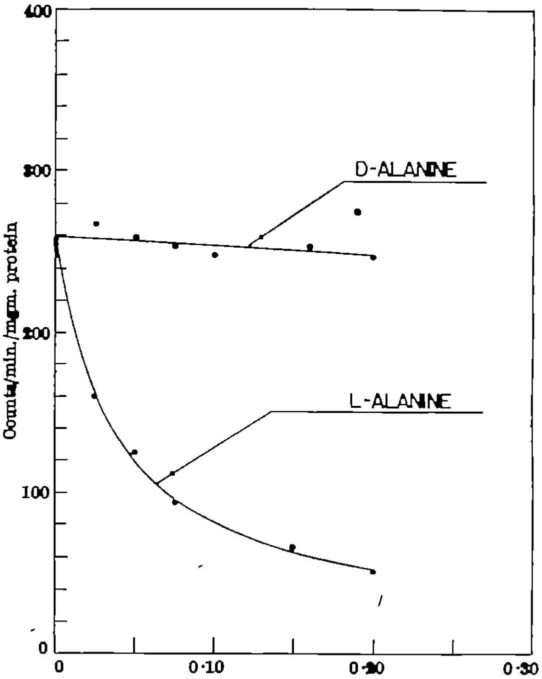

Fig. 4. The effect of unlabelled D- and L-alanines upon incorporation of DL-alanine-1-$^{14}$C by isolated thymus nuclei. The incubation vessels contained 1 ml. of nuclear suspension, 0·6 ml. of 0·1 *M* sodium phosphate – 0·25 *M* sucrose buffer (*p*H 7·3) containing varied amounts of either D- or L-alanine, as indicated in the chart, 0·4 ml. of 0·1 *M* glucose containing 6·25 mgm. NaCl per ml. and 0·1 ml. of DL-alanine-1-$^{14}$C solution containing 0·5 mgm. = 0·008 mc. per ml. The incubation period was 60 min.

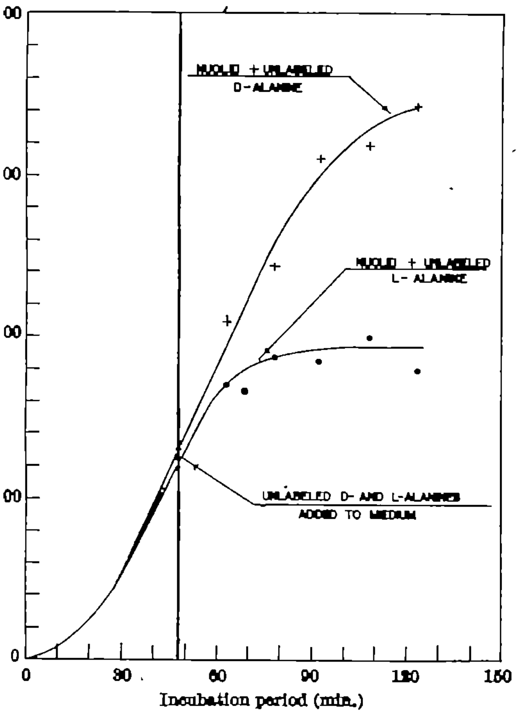

ig. 5. The retention of incorporated alanine-1-$^{14}C$ following ddition of a large excess of unlabelled D- or L-alanine after ptake has occurred. The incubation vessels contained 1 ml. of uclear suspension, 0·5 ml. of 0·1 *M* sodium phosphate – 0·25 *M* ucrose buffer at pH 7·3, 0·4 ml. of 0·1 *M* glucose containing ·25 mgm. NaCl per ml. and 0·1 ml. of DL-alanine-1-$^{14}C$ solution ontaining 0·5 mgm. = 0·008 mc. per ml. The latter solution upplies 0·025 mgm. of labelled L-alanine. Samples were ncubated for 45 min., at which time 0·2 mgm. of unlabelled - or L-alanine was added. Samples were then withdrawn at 5-min. intervals, and the activity of the nuclear proteins determined in the usual way

A number of experiments which relate deoxyribo- cleic acid to the process of protein synthesis in the cleus will now be described. Several of these periments deal with the effect of deoxyribonuclease the uptake of labelled amino-acids. When isolated lei are treated with crystalline pancreatic deoxy- onuclease before adding $^{14}C$-amino-acids, the incorporation of the latter is markedly impaired. The results in Table 2 show that the degree of impairment becomes more serious as more and more of the deoxyribonucleic acid is degraded. Removal of practically all the deoxyribonucleic acid leaves only 15 per cent of the activity observed in appropriate 'controls'. These findings suggest a direct role of deoxyribonucleic acid in nuclear protein synthesis.

Additional support for this conclusion arises from experiments which test whether the synthetic activity of nuclei treated with deoxyribonuclease can be restored by the addition of supplementary calf thymus deoxyribonucleic acid. In these experiments the nuclei were treated with deoxyribonuclease under the conditions summarized in Table 3. The activity of the enzyme was then blocked by the addition of citrate, and a deoxyribonucleic acid supplement was added. The isotopic amino-acid was then supplied, and incorporation allowed to proceed for 60 min. The specific activity of the protein in nuclei which had received a deoxyribonucleic acid supplement was then compared with the protein activities in 'control' nuclei which had been treated with the enzyme in the same way but which had not received any additional deoxyribonucleic acid. The results of such experiments all agree in demonstrating that added calf thymus deoxyribonucleic acid does in fact restore a part of the original activity of the nucleus.

It is a matter of considerable interest to determine whether nucleic acids other than calf thymus deoxyribonucleic acid can restore the synthetic capacity of deoxyribonuclease-treated thymus nuclei. Several such experiments are now in progress, and it has been very tentatively concluded that the thymus nucleus can distinguish between thymus deoxyribonucleic acid and that prepared from wheat germ.

Since deoxyribonucleic acid is required for nuclear protein synthesis, the question naturally arises as to how the deoxyribonucleic acid participates in amino-acid incorporation. Several experiments were performed to test whether the action of deoxyribonucleic acid requires the active participation of its free phosphate groups. The results of these experiments are summarized in Table 4. The procedure used was to add varying amounts of basic compounds which are known to combine with the free phosphoric acid

Table 2. EFFECT OF DEOXYRIBONUCLEASE AND RIBONUCLEASE ON $^{14}C$-AMINO-ACID INCORPORATION BY THYMUS NUCLEI

| Conditions of experiment* | Isotope administered as | Nucleic acid removed (per cent) | Specific activity of protein (c.p.m./mgm.) | Decrease in $^{14}C$ incorporation (per cent) |
|---|---|---|---|---|
| 1. Nuclei preincubated with 0·13 mgm. DNase for 15 min. before adding isotopic amino-acid<br>'Control' nuclei (preincubated without DNase) | glycine-1-$^{14}C$<br>" | 47<br>— | 144<br>205 | 30<br>— |

| ,, ,, ,, ,, ,, ,, ,, | 10 | 4·8 | 108 |

* In these experiments the incubation flasks contained 1·0 ml. of nuclear suspension, 0·5 ml. of 0·1 *M* sodium phosphate – 0·25 *M* suc buffer (pH 7·3) and 0·4 ml. of 0·1 *M* glucose containing 8·16 mgm. NaCl and 4·19 mgm. $MgCl_2.4H_2O$ per ml. 0·1 ml. of DNase solut containing the indicated amount of enzyme was then added and incubation allowed to proceed for the indicated time. Then 1 ml. of D solution containing the indicated amounts of calf thymus DNA and 20 *μM* of sodium citrate was added, followed by 0·1 ml. (= 0·05 mg of DL-alanine-1-$^{14}$C solution. Incubation was continued for 60 min. 'Control' experiments were performed in the same way without adding DN

groups of deoxyribonucleic acid. The compounds selected included the basic dye, methyl green, and two basic proteins, protamine, and a lysine-rich histone prepared from calf thymus[10]. It is clear that the addition of small amounts of methyl green, protamine or histone to the nuclei before adding the isotopic amino-acid has little effect upon the uptake. Larger amounts lead to a partial impairment of carbon-14 incorporation; but the impairment may reflect osmotic or other damage to the system, since large amounts of added serum albumin also decrease the uptake.

A few other observations are included in Table The first deals with the effect of chloramphenic which has been shown to block protein synthesis bacterial systems[11]. This compound had little eff on amino-acid incorporation by isolated thym nuclei. A second observation is concerned with t effect of added cortisone, which has been shown cause involution of the thymus *in vivo*[12]. The additi of this steroid diminishes amino-acid uptake by t isolated nuclei.

Since deoxyribonucleic acid is required for prot synthesis in the nucleus, and ribonucleic acid is need

r protein synthesis in the cytoplasm, the question turally arises as to the role of ribonucleic acid within e nucleus. Attempts to relate the ribonucleic acid the thymus nucleus to nuclear protein synthesis ve not so far been successful. Treatment of the lated nuclei with ribonuclease before adding $^{14}$C-nino-acids has no effect on the uptake of the latter. owever, this result does not permit the conclusion at ribonucleic acid has no part in nuclear protein nthesis, because in the experiments mentioned only per cent of the nuclear ribonucleic acid was released the action of the enzyme.

One difficulty which should be mentioned in this nnexion is the problem of nuclear variability. uclei prepared from different thymus glands at fferent times of the year may vary considerably their properties. One way in which they vary is their susceptibility to ribonuclease. Several eparations (made during the winter months) re-ased all their ribonucleic acid when treated with e enzyme, whereas nuclei prepared more recently ere relatively resistant. The nuclear variability is ident in other properties as well: in osmotic operties, as evidenced by the tendency to form gels, d in the ability to retain the complement of acid-luble nucleotides.

*Which nuclear proteins become labelled?* The answer this question depends at the outset upon the istence of a dependable and meaningful scheme of actionating the proteins of the nucleus. This is a eld of endeavour which is now in its earliest stages development, though it promises to become a ajor topic of biochemical investigation.

We have developed a provisional fractionation ocedure which is applicable to the proteins of ymus 'sucrose' nuclei, and which permits the paration of several classes of proteins of different operties, and considerable biological interest. In s essentials the procedure is as follows. (See flow-eet in Fig. 6.) The nuclei are first extracted with H 7·1 potassium phosphate buffer. The extractable otein (Fraction 1) is about 10 per cent of the hole nuclear mass and contains about one-third of e ribonucleic acid of the nucleus. The nuclei are en suspended in 1 *M* sodium chloride, in which they swell and largely dissolve. The opalescent solution is centrifuged at 26,000 *g* to sediment the undissolved protein. This residue (Fraction II) also comprises about 10 per cent of the nuclear mass and contains one-third of the total ribonucleic acid. The supernatant after high-speed centrifugation contains the bulk of the protein of the nucleus and all the deoxyribonucleic acid. This solution is saturated with sodium chloride and brought to *p*H 10·9. The resulting precipitate is treated with acetate buffer at *p*H 4·1 to extract a histone fraction (Fraction III), leaving a gelatinous protein residue (Fraction IV). This gelatinous protein constitutes about 8 per cent of the nuclear mass. Its amino-acid composition and other properties show that it is not a histone. After removing the salt from the saturated sodium chloride supernatant, arginine-rich and lysine-rich histones[14] are removed in dilute acid. The residue contains all the deoxyribonucleic acid of the nucleus and a firmly attached protein fraction (Fraction V) the amino-acid composition of which shows that it is not a histone.

ACTIONATION OF THE PROTEINS OF ISOLATED CALF THYMUS NUCLEI

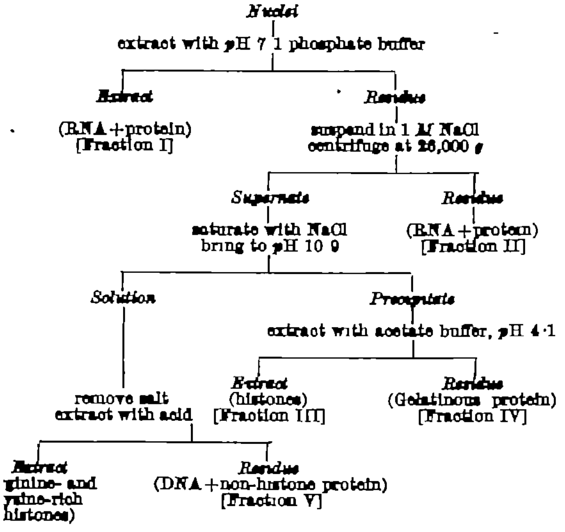

Fig. 6. Flow-sheet for the fractionation of the proteins of calf thymus 'sucrose' nuclei

Table 5. ALANINE-1-$^{14}$C INCORPORATION INTO DIFFERENT PROTEIN FRACTIONS OF THYMUS NUCLEI

| Protein fraction | Specific activity (c.p.m./mgm.) |
|---|---|
| Total nuclear protein | 107 |
| Fraction I (protein soluble in *p*H 7·1 buffer) | 179 |
| Fraction II (residue after extraction in *M* sodium chloride) | 117 |
| Fraction III (histones) | 36 |
| Fraction IV (gelatinous protein) | 157 |
| Fraction V (non-histone protein associated with DNA) | 243 |

When nuclei are incubated in the presence of $^{14}$C-alanine and afterwards fractionated according to the above scheme, wide variations in specific activity are observed in the different protein fractions. (It should be mentioned that the total alanine contents of the protein fractions are very similar, so that differences in carbon-14 concentration reflect differences in the metabolic activity of the various proteins.) The results of such an experiment are presented in Table 5. Several of the findings are of particular interest. First is the observation that the protein (Fraction V) which is most closely associated with the deoxyribonucleic acid is by far the most 'active' protein of the nucleus. This result lends further support to the conclusion drawn from deoxyribonuclease experiments that the deoxyribonucleic acid plays a direct part in protein synthesis. A second point of interest is the fact that the level of isotope incorporation into the histone protein (Fraction III) is relatively low. This result agrees with earlier *in vivo* experiments[15] in which it was noted that the incorporation of glycine-$^{15}$N into the histones of mouse liver, pancreas and kidney is much lower than the uptake into the residual proteins of the chromosome. Finally, it may be noted that the ribonucleoprotein complex which is extracted in *p*H 7·1 phosphate buffer has a high level of activity. It is tempting to speculate that this high activity in a protein fraction of the nucleus which is diffusible indicates a role of this protein in the mechanism by which the nucleus interacts with the cytoplasm.

Since a protein component of ribonucleoprotein can be synthesized in the isolated nucleus the question arises as to whether the isolated nucleus can also synthesize ribonucleic acid, and whether the ribonucleic acids in different fractions are synthesized at different rates. (It has already been reported that pig kidney nuclei isolated in sucrose can incorporate $^{32}$P-orthophosphate into their ribonucleic acid[14].) The ability of thymus and lymphoma nuclei to utilize glycine-$^{14}$C for ribonucleic acid synthesis, and the role of deoxyribonucleic acid in this process are currently being investigated. Preliminary experiments show that $^{14}$C-glycine is actively incorporated into the purines of the nucleic acids of isolated thymus nuclei.

## Energy-yielding Mechanisms in Isolated Nuclei

As considerable energy should be required for the active synthesis of protein in the nucleus, one would expect nuclei to contain an energy generating system, possibly involving energy-rich compounds such as adenosine triphosphate and related nucleotides. It has already been pointed out that the incorporation of $^{14}$C-amino-acids is an aerobic phenomenon, inhibited by both cyanide and dinitrophenol.

To determine the overall concentration and distribution of the nucleotides in thymus nuclei, analyses were first performed on the 'standard', that is, nuclei prepared in non-aqueous media by the Behrens' procedure. The cold acid extract of Behrens' type nuclei was fractionated by ion-exchange chromatography[15], and it was found that these nuclei contain mononucleotides of adenine, cytosine, uracil and guanine, together with several uridine diphosphate derivatives, the adenine nucleotides predominating in amount. The nucleotide analyses of the Behrens' type nuclei are in close agreement both quantitatively and qualitatively with similar analyses performed on whole tissue, indicating that in this respect at least no gross differences exist between nucleus and cytoplasm (Table 6).

When similar analyses are performed on thymus nuclei isolated in sucrose solutions it is found that they retain 60–80 per cent of their original acid-soluble nucleotide content. These nucleotides are well retained after repeated washings with cold sucrose – calcium chloride solution. From the analyses of the nucleotides found in thymus nuclei, a surprising observation came to light. During tl preparation of 'sucrose' nuclei in the cold, tl nucleotide monophosphates characteristic of tl excised tissue are largely converted back to tl energy-rich triphosphate forms which predomina in the living tissue. This synthesis of high-ener phosphate bonds is presumably the result of extensi aeration of the nuclear suspension during the isolati procedure.

Table 6. ADENINE NUCLEOTIDE CONTENTS OF ISOLATED CALF THYMUS NUCLEI

| Material analysed | Per cent of total $E_{260}$ present as AMP | ADP | ATP |
|---|---|---|---|
| *A.* Nuclei prepared by Behrens' method*<br>Whole thymus tissue* | 19·0<br>20·6 | 4·5<br>5·7 | 2·2<br>2·4 |
| *B.* Nuclei prepared in 0·25 *M* sucrose (isolation requiring 45 min.) | 9·3 | 7·7 | 14·0 |
| *C.* 'Sucrose' nuclei after rapid isolation (25 min. at 2° C.)<br>Above nuclei stirred gently at 2° for 60 min. after isolation | 19·0<br>3·5 | 10·5<br>5·7 | 7·6<br>24·5 |
| *D.* 'Sucrose' nuclei prepared in $10^{-4}$ *M* sodium cyanide<br>'Control' nuclei prepared without cyanide | 21·5<br>8·5 | 4·9<br>6·3 | 2·5<br>19·1 |
| *E.* 'Sucrose' nuclei prepared in $2 \times 10^{-4}$ *M* dinitrophenol<br>'Control' nuclei prepared without DNP | 20·1<br>8·6 | 8·0<br>5·6 | < 1·1<br>15·0 |

* The predominance of nucleotide monophosphate in thymus tissue and in thymus nuclei prepared by the Behrens' procedure should not be taken to indicate the actual conditions *in vivo*. It is probable that the predominance of these low-energy forms is simply a reflexion of anoxia resulting from the death of the animal. Evidence to support this conclusion stems from the nucleotide analyses of rat thymus which was frozen in liquid nitrogen immediately upon removal. In this instance the nucleotide triphosphates predominate over di- and mono-phosphates.

To test whether the synthesis of compounds lil adenosine triphosphate is an intranuclear phenomeno or whether it requires the participation of the cyt plasm, the following experiment was performe Nuclei were isolated as quickly as possible (25 mi at 2° C.). At this time, most nucleotides are st present as monophosphates (see Table 6). Tl isolated nuclei were then stirred gently in the co for an additional 60 min. At the end of the expe ment almost all the nucleotides had been convert to the triphosphate form. Since the conversion tak place in isolated nuclei, and occurs regardless of tl volume in which the nuclei are suspended, it appea that this is an intranuclear synthesis of high-ener phosphate. Only intranuclear adenosine monoph phate seems to be involved because added adenosi monophosphate is not acted upon. The results Table 6 also make it clear that the process is complete inhibited in the presence of $10^{-3}$ *M* sodium cyani or $2 \times 10^{-4}$ *M* dinitrophenol. However, it should l noted that certain reagents which block oxidati phosphorylation in mitochondria, namely, jan green *B* ($2 \times 10^{-4}$ *M*), methylene blue ($2{\cdot}5 \times 10^{-4}$ *M* and dicumarol ($10^{-4}$ *M*), have no effect on tl synthesis of adenosine triphosphate by isolat thymus nuclei. Synthesis of adenosine triphospha does not occur in the absence of oxygen. Tak together, the results indicate that nuclei are equipp with energy-generating systems which presumab operate via some type of oxidative mechanism. T relationship of this to the mitochondrial system being considered.

## Amino-Acid Incorporation by Lymphoma Cell Nuclei

The procedures described for the study of prote synthesis in isolated thymus nuclei have recent been extended to include another test syste Nuclei have been prepared from the cells of a tra plantable mouse lymphoma [*AKR* lymphoma *L* (This material was very generously given to us l Dr. John G. Kidd, of Cornell University Medic College.) The time-course of incorporation of $^{14}$ alanine by the lymphoma nuclei is included in Fig.

In summary, nuclei prepared from calf thymus a sucrose medium actively incorporate $^{14}$C-labell amino-acids. It has been shown that this is a sy thetic reaction which requires the participation the deoxyribonucleic acid of the nucleus. Therefo a biochemical function of deoxyribonucleic acid the synthesis of protein in the chromosome. The fr phosphate groups of the deoxyribonucleic acid do n seem to be involved in the process. When the protei of the nucleus are fractionated and then classifi according to their specific activities, one finds t histones to be relatively inert. The protein fracti most closely associated with the deoxyribonucle acid has the highest activity. A diffusible rib nucleoprotein complex is also active. Together wi earlier observations on the incorporation of ami acids by cytoplasmic particulates, these results sh at protein synthesis can occur in both nucleus and toplasm. It also follows that the nucleus can meet e energy requirements of protein synthesis. In this nnexion it has been found that the isolated thymus ıcleus is endowed with systems which generate gh-energy phosphate bonds. [July 26

# THE VENEZUELAN INSTITUTE FOR NEUROLOGY AND BRAIN RESEARCH

By DR. GEOFFREY H. BOURNE

London Hospital Medical College

ITUATED in the beautiful mountains surrounding Caracas, the capital of Venezuela, and only 12 km. vay from the centre of the city, is an Institute hich represents the first stage of a great scheme for urological research.

On January 1, 1955, the 5,000-ft. mountain on hich this Institute has been placed was virgin rritory; since then, the prodigious efforts of Dr. umberto Fernandez-Moran have resulted in the ıttening of the top of the mountain, the building an 800-kW. electric power station with specially ntrolled voltage, a water-supply system which cludes an artificial lake of some 6 million litres pacity, and what is described as the 'Pilot' unit of e Institute, together with residences for the staff. n December 2 this first section of the new Institute as being opened by the President of Venezuela, eneral Marcos Perez Jimenez, less than a year from the arrival of the first bulldozer on the mountain top.

This first stage of the plan has already cost three million dollars, but much more will be spent before the entire project is completed. This first part contains laboratories for research into nerve ultrastructure, neurophysiology, biophysics, biochemistry and biomathematics. In addition, there are a large library, several workshops and ten residential units for scientific personnel and assistants. A guest house for visitors from abroad is also incorporated into the design. Further development of the Institute envisages a large building for the Neurotropic Virus Research Unit, a large radiation laboratory which will be equipped with a nuclear reactor for medical research, and further buildings for biochemistry, biomathematics and experimental neuropharmacology. It is proposed ultimately to have a hospital of two

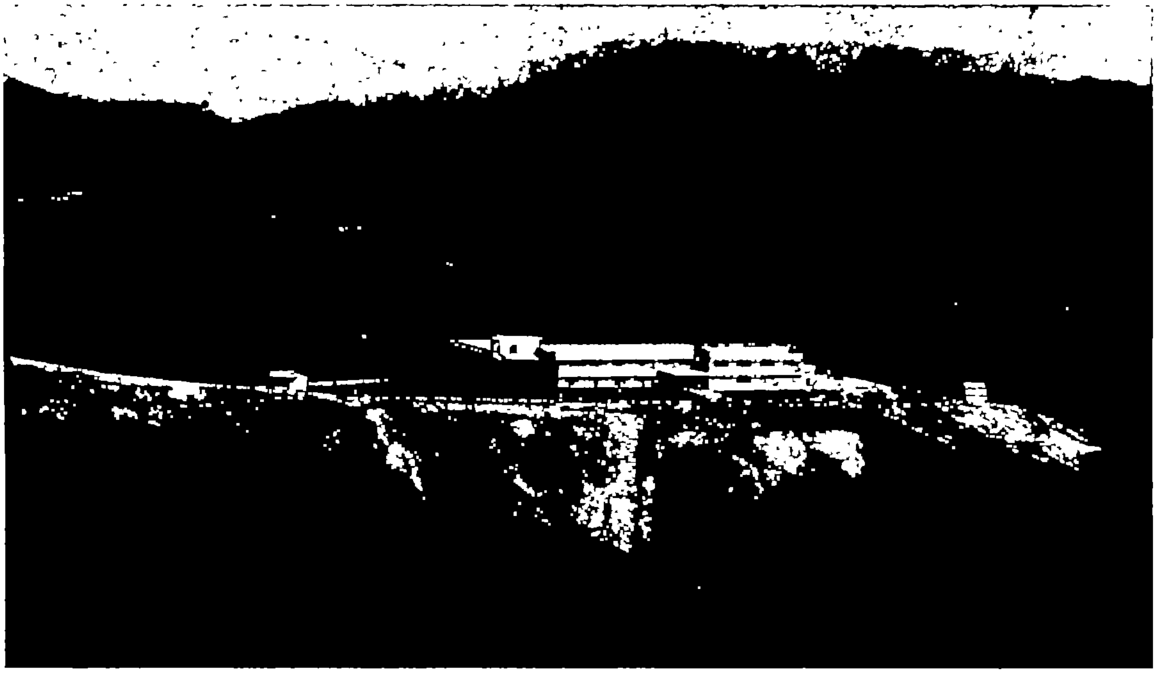

Fig. 1. The Venezuelan Institute for Neurology and Brain Research

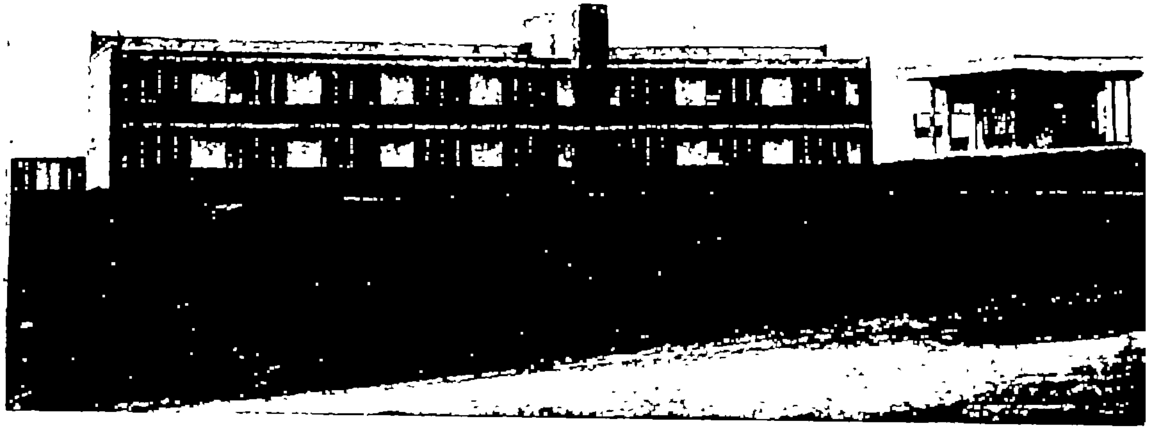

Fig. 2. First building of IVNIC (Venezuelan Institute for Neurology and Brain Research) containing: (1) Department of Nerve Ultrastructure (equipped with three electron microscopes); (2) Department of Neurophysiology; (3) Neurotropic Virus Research Unit; (4) Department for Nuclear Magnetic Resonance Studies; (5) Department of Biophysics; (6) Department of Biomathematics

hundred beds similar to the Research Hospital at the National Institutes of Health in Bethesda, U.S.A. In fact, the Institute was founded last year (April 29, 1954) by decree of the President of Venezuela as an autonomous government agency similar in status to the National Institutes of Health, and in many respects to the National Institute for Medical Research in Great Britain.

The object of the Institute goes beyond being simply a national institution; it is hoped that it will become a regional research centre in neurology in South America and eventually an international research and training centre in this field. In many respects it is strategically situated for this purpose, being only seven to eight hours away by aeroplane from New York and fifteen to eighteen hours away from Britain and Western Europe. Close contact with the United States has already been established by the signature on June 14 last of an agreement between the two countries under the terms of which the United States will furnish Venezuela and the Institute with certain radioactive materials and will supply information on the design, construction, operation and use of nuclear reactors for research. The U.S. Atomic Energy Commission, under the terms of this agreement, has also agreed to lease the Venezuelan Government up to 6 kgm. of contained uranium-235 in uranium enriched up to a maximum of 20 per cent uranium-235.

The proposed international character of the Institute has been emphasized by the first staff appointments: Dr. Gunnar Svaetichin, of the Karolinska Institute in Sweden, has already arrived in Caracas to take charge of the Department of Neurophysiology, which has been organized and equipped especially to work with the refined micro-electrode techniques with which Dr. Svaetichin carried out pioneer work in Sweden. In addition to this, a department devoted to the application of nuclear magnetic resonance technique to the study of para-crystalline biological components like the myelin sheath of nerves is being organized with the c laboration of Dr. P. Dennis, of the University Geneva. Full staffing of the various departments the Institute will be a slow process, and will obvious have to be carried out with care. Those who do to the new Institute may well find that the perpetu springlike climate of the mountain-top, on which t Institute lies, the feeling of peaceful detachme from the world engendered by a mountainous habita the congenial colleagues and lack of financial worr provided by a generous salary, will provide a uniq atmosphere in which their hypotheses and theori can be thought over, discussed and finally put the test.

Providing an adequate library for the staff is problem which the Institute will need to solve. Ba numbers of many journals would be difficult obtain; but it is proposed for this purpose to bu up a collection of microfilms of back numbers. T policy of the library will also be to invest in curre journals rather than books, since books are stat rapidly becoming out of date, whereas journals a the life-stream of advancing knowledge. The equi ping of the Institute will also be important; b donors have been generous for this purpose, and t researches on fine structure of nerves will have t benefit, for example, of three electron microscopes.

A description of this remarkable new Institu would be incomplete without some reference to i initiating genius and first director, Dr. Fernande Moran. Dr. Fernandez-Moran graduated in medici in Munich and later re-qualified at the Centr University, Caracas. Afterwards he took a Ph.D. physics in the University of Stockholm. He was fellow in neurology at George Washington Universit Washington, D.C., assistant in neurosurgery at t Serafimerlas Clinic, Stockholm, and Research Fello at the Institute for Cell Research, Karolinsk Institute, Stockholm, and assistant professor of c research in the same Institute. As well as being t first director of the new Institute, he holds the cha biophysics at the Central University, Caracas. is electron microscope studies have established his putation as an authority on the sub-microscopic ganization of vertebrate nerve fibres. Much of this ork was due to his development of a microtome for tting sections of nervous and other tissues (in- uding undecalcified bones and teeth) at thicknesses 100 A. or less, which are necessary for good elec- on microscope investigations. For this machine he so designed a diamond knife which could be made om industrial diamonds. In the Institute, Dr. ernandez-Moran will take charge of the work on ne structure of nervous tissue, and he has estab- ished a special department to continue the develop- ent work on the diamond knife and on microtomes use with them.

During my visit to the Institute last summer, it as a revelation to see the energy and speed with hich Dr. Moran tackled and coped with the in- umerable details of equipping and starting the istitute in time for the opening.

Venezuela is in an extremely fortunate financial osition due to the exploitation of her oil and other atural resources, and she is extremely fortunate hat she has at such a moment someone like Dr. ernandez-Moran, who was able to conceive and to recute such a remarkable scheme, and an enlightened inister of Health and President, who were far- ghted enough to see that money invested in this ay would benefit not only Venezuela itself but ltimately the rest of the world as well. The Vene- elan Institute for Neurology and Brain Research a practical step forward in international scientific search.

# OBITUARIES

## Dr. J. W. Nicholson, F.R.S.

DR. J. W. NICHOLSON, an outstanding mathe- atician and man of science, died on October 10, ged seventy-three. He was the eldest son of the te J. W. Nicholson, of Redcar, Yorkshire, and egan the serious study of mathematics and physical ience at the University of Manchester. Later, he itered Trinity College, Cambridge, where his rilliant career began. He was 12th Wrangler in 904 and Isaac Newton Student in 1906. In 1907 he as Smith's Prizeman. He was Adam's Prizeman wice—in 1913 and 1917. He lectured at the avendish Laboratory and later at The Queen's niversity, Belfast.

In 1912 he was appointed professor of mathe- atics in the University of London, King's College, nd occupied this chair until 1921, when he became itor at Balliol College, Oxford, where he was irector of studies in mathematics and physics until rious illness forced him to retire in 1930.

Nicholson was one of the most brilliant mathe- aticians and astrophysicists of his time. In 1917 e was elected into the Royal Society. He was also Fellow of the Royal Astronomical and the London athematical Societies, past president of the Röntgen ociety, a former vice-president of the Physical ociety and a member of the Société de Physique. e was an excellent lecturer and teacher, and prob- bly no teacher in King's College in his time was so uch appreciated and admired by his students and olleagues as he was.

Nicholson's scientific achievements are much more nportant than is generally realized in these days: the elucidation of the electronic structure of atoms owes as much to Nicholson as to any other one man. Before his appointment to King's College, he became interested in certain nebular spectra (the nebula in Orion among others) and the spectrum of the solar corona; and the first of a most remarkable sequence of papers on this subject appeared in the *Monthly Notices of the Royal Astronomical Society* (72, 49; 1912), entitled "The Spectrum of Nebulium". In this he attributed certain nebular spectral lines to a primitive type of atom which he named nebulium. This he imagined to consist of a small central massive positively charged nucleus with four electrons travelling around it on the same circular orbit. He was thus enabled to account for certain spectral lines which, it seemed, could not be ascribed to hydrogen or helium. His work was inspired by Clerk Maxwell's famous paper on Saturn's rings. He was, in fact, able to identify a large number of nebular spectral lines with those which his nebulium would be expected to emit. Indeed, he *predicted* a nebular spectral line the wave-length of which he calculated to be 4352·9 A. before it was observed. It was later observed and measured by Prof. F. J. M. Stratton, who estimated it to be 4353·3 A.

Perhaps the most remarkable feature of Nicholson's work was the discovery that angular momentum is an integral multiple of $h/2\pi$. There is no doubt that this work inspired his pupil, Niels Bohr, to explore the consequences of assuming the hydrogen atom to have a single electron travelling in a circle around a massive nucleus, and it was certainly part of the inspiration of the $\int pdq = nh$ condition enunciated by one of his colleagues at King's College and which was later adopted by Bohr.

One must not omit to mention the important work in which Nicholson collaborated with the distinguished spectroscopist, Sir Thomas Merton, and which was published in the *Philosophical Transactions of the Royal Society* (A, 216, 459; 1916; A, 217, 237; 1917; and A, 220, 137; 1919). It dealt with the distribution of intensity in broadened spectral lines and with intensity relations in the spectra of hydrogen and helium.

Nicholson was a friendly and generous man who took great pleasure in being helpful to both students and colleagues. He was a man of high character and in that respect reminded me of our colleague, H. Stanley Allen, and of the great Max Planck. All of us who knew him were deeply distressed by his tragic illness. As a mathematician he impressed me as very sound, and I learned more from him than from any other man, with the exception, perhaps, of the German mathematician, Carl Neumann. I shall always treasure his memory.

Nicholson married Dr. Dorothy Wrinch, Fellow of Girton College, Cambridge, in 1922, and had one daughter; the marriage was dissolved in 1938.

WM. WILSON

## Mr. Alexander Keiller

ALEXANDER KEILLER, who died at the end of September at the age of sixty-five, was one of the long line of distinguished amateur British archæologists which goes back to Aubrey and Stukeley. Of these perhaps the greatest was Pitt-Rivers, on whom Keiller, like him with leisure and abundant means at his disposal, admittedly modelled his own work.

While still in his early thirties, Keiller carried out a systematic survey of stone circles and allied monuments in north-east Scotland, making accurate plans and detailed descriptions of each site. A summary account of this work was presented as a paper to the British Association at its Aberdeen meeting in 1934.

In 1925, however, he embarked on the programme of excavation and field-work with which his name will be inseparably associated. He acquired and began excavations on Windmill Hill, near Avebury in north Wiltshire, and continued these annually until 1929, revealing in detail the first extensive Neolithic settlement to be explored in Britain. The material was housed in a museum in his London house, where it was at the disposal of students, and as a result the earliest Neolithic culture of southern Britain, taking its name from the type-site, was defined and clarified.

From Windmill Hill to the Avebury monuments themselves was an inevitable step, and in 1933 Keiller began a systematic excavation programme with the examination of the northern part of the West Kennet Avenue, continuing until 1938 within the Great Circle itself. He moved his residence to Avebury Manor, and re-housed his museum within its grounds, making it and the excavated portions of the monument available to the public. He adopted a policy of imaginative but judicious conservation and restoration of the Avebury monuments, and systematically purchased land to preserve these and their surroundings; as a result it was eventually possible for the whole area to be acquired by the National Trust and the Ancient Monuments Department of the Ministry of Works.

Keiller's outstanding contribution to contemporary British archæology was his insistence on high standards of discipline and accuracy in excavation and field-work, and his realization from the first of the value of scientific techniques as applied to archæological material. He early appreciated the potentialities of air photography, collaborating with Crawford in the "Wessex from the Air" survey, and even discussing with Eckener the possibility of using the *Graf Zeppelin* for a similar but even more ambitious scheme. At Windmill Hill he insisted on a full study of the faunal and floral remains in their archæological context. But above all it is to Keiller that we owe the inception of the systematic study of British prehistoric stone artefacts by petrographical means, which, following his lead, is now yielding information of the highest importance on manufacture and trade in the early second millennium B.C. Alec Keiller was an enthusiast in the best sense; full of ideas, stimulating and highly individual. Archæology, like other academic disciplines, can only benefit from the impact of such men.

STUART PIGGOTT

## Dr. E. J. Delporte

DR. E. J. DELPORTE, who died at Uccle on October 19, was honorary director of the Royal Observatory at Brussels, where he had continued to work since his retirement from the directorship in 1947.

Eugène Joseph Delporte was born in Brabant in 1882, and after studying mathematics and physics at the University of Brussels, obtained the degree of D.Sc. with distinction in 1903, entering the Observatory in the same year. In 1923 he took charge of the equatorial instruments and began that p gramme of minor planet observations which was become his main interest. It was during this peri that Delporte proposed that new boundaries shou be adopted for the constellations, defined in terms hour circles and parallels of declination. The propo was accepted by the International Astronomi Union in 1928, and the work was completed in 19 Originally intended to apply only to constellatio north of 12·5° south declination, the scheme fina covered the sky from pole to pole, the northe boundaries merging well with those which Gould h previously defined for the southern hemisphere.

In 1936 Delporte was appointed director of t Royal Observatory at Brussels, and pursued vigorous policy of systematic observations of t minor planets. It is impossible to estimate t number of new discoveries that were made duri these years, but some dozens of these minor plane have received permanent numbers. Planet 12 carries Delporte's name, as does the comet 1941 VI but he will probably be best remembered as t discoverer of the two remarkable asteroids Am (1221) and Adonis, the orbits of which are st exceptional in a list of more than 1,600.

Delporte worked enthusiastically for the Inte national Astronomical Union from its first meeti in Brussels in 1919, and played a prominent part Commission 20 (minor planets, comets and satellites of which he was president during 1938–48. H received many decorations from the hands of h countrymen, and was an active member of man scientific societies with astronomical interests. H was a corresponding member of the Bureau d Longitudes and of the Paris Academy of Science and in 1946 was elected an associate of the Roy Astronomical Society.

Conscious always of the needs of his Observator Delporte was mainly responsible for the improv ments which were effected in 1930, on the occasio of the centenary of the independence of Belgium when a 1-metre reflector, a double astrograph and new meridian circle were added to the equipmen Always ready to praise the scientific success of h colleagues, he gave every encouragement to th younger members of his staff, who will long rememb him as a remarkable observer and a wise and friendl counsellor.

J. G. PORTER

## Prof. Robert P. Bigelow

THE death occurred on September 6 of Pro Robert P. Bigelow, who retired in 1933 after fort years service in the Biology Department of th Massachusetts Institute of Technology; he wa ninety-two years old. A native of Baldwinsville, Ne York, Dr. Bigelow graduated from Harvard Unive sity and received the degree of doctor of philosoph at Johns Hopkins University before joining th staff of the Massachusetts Institute in 1893 as a instructor. He was appointed assistant professor zoology and parasitology in 1912, associate profess in 1915, and professor in 1922. Following his retir ment, Dr. Bigelow served as honorary lecturer in th Biology Department; and, in 1944, returned as special lecturer. He was librarian of the Institut during 1895–1925. Dr. Bigelow was also the form librarian of the Marine Biological Laboratory Woods Hole, and editor of the *American Naturali* and the *Technology Quarterly*.

# NOBEL PRIZES FOR 1955

THE following awards of Nobel Prizes to scientific men have been announced:

## Physics: Profs. P. Kusch and W. E. Lamb

The joint award of the Nobel Prize for Physics for 955 to Prof. P. Kusch, of Columbia University, and rof. W. E. Lamb, of Stanford University, recognizes common feature in their contributions to physics. oth have applied the methods of high-precision dio-frequency spectroscopy to atomic phenomena, which the effect on the electrons of their own diation field, though very small, is significant.

Prof. Kusch has applied the methods of radio-equency resonance in atomic and molecular beams determine, with the highest achievable precision, e magnetic moment of atomic nuclei, and of the ectron. In this way he has shown that the spin-oment of the electron is not precisely one Bohr agneton, but (1·001146 ± 0·000012) Bohr mag-etons. Modern theories, developed at about the ame time, and greatly stimulated by the experi-ental work of Kusch and of Lamb, predict the alue $1 + e^2/\hbar c - 11{\cdot}89\, e^4/\hbar^2c^2 + \ldots = 1{\cdot}00114536$. usch's measurements of nuclear magnetic moments, om nuclear resonance, and from atomic hyperfine tructure, show small but significant discrepancies hich throw light on the structure of atomic nuclei.

Prof. Lamb, while primarily a theoretical physicist, as turned to experiment to test the prediction of odern theories of quantum electrodynamics, that he fine structure of the hydrogen spectrum is odified by the reaction of the electron with its adiation field. According to the simple Dirac wave quation, the energy of the metastable $2s_{\frac{1}{2}}$ level of ydrogen is exactly equal to the energy of the $2p_{\frac{1}{2}}$ vel. In an experiment where transitions are induced etween these two levels in an atomic beam, Lamb emonstrated that they are separated by 1057·77 ± ·10 Mc./s. Modern theories predict 1057·19 ± ·16 Mc./s.

Prof. Lamb has recently accepted appointment to he chair of theoretical physics in Oxford.

## Physiology and Medicine: Prof. Hugo Theorell

The Nobel Prize for Physiology and Medicine for 955 has been awarded to Prof. Hugo Theorell, irector of the Biochemical Department of the edical Nobel Institute of Stockholm, for his work n flavoprotein enzymes and hæmoproteins such as ytochrome *c*, peroxidase, catalase and myoglobin. he study of the "old flavoprotein enzyme", the rosthetic group of which is flavin mononucleotide FMN), was carried out by him when he was holding Rockefeller Foundation Fellowship at the Kaiser Vilhelm Institute (now Max Planck Institute) for ell Physiology (Berlin-Dahlem). It is the electro-horetic separation of this enzyme from a poly-accharide, which accompanied it, that enabled him o purify this enzyme and to determine its main roperties. Of special interest, however, is his exten-ive study of cytochrome *c*, the extractable and oluble component of the cytochrome system which onstitutes the intracellular respiratory chain of atalysts linking the dehydrogenase systems with molecular oxygen, thus providing the essential path for hydrogen or electron transfer from the activated molecules of substrates to oxygen. To the study of the physico-chemical properties of cytochrome *c* and other hæmoproteins, the mechanism of the reactions in which they are involved and the nature of the links between their prosthetic groups and protein, Prof. Theorell has applied great technical skill and a variety of modern physico-chemical and biochemical methods.

More recently, Prof. Theorell and his co-workers studied the properties of alcohol dehydrogenase extracted and purified from liver, and they were able for the first time to follow spectrophotometrically the kinetics of reactions between the enzyme and the reduced co-enzyme I (diphosphopyridine nucleotide). From this work emerged a method for the precise estimation of minute amounts of alcohol, which is of great value for medico-legal work. Prof. Theorell has established a very active centre of research which attracted many workers from different countries to his department which, in 1948, was transferred to the new building of the Medical Nobel Institute, where it is provided with all facilities for the study of a great variety of biophysical and biochemical problems.

## Chemistry: Prof. Vincent du Vigneaud

This year's Nobel Prize for Chemistry goes to Prof. Vincent du Vigneaud, professor and head of the Department of Biochemistry, Cornell University Medical College, New York. Prof. du Vigneaud had many achievements to his name before his recent outstanding work on the structure and synthesis of oxytocin and vasopressin. His researches on the chemistry of insulin were a valuable early contribution in this difficult subject, and were naturally related to his studies on intermediary metabolism and sulphur-containing substances. A distinguished series of investigations on the mechanism of transmethylation and the biosynthesis of choline were based on his substantial experience of both chemical and biochemical methods and greatly added to our knowledge of the metabolism of methionine and of cystine. During the Second World War, Dr. du Vigneaud turned his attention to the chemistry of penicillin, and his synthesis of this substance was a significant contribution to this subject. More recently his activities, and those of his colleagues, have been largely directed to the isolation, chemistry and synthesis of the posterior pituitary hormones, oxytocin and vasopressin. The demonstration that these substances are closely related octapeptides, each containing a disulphide bond spanning six amino-acid residues (a type of structure also found in insulin by Sanger), and the fact that, as long ago as 1935, du Vigneaud had shown that oxytocin can be reduced and reoxidized without obvious inactivation, paved the way to the synthesis of both of these hormones. Each step in a series of complex investigations has been checked with the utmost care, and the complete synthesis of these two related substances has opened wide the door to vast new developments in the pharmacology of peptide hormones and their chemical relations.

# NEWS and VIEWS

## Wellcome Laboratories of Tropical Medicine, London : Brigadier J. S. K. Boyd, O.B.E., F.R.S.

Brigadier J. S. K. Boyd has resigned his position as director of the Wellcome Laboratories of Tropical Medicine as from January 1, 1956, on his appointment as a Wellcome trustee in place of Prof. T. R. Elliott, who has retired. Brigadier Boyd joined the Royal Army Medical Corps in 1914 and served in France, Macedonia and India. In 1929 he carried out researches in India on a variety of pathological problems. Returning to England, he was principally responsible for the official adoption of immunization with tetanus toxoid in the Army, a practice which was almost to eliminate casualties from tetanus during the Second World War. During the War he was deputy director of pathology to the Middle East Forces in Egypt, where he was concerned with the organization of blood transfusion services and the many pathological problems arising in a subtropical climate. Among these problems the introduction of sulphaguanidine, in collaboration with Sir Neil Hamilton Fairley, for the treatment of bacillary dysentery was outstanding. He became deputy director of pathology to 21 Army Group in 1944 and served in that capacity in Western Europe until 1945, when he became director of pathology to the War Office. In 1946 he resigned this position to accept appointment as director of the Wellcome Laboratories of Tropical Medicine, where he has since organized chemotherapeutic research in the tropical field. In spite of the heavy administrative work of an army pathologist, Brigadier Boyd always found time to carry out his own particular research and has continued to do the same in his recent appointment. His most important work has dealt with the analysis of the multiplicity of antigens in the group of the dysentery bacilli, and with bacteriophages, particularly with the problems arising from the existence of symbiotic phages. In both these fields he has gained an international reputation. He was elected F.R.S. in 1951 and F.R.C.P. soon afterwards. It is fortunate that his new appointment will not prevent him from continuing his researches.

## Dr. R. S. F. Hennessey, C.M.G.

Dr. R. S. F. Hennessey, who succeeds Brigadier Boyd, recently retired from the Colonial Medical Service, in which he has spent twenty-five years. He received his medical education at Trinity College, Dublin. Primarily a pathologist, he was employed as such by the Uganda Government from 1929 until 1944, and during most of that time he was lecturer in pathology and forensic medicine at Makerere College Medical School. From 1944 he served for three years with the Palestine Government, first as deputy director of medical services (laboratories) and later as deputy director of medical services (health). Thereafter he became assistant medical adviser to the Colonial Office in London and a member of the Colonial Medical Advisory Committee. His most recent appointment, during 1949–55, was as director of medical services, Uganda Government, in which capacity he was a member of several research committees. Dr. Hennessey thus takes with him to his new appointment a sound background of administrative experience and a wide knowledge of the outstanding problems of tropical medicine.

## U.S. National Science Foundation

Dr. Alberto F. Thompson has been appointe head of the Office of Scientific Information of th U.S. National Science Foundation, and Mr. Clyde C Hall, public information officer of the Foundation Dr. Thompson goes to the foundation from the United States Atomic Energy Commission, where h has served for the past seven years as chief of technical information. He was in charge of the Unite States exhibit at the International Conference on th Peaceful Uses of Atomic Energy at Geneva. Befor the War, he was an assistant professor of chemistr at the Massachusetts Institute of Technology, an earlier, a member of the faculty of the University o Minnesota. Mr. Hall was special placement representative in the Civil Service Commission, with majo responsibility for the identification and placing o top management specialists in the Federal service During the War, he served as assistant to the Directo of Public Information for the Foreign Economi Administration and, earlier, as an informatio specialist with the U.S. Department of Agricultur Before that he was a staff writer for the *Nationa Geographic Magazine* and the Washington Bureau o the Associated Press.

## Nuclear Energy Committee of the Institute o Metals

The Council of the Institute of Metals has appointe a Nuclear Energy Committee, with the object o stimulating interest in metallurgical problems arisin in connexion with the industrial and scientific aspect of the use of nuclear energy. It is proposed that among its activities, the new Committee shall arrang special meetings, discussions and symposia ; invit the writing of papers or articles for publication ; an arrange the publication of books or other literatur to attain the objects for which it was formed. Th Committee hopes to arrange an exhibition of nuclea energy products, of interest to metallurgists, in connexion with the Institute's Spring Meeting in Apri 1956. The constitution of the Committee is : Mr G. L. Bailey (British Non-Ferrous Metals Researc Association), Mr. E. W. Colbeck (Hadfield, Ltd.), Dr Maurice Cook (Imperial Chemical Industries, Ltd. Metals Division), Dr. S. F. Dorey (Lloyd's Registe of Shipping), Dr. H. M. Finniston (United Kingdo Atomic Energy Authority), Dr. Ivor Jenkins (Th General Electric Co., Ltd.), Prof. A. G. Quarrel (University of Sheffield), Mr. L. Rotherham (Unite Kingdom Atomic Energy Authority), Mr. S. S. Smit (Imperial Chemical Industries, Ltd., Metals Division), and Major P. L. Teed (Vickers-Armstrongs (Aircraft), Ltd.). Anyone interested in the activities o the Committee should communicate with Lieut. Colonel S. C. Guillan, Secretary, Institute of Metals 4 Grosvenor Gardens, London, S.W.1.

## An Electronic Computer for the Meteorologica Office

This is the centenary year of the Meteorological Office, and through its long record meteorologists have been confronted with dynamical problems of such complexity that their solution has sometimes seemed beyond hope. In recent years, however, nothing less than a revolution has taken place. The analysis of regular upper-air observations has revealed much about the physical processes, and the invention of electronic computers has opened the way to numerical solutions to problems the analytical solutions of which are

hibitively difficult. The staff of the Napier Shaw
search Laboratory of the Meteorological Office
ve already made a major contribution in this new
vance and, confirming work in other countries,
ecially the United States and Sweden, have
wn that weather maps, giving isobars and upper
contours, may be predicted for 24 hr. ahead by
sic hydrodynamical methods and with promising
curacy. The numerical computations are extremely
avy and hitherto have been performed by arrange-
nt on digital electronic computers available in
ndon and Manchester. The requirement for a
achine for the sole use of the Meteorological Office
s, happily, now been recognized, and it is expected
at one of most modern type will be installed at
nstable within a year or so. Whatever may be
e future success of weather prediction, this step
ay be taken as marking a turning point in the
ience of meteorology. Other problems, not only
ose of forecasting, will no doubt yield ground to an
tack by quantitative methods, and the recent
aims made by the director, Sir Graham Sutton, for
eteorology as an exact science must more and more
realized.

## ience Service

SCIENCE Service was founded in America in 1921
a non-profit corporation with trustees nominated
the National Academy of Sciences, the National
esearch Council, the American Association for the
lvancement of Science, the E. W. Scripps Estate,
d the journalistic profession. In the original state-
ent of aims its task was defined as "to take science
the people . . . to conduct, operate and furnish
ess service for the collection, preparation, dis-
ibution and sale of scientific matter and information,
rrent events and fundamental conceptions or topics
interest to general readers, to newspapers, period-
als, journals, magazines, educational institutions
d government". One of its developments has been
e Science Clubs of America, an organization in
hich about 350,000 boys and girls are affiliated to
teen thousand clubs in the United States and
her countries. The clubs vary in size from three
seven hundred members, and programmes are
anned to suit the age and science interests of the
oup. Each year two national events are held for
embers of Science Clubs of America. The annual
ational Science Fair was started in 1950 and is held
ch spring in a different city. The host city in 1956
Oklahoma City and, in 1957, Los Angeles. The
her national event was started in 1942 and, as the
nnual National Science Talent Search, is held each
ear for seniors in high school who wish to compete
r 11,000 dollars in Westinghouse Science Scholar-
ips for their college education. The winners receive
free visit to Washington to attend the Science
alent Institute. All the brochures produced by
ience Service are set out attractively and may be
tained from 1719 N. Street, N.W., Washington 6,
.C.

## niversity of Birmingham

THE University of Birmingham has conferred the
tle of reader in mathematical physics on Dr. R. H.
alitz. The following have been appointed lecturers
the University: Dr. P. H. Rose (physics), S. W.
reen (botany), Dr. J. S. M. Botterill (chemical
gineering), J. W. R. Griffiths and J. C. Cluley
lectrical engineering), and Dr. H. Y. Yeung (electron
hysics). The following have been appointed to fellowships: Dr. C. B. B. Bull (geophysics), Dr. A. M. Bolsterli and Dr. E. Vogt (mathematical physics), D. B. Idle (botany), Dr. R. A. James and S. Markowitz (physics), Dr. Eleanor H. Slifer (zoology), and Audrey Todd (chemistry).

Gifts have been made to the University as follows: to the Department of Chemistry, £550 from the Electrical Research Association, for one year in the first instance, for research on the fundamental characteristics of the oxidation of certain liquid hydrocarbons, and £700 rising to £850 over three years from S. C. Johnson and Co. for a research fellowship to be devoted to research on waxes; to the Department of Civil Engineering, two grants from the Highway Engineering Education Trust, one for establishing a lectureship in highway engineering for a period of three years and the other, amounting to £250 a year for two years, for the organization of a summer school to give advanced training in road construction, traffic engineering and highway soil mechanics; to the Department of Electrical Engineering, £800 from the Central Electricity Authority to continue research work on electrostatic precipitation of dust; to the Department of Chemical Engineering, £935 for one year from the Ministry of Supply for research on the low-temperature properties of esters, £600 a year for two years from Whiffen and Sons, Ltd., for research in liquid-phase corrosion, £3,675 over a period of three years from the United Kingdom Atomic Energy Authority for research on the characteristics of 'Spraypak', and £775 from the Ministry of Supply for research on the design of distillation towers; and to the Department of Physical Metallurgy, a total grant of £3,225 for three years from the United Kingdom Atomic Energy Authority for research on the properties of ionic crystals.

## University of Leeds: Recent Gifts

THE following gifts have been made to the University of Leeds: £1,000 from Glover and Main, Ltd., London, for North Block I (Fuel Science) of the University; 6,000 dollars from the Dow Chemical Co., Michigan, to the Department of Physical Chemistry for further research in paramagnetic resonance; £6,627 from the Wool Textile Research Council to the Department of Textile Industries for research under the direction of Prof. J. B. Speakman and £3,340 for 1955–56 for research under the direction of Prof. A. H. Nissan; £900 from the Wool Textile Research Council to the Department of Colour Chemistry and Dyeing for research; and £900 for 1955–56 from the Cement and Concrete Association to the Department of Civil Engineering for the salary of a lecturer.

## National Institute of Sciences in India: Proceedings

THE National Institute of Sciences in India, since its inception in 1935, has published regularly every year the *Proceedings of the National Institute of Sciences in India*, containing miscellaneous articles on physical and biological sciences, as well as important official proceedings of the Institute. The Council of the Institute has decided that, with effect from Vol. 21 (1955), the *Proceedings* are to be published in two parts—*A*, physical sciences; *B*, biological sciences—and they are to be issued bi-monthly in alternate months. In addition, the official proceedings are to be published in a "Year Book", an annual publication on the lines of the publications of the Royal Society. The volume and year numbers will be the same for the two parts of the *Proceedings*, and each will contain its own title page, page numbering and index.

## Science Masters' Association : Annual Meeting

THE annual meeting of the Science Masters' Association will be held in the Royal College of Science, Imperial Institute Road, South Kensington, London, S.W.7, during December 28–30, the annual business meeting of the Association being on the last day. The president this year is Sir Edward Salisbury, director of the Royal Botanic Gardens, Kew, and he will deliver his presidential address in the Courtauld Hall, Queen Elizabeth College, on the evening of December 28, his subject being "Science and Education". Two special discussions will be held: one on December 30 at which science teaching in secondary modern schools will be considered; and one on December 31 on first-year failures in the universities, which will be introduced by Dr. E. R. Roberts, of the Department of Inorganic Chemistry, Royal College of Science, and by Prof. F. A. Vick, of the Department of Physics, University College of North Staffordshire. On the morning of December 29 a lecture-demonstration of experiments with radioactive isotopes suitable for schools will be given by the members of the Radioactivity Subcommittee of the Association, and in the afternoon there will be a demonstration of ciné and cinémicrography in the teaching of natural history, given by K. A. Murch, of the Chichester High School for Boys. In the afternoon of December 30 the Science and Religion Group of the Association will hold a discussion, and in the evening Mr. T. D. Bourdillon, a member of the 1953 Everest Expedition, will lecture on the successful conquest of Mount Everest and on the use of oxygen during the climb, which was his special responsibility. As in the past, manufacturers and publishers who advertise in the *School Science Review* will exhibit at the meeting, and the usual exhibition by members of apparatus and teaching aids which they have found useful will also be held. In addition, special displays will be given in the Royal College of Science by the Civil Defence Department of the Home Office, and in Queen Elizabeth College by members of the Science Departments there. Further information can be obtained from the annual meeting secretary of the Association, W. H. Dowland, 93 Westbourne Road, West Hartlepool, Co. Durham.

## British Institute of Radiology : Annual Congress

THE annual congress and exhibition of the British Institute of Radiology will be held in Caxton Hall, Victoria Street, Westminster, London, S.W.1, during December 8–9. On the morning of the first day, an opening address will be given by Sir John Cockcroft, director of the Atomic Energy Research Establishment, on the future role of atomic energy in industry, science and medicine, and this will be followed in the afternoon by a symposium on the hazards from the increasing use of ionizing radiations, at which three papers will be read. In the evening Dr. Gwen Hilton (University College Hospital, London) will deliver the Mackenzie Davidson Memorial Lecture and will speak on the role of radioiodine in the treatment of carcinoma of the thyroid. The second day will be devoted to papers on the clinical applications of image intensification, and three symposia as follows: pulmonary fibrosis and collagen diseases of the lungs; the influence of histological structure on radiosensitivity; the introduction of the rad in radiotherapy practice. The fee for the congress is 1 guinea (10s. 6d. f members of the Institute). Further information c be obtained from the Honorary Secretary of t Institute at 32 Welbeck Street, London, W.1.

## Christmas Lectures for School Children

A CHRISTMAS lecture for older school childre arranged by the Institution of Electrical Enginee will be given at the Institution (Savoy Place, Londo W.C.2) on December 29 at 3 p.m., and again on t following day, by Mr. R. Brooks, his subject bei "Electric Traction". The lecture will outline t principal features and methods of operation of t different systems of electric traction now in u particular reference being made to the equipment the locomotives and motor-coaches used on mai line and suburban services. The main principles electric railway signalling will also be considere together with a demonstration of full-size apparat including searchlight-type signals. Admission to t lecture is free, and application for tickets, stating f which afternoon they are required, should be ma to the Secretary of the Institution at the abo address. The Royal Institution's Christmas lectur this year will be the 126th such "Course of six lectur adapted to a Juvenile Auditory". The course w be given by Prof. H. W. Melville at 3 p.m. c December 27, 29 and 31 and January 3, 5 and 7, h subject being "Big Molecules". The topics to be di cussed at the six lectures will be, respectively, t making of big molecules, the size of a big molecul rubber and the rubber-like state, man-made fibre and plastics from big molecules (two lectures). F non-members of the Royal Institution, the fees f the course are: children (10–17 years) £1, adul £2. Application for tickets should be made to t Royal Institution, 21 Albemarle Street, London, W.

## Announcements

SIR GEORGE LLOYD-JACOB, one of Her Majesty' Judges of the High Court of Justice, has accepte appointment as a Trustee of the Ciba Foundation f the Promotion of International Co-operation i Medical and Chemical Research.

THE University of Sheffield has conferred the titl of emeritus professor of engineering on Prof. H. W Swift, and that of emeritus professor of glass technology on Prof. H. Moore, both of whom have recentl retired from their respective chairs.

THE Department of Scientific and Industri Research has appointed Sir Walter Drummon formerly chairman of the National Coal Board, an Prof. N. F. Mott, Cavendish professor of physics i the University of Cambridge, to be the Department' visitors to the Electrical Research Association, i succession to Dr. P. Dunsheath and Prof. J. T Randall, whose period of service has been completed.

THE Mond Nickel Co., Ltd., has appointed D G. L. J. Bailey to be superintendent of its Platinu Metals Research Laboratory at Acton, London N.W.10, in succession to Dr. E. C. Rhodes. D Bailey, who is a graduate of the Imperial College o Science and Technology, London, was on the staff o the Admiralty Engineering Laboratory, West Drayton, throughout the Second World War, and sinc 1945 he has been a member of the British Non Ferrous Metals Research Association, where he is a present deputy research manager.

# CONFERENCE OF COMMONWEALTH SURVEY OFFICERS

THE Commonwealth Survey Officers' Conference was held in London and Cambridge during .ugust 15–26. It was opened by Lord Lloyd, Under-ecretary of State for the Colonies, in the Depart-ent of Geography at Cambridge, and was attended y about two hundred representatives of Home and ommonwealth surveying departments and allied terests, including the directors of survey or sur-eyors-general of nearly all the Commonwealth rritories, with observers from the United States of merica, France, Holland, Belgium, Ireland and the udan. Between August 15 and 23, twenty-six apers were read on a wide variety of technical and dministrative subjects, after which the Conference oved to London for visits to neighbouring govern-ent survey establishments. Brigadier M. Hotine, irector of Colonial surveys, was president of the onference. Delegates were mostly accommodated Pembroke and Downing Colleges, a very con-enient arrangement. A valuable adjunct was an xhibition of surveying instruments by eighteen ritish manufacturers.

Of the papers read, eight dealt with administration, ducation and land registration; three with the esign of new instruments; eight with the routine f field surveying, nearly all from the point of view f air survey; three with the geodetic framework; ne with variations of sea-level; and three with lectronic aids to surveying. The list of titles might uggest that an aircraft and a box-full of electronics now a good substitute for hard work on the ground; ut in one of the discussions it was well agreed that most circumstances the best map could still only e made by a fairly equal combination of both pro-esses. The following notes give a short summary of he papers most likely to be of interest to readers of *ature.*

In a paper on the use of automatic plotting achines for 1/1,250 air survey, Major D. V. Hutchin-on described the combination of air and ground urvey now being used for the city survey of Oxford, hich will probably serve as a model for similar plans hroughout Great Britain. The air-photo plotting achine requires less dense ground control than the ld method of chain survey on the ground, but does ot, of course, provide a map which can be accepted ithout ground verification and amplification. Clear iagrams of a sample plan show the amount of detail about half) which is confidently identified on the hotograph and plotted by the machine, and how uch is left to be verified and amplified by the round surveyor: at this scale, buildings with over-anging eaves come into the latter category. The ut-turn of the ground surveyor has been increased rom 0·28 sq. km. a month without preliminary air urvey to 0·48 sq. km. with it. Total costs, including hat of flying, are substantially lower than when round survey alone is employed.

Prof. E. H. Thompson's new air-photo automatic lotting machine, of which the first model has just een completed by Messrs. Hilger and Watts, was on iew and was the subject of a paper.

A paper by Major I. E. Sleep analysed the accuracy f a 1 : 25,000 map made by multiplex equipment rom 1/90,000 vertical photography, supplemented by 1/30,000 obliques, taken from an aircraft at 45,000 ft., an altitude at which flying may be convenient in time of war. With ground control-points about 11 miles apart, errors of height were found to average 16 ft. and of position 12 metres, a standard which is adequate for a military 1/25,000 map with 20-metre contours, and which is indeed remarkable considering the scale of photography and scarcity of control. A typical 1/25,000 map sheet made in this way accompanies the paper, with the Ordnance Survey version (errorless in plan, but not in contouring) printed in grey, and the air-survey version in brown.

Surveyors will be interested to learn from a paper by E. W. Taylor that the designers of the new small Tavistock theodolite have changed over to the coincidence system of reading, and that both circles are now read in a single eyepiece alongside the main telescope. In the geodetic model, a similar coincidence system is also being adopted; but the separate micrometers and eyepieces for the horizontal and vertical circles are retained.

Commander W. I. Farquharson read a paper containing interesting descriptions of tidal bores, seiches, surges and secular changes of sea-level. From British tidal records, which are regrettably scanty, he has analysed the secular rises of sea-level during 1835–95, 1895–1925 and 1925–50, and finds them to be zero, 0·4 ft. per century and 0·5 ft. per century, respectively. He quotes rises of 0·4 and 1·2 ft. per century for the two later periods from American records at Halifax, New York and Baltimore, and a similar value from Holland. He suggests that port engineers should be prepared for a further rise of 1 ft. during the coming century.

Capt. C. C. Lowry's paper on radio aids to hydrographic surveying described the uses and limitations of radio distance, depth and direction measuring apparatus as applied to hydrographic survey, and a paper by C. Powell gave details of the construction, use and accuracy of the Decca equipment.

A paper by D. L. Mills, of the United States Army Map Service, described the completion of the African Arc of the 30th meridian. This great piece of geodetic triangulation, which was begun about seventy years ago, has been finally completed since 1952 by a party from the U.S. Army Map Service observing the section between latitudes 1° and 10° north. This section includes 300 miles of the flat Sudd region, where triangulation is difficult and has only been made possible by using 100-ft. portable Bilby steel towers. Three base-lines were measured by the Sudan Survey Department, and Laplace azimuth stations were observed at appropriate intervals.

One paragraph in this report answers a question which has often troubled surveyors, namely, what happens when a Bilby tower collapses. One such accident occurred, a tower collapsing with five men at the 100-ft. level. One broke a bone in his foot and the others were at work again after a day's rest. The ground was hard-baked clay. The Sudanese are evidently resilient.

The completion of the African arc, coupled with the radar connexion recently observed between Crete and Egypt, makes it possible (if desired) to compute

South African triangulation in terms of the European Datum. Russian triangulation, known to exist but not published, could carry the same datum to Vladivostok, and a gap of 1,000 miles in Persia is all that prevents it extending to Singapore. Radar measures, of geodetic accuracy, between Europe, Greenland and America will link the European and American datums within a few years, and triangulation from the latter already extends well into South America. The days of separate, isolated national surveys are passing.

A paper by H. A. Stamers Smith gave a useful summary of the present state of geodetic triangulation in Nigeria, where primary traverse has in places been very successfully used as a substitute for triangulation. The misclosures of ten such traverses are given, averaging about 1 in 100,000 in distances of 100–200 miles.

A paper by Col. R. C. A. Edge described work done by the Ordnance Survey with electronic computing. Traverse and levelling computations are a heavy item in the ordinary work, but, varying much in detail, require a high proportion of 'arranging' for pure computation. They are therefore more suited to punch-card methods using a small calculator (such as the *I.B.M.* 626) than to a large storage computer. An *I.B.M.* 626 has recently been installed at the Ordnance Survey. Photogrammetric computations, another heavy item, are more uniform but mathematically more complex. They are suitable for a large computer, and for some time they have been programmed for, and successfully computed by, *ACE*. They are now being programmed for *DEUCE*.

Space does not admit mention of the remaining papers, but all are of value in their own spheres. These Survey Conferences are held at four-yearly intervals, and provide a most welcome opportunity for surveyors from all over the Commonwealth to exchange ideas and to renew friendships. The papers presented at previous conferences, and the resulting discussions, have been published by H.M. Stationery Office, and it is hoped that a 1955 volume will soon be published also. G. BOMFORD

---

# INTERNATIONAL BIOMETRIC SYMPOSIUM IN BRAZIL

THE Biometric Society, which now forms the Biometric Section of the International Union of Biological Sciences, is endeavouring to stimulate the teaching and use of good statistical practices in biology in many parts of the world. As part of this programme, an international biometric symposium was held in Campinas, Brazil, during July 4–9. The University of São Paulo was host to the symposium, and a committee of the University Seminario de Estatistica, with Dr. C. G. Fraga (Institute of Agronomy, Campinas) as secretary, handled local arrangements; financial assistance was received from ten different governmental and non-governmental organizations. The ninety-eight statisticians and biologists attending included sixty-two from Brazil, eight from other Latin American countries, fourteen from the United States, five from Great Britain, seven from other European countries, and two from Asia. The foreign visitors will long remember the hospitality of their Brazilian hosts.

The president of the Society, Prof. W. G. Cochra (Johns Hopkins University), took as the subject his address the 1954 trial of the Salk poliomyelit vaccine in the United States, focusing attention o the design of the investigation rather than upon th outcome. He said that in 'placebo areas' childre who received the vaccine were matched by contro receiving a similar injection of a placebo, while i other parts of the country the only controls wer younger and older uninoculated children. Th difference between case-rates in inoculated an control children was apparently greater in th placebo areas. His suggested explanation was the natural immunity was lower in the homes of childre whose parents consented to their inclusion i the trial, a consent necessary in the placebo area for all participators but elsewhere only for th inoculated.

In the afternoon, Sir Ronald Fisher (University c Cambridge) described the contribution of biometr to plant improvement, with special reference t experimental design, the analysis of genetic model involving large numbers of Mendelian factors tha cannot be individually identified, and classical Mendelian genetics. Prof. E. R. Dempster (Universit of California) then discussed genetic models i animal breeding. Shorter papers on biometrica genetics by Prof. F. G. Brieger (Agricultural College Piracicaba) and Dr. H. Kalmus (University College London) related to autogamic populations an heterotic genes in plant genetics and to cyclomorphosis, respectively.

Two sessions on experimental design were held o July 5. Dr. S. C. Pearce (East Malling Researc Station) showed that difficulties of adequate replication with perennial crops restrict the experimenter t very simple designs. A compensation is that relationships between many concomitant measurements ca be studied. He illustrated the balancing of treatments so that one set of trees can be used for tw or more consecutive investigations. E. Amara (Institute of Agronomy, Pelotas) discussed missin yields and other problems in the analysis of sugar-cane experiments. The design and analysis o coffee experiments at the Campinas Institute o Agronomy were reviewed by Dr. A. Conagin and Dr Fraga, who showed how modern design had improved the quality of information obtainable in research on this crop. In a more theoretical paper, Dr. F. Pimentel Gomes (University of São Paulo) spoke of the use o the Mitscherlich equation in analysing fertilize experiments on sugar-cane. In the afternoon, Mis G. M. Cox (University of North Carolina) surveyed recent work in the theory of experimental design; her paper was of particular interest for its mention of special designs for estimating optimal conditions, including the new category of rotatable designs. Dr. W. J. Youden (Bureau of Standards, Washington, D.C.) then gave a graphic account of how types o design developed by biologists are now assisting research on physical problems. With remarkable clarity and humour, he illustrated the adaptation of designs to situations in which the block size i predetermined; or, at most, two replications are wanted; or some treatments are to be chosen afte part of the experiment was complete; or in which instrumental drift is a serious factor. On the following day, during a visit to the Agricultural College a Piracicaba, members held a discussion on experimental design for perennial crops.

On July 7, Prof. P. G. Homeyer (Iowa State College) summarized experience on sources of variation in feeding experiments with chicken, cattle and pigs, and its use in designing new experiments; he emphasized particularly the danger of neglecting variation between pens. Dr. G. L. Rocha (Brazil) and Dr. G. O. Mott (Purdue University) reviewed the technique and interpretation of pasture experiments in Brazil and the United States, respectively, after which Prof. A. Linder (University of Geneva) described an experiment on the grazing times of cows permitted to choose between differently treated plots. In the afternoon session, on sampling techniques, Dr. M. H. Hansen (United States Bureau of the Census) discussed the control of errors of response in sample surveys. Recent work on the theory and practice of estimating fish catches around the Indian coast was then described by Dr. P. V. Sukhatme (Food and Agriculture Organization). Prof. J. Nieto de Pascual (Bureau of Statistics, Mexico) described a survey of national morbidity in Mexico, and Prof. W. L. Stevens (University of São Paulo) presented an account of recent work on the sample estimation of the coffee harvest, a problem complicated by a biennial cycle of bearing. The session ended with a paper from Dr. E. Cansado (Interamerican Statistical Centre, Santiago, Chile) on new proofs of theorems on sampling from a finite population.

After a morning visit to the State Institute of Agronomy at Campinas, the afternoon of July 8 was given to papers on bioassay. Dr. C. I. Bliss (Connecticut Agricultural Experiment Station) showed general methods for obtaining confidence intervals for estimates of relative potency, and then illustrated how these could be adapted to various assay techniques in the "U.S. Pharmacopeia". Dr. D. J. Finney (University of Aberdeen) presented five models relating to correlations of residual error and residual effects of previous doses in cross-over and single-subject assays, and explained the statistical analysis appropriate to various designs. Dr. P. Mello Freire (Institute of Biology, São Paulo) described the analysis and interpretation of three 'complement fixation' assays. Finally, several questions on bio-assay, with special reference to the assay of snake venom, were submitted to a panel for discussion.

The first of four papers on medical statistics on July 9, that by Dr. J. O. Irwin (London School of Hygiene and Tropical Medicine), related to an experiment conducted in Singapore with human subjects to assess the influence of air movement, temperature, humidity, clothing and other factors on sweat-rate and other physiological measurements. An interesting application of covariance analysis was shown by Dr. J. N. Manceau (Public Health Service, Pará) in his account of a comparison between two antihelminthics for the control of nematode parasites in seventy-four Belém children. Dr. A. E. Brandt (United States Atomic Energy Commission) described briefly an investigation into the clinical effects of two different very high-voltage sources proposed for the treatment of cancers that are frequently incurable by conventional radiotherapy; he then considered the problems of performing a clinical trial on one type of cancer, with adequate random allocation of patients to the two treatments yet within the limits imposed by medical ethics. The final paper, by Prof. A. Vessereau (Sorbonne), consisted of an interesting application of discriminant function analysis to the diagnosis of medical and surgical cases of jaundice from electrophoretic analysis of serum proteins.

One of the most satisfactory features of the symposium was the lively discussion that followed almost every paper: the variety of questions and comments, and the number of people taking part, proved that the holding of the symposium was fully justified. Moreover, Brazilian science will continue to benefit from this venture, for it provided the impetus for the immediate formation of a Brazilian Region of the Biometric Society (which already has more than fifty members) and also of a Brazilian Genetical Society.

D. J. Finney

# DESIGN OF ELECTRONIC DEVICES FOR PRODUCTION

A SUMMER school on the role of the trained scientist in the design of electronic devices for production was held at the Services Electronics Research Laboratories in Baldock and Harlow during September 20–23. More than sixty university and technical-college professors and lecturers attended. Accommodation was provided by Emmanuel College, Cambridge, and transport to and from the Laboratories was by motor coach.

The first speaker was Mr. A. J. Young (English Electric Valve Co.), who surveyed the recent developments in special valves. He directed attention particularly to one of the functions of management in the device industry, namely, to decide to pursue a particular line of development. The scientific judgment required to execute this function to the best advantage is an increasing need in the industry, and it should be the object of the universities and technical colleges to bring forward scientists having good understanding of their subject and, as a result, good judgment regarding device development. The next speaker was Mr. D. S. G. Lewis (officer in charge of the extension of the Services Electronics Research Laboratory at Harlow), whose subject was magnetrons, and he gave a résumé of the problems facing the designer after fifteen years of development. In particular, he directed attention to the complicated nature of the device, in which the variation of any one parameter alters the effect of every other one. Mr. Lewis sketched the problems arising in the manufacture of magnetrons, giving special attention to the close limits imposed at very high frequencies. The final speaker on the first day was Dr. J. M. Dodds (Metropolitan-Vickers Electrical Co., Ltd.), his subject being high-power klystrons. He explained why the klystron is preferred to the magnetron for certain purposes, and described the design and manufacture of a klystron suitable for driving a very high-power linear accelerator. During this first day examples of modern valves were exhibited, many valve firms contributing samples of their latest designs. In the afternoon, Dr. H. A. H. Boot, one of the inventors of the multi-cavity magnetron, supervised a demonstration of micro-wave valve-making techniques.

The second day of the school opened with a discussion of methods of generation of millimetre waves, given by Mr. P. O. Hawkins (Services Electronics Research Laboratory). Mr. Hawkins, in addition to surveying the field, gave special attention to a floating drift tube klystron capable of delivering 10–20 W. at a wave-length of 8 mm. He was followed by Dr.

R. Q. Twiss (also of the Services Electronics Research Laboratory), who illustrated forward thinking by discussing the prospects of developing and detecting sub-millimetre waves; he gave special attention to the use of electrons travelling at approximately the speed of light. Mr. G. Knott (Mullard Research Laboratories) described the action of travelling-wave amplifiers and of backward-wave oscillators. In the first part of his discourse he referred particularly to the problem of noise in signal amplifiers and to the yet unsolved problems of mechanical design; in the second part he sketched the theory of backward-wave valves and described results achieved at a wave-length of about 2 cm. which may lead to a new generation of low-power micro-wave oscillators.

The school then turned its attention to the important subject of reliability in electronic devices, and on this subject an address was given by Mr. E. G. Rowe (Standard Telephones and Cables, Ltd.). Mr. Rowe explained what steps had been taken since 1945 to improve the general reliability of valves and described the problems which still remained to be solved. He was followed by Mr. G. H. Metson (Research Station of the General Post Office), who dealt specifically with the problem of designing valves for lives of the order of a hundred thousand hours (more than eleven years) and gave a scientific explanation of the factors determining long life in cathodes. In the morning a demonstration was given of millimetre-wave generators, and in the afternoon Mr. P. Gurnell superintended a demonstration of receiving-valve manufacturing techniques. The day closed with a lively discussion of how best to teach at university standard so as to obtain industrial scientists having a real understanding of scientific problems.

On September 22 the school transferred to Harlow, where it was addressed by Dr. D. A. Wright (Research Laboratories of the General Electric Co., Ltd.) and later by Mr. C. P. Lea-Wilson (Harlow) on the subject of thermionic cathodes. Dr. Wright described all types of thermionic emitter, dealing particularly with the limitations of the oxide-coated cathode, while Mr. Lea-Wilson paid special attention to high-temperature sintered cathodes used in magnetrons and high-power klystrons. Mr. J. Pollard (Services Electronics Research Laboratory) then discussed methods of obtaining high vacua and explained that the needs of the valve engineer are not yet adequately met either as regards speed of pumping or as regards ultimate vacua. In the afternoon Mr. J. E. Stanworth (British Thomson-Houston Research Laboratory) described the problems arising in the manufacture of glass and ceramic valve envelopes. In the second part of his address he dealt specifically with some of the new and interesting glasses developed recently. In the evening Mr. A. Monk (Harlow) supervised a demonstration of the use of new materials in valve making.

The final day of the school was devoted to problems arising in connexion with solid-state devices. The introductory discourse was given by Mr. I. M. Ross (Services Electronics Research Laboratory), who surveyed the whole field, giving examples of entirely new solid-state devices which have come to light during the past few years. He was followed by Mr. E. H. Cooke-Yarborough (Atomic Energy Research Establishment), who described the properties of transistors and some of the uses to which they are being put. He emphasized that the transistor is a new type of electronic device in many ways utterly dissimilar to a valve and demonstrated some of the surprising circuits in which transistors can be used. Mr. E. B. Callick (Royal Naval Scientific Service) then discussed the problems encountered in manufacturing transistors and emphasized that these represent an entirely new development in manufacturing methods, where extremely minute traces of impurity are of primary importance and where the physical magnitudes involved are very small indeed. In the afternoon Mr. A. F. H. Thomson (Harlow) described the various types of memory or storage devices which are coming into use, taking the view that magnetic materials will play an ever-increasing part in this field. He was followed by Mr. P. E. Trier (Mullard Research Laboratories), who dealt more specifically with magnetic switching devices. He showed how these can be built up into a full-scale computer and gave special attention to the difficult scientific problems which have yet to be solved in connexion with the use of ferro-magnetic materials and ferrites. During the afternoon a demonstration was given of solid-state devices in use in various ways.

In the short time which remained for discussion it was suggested that the proceedings of the school should be made available, at least in an abridged form, and it is hoped to publish these in the *Journal of Electronics* early next year. J. THOMSON

## ANIMAL MOVEMENT

DURING the British Association meeting at Bristol, Sections D (Zoology) and I (Physiology) held a joint session on September 6, at which the subject of "Animal Movement" was discussed. The first paper was by M. A. Sleigh, speaking on ciliary movement, and in it he gave an account of his own work on the movement of the peristomial cilia of *Stentor*. He suggested that the frequency of beat is a measure of the mechanical activity and that wave velocity is a measure of the metachronal co-ordination. Experiments have shown that the beat frequency and wave velocity have different temperature coefficients. Also it can be demonstrated that changes in the viscosity of the medium and in the viscosity of the protoplasm affect only the frequency and not the wave velocity, while the wave velocity can be substantially altered by digitoxin without appreciably affecting the frequency. The conclusion to be drawn is therefore that the two parts of the system are separate and have very different properties. Mr. Sleigh holds the view that the frequency might be maintained by the first cilium in a row acting as a pace-maker, while the excitation pathway of the wave velocity might be neuroid.

The second paper, by Dr. T. Weis-Fogh, was on the flapping flight of insects, and was illustrated by a slow-motion film on the flight of the desert locust. He described the wing movements in detail, and explained how the film was made and how his co-worker, Dr. Martin Jensen, had used it for estimating the changes both in magnitude and direction of the aerodynamic forces during the beat cycle. It has become clear that the wing cycle can be treated as a series of stationary flow situations and that the torques set up at the wing base can be estimated. When these torques are considered in detail, it is possible to subdivide them into aerodynamic and inertial torques, and to relate them to the torque-producing components within the body. From this lysis, it is evident that the inertial torques are most balanced by elastic torques arising from ormations of the body cuticle. When the various ques are summed for different phases of the beat, result equals the torque which the flight muscles st produce. It appears that some two-thirds of work is being expended against aerodynamic ces, and that the mechanical efficiency of the scle system is 17–18 per cent.

The third speaker, Dr. R. H. J. Brown, discussed flapping flight of birds. He pointed out that re are several different types of flapping movements, and that these are found either in different ds or in the same bird in different situations. The ious types of flapping cycle were illustrated by tern slides, and the functional differences between various phases were described. It is clear that reas the down-strokes are almost the same for birds, the up-strokes may be entirely different h in path and function. These various types of -stroke are found, with few exceptions, to be ated to the size of the bird. The small birds up the size of a pigeon usually fold their wings irely during the up-stroke in slow flight. The eon and birds of similar size use a propulsive -stroke in slow flight and a passive one in fast ht; and in the large species the up-stroke is sive except perhaps just before landing. Individual ht habit makes the transition point from one type the other indefinite. It can be shown that these ferences are to be expected from considerations of scle weight, wing area and wing mass (inertia). ile the qualitative picture is fairly clear, there is le information from which any quantitative imates of aerodynamic or overall efficiency can be de.

The last paper was given by Dr. O. C. J. Lippold, o considered fatigue in human voluntary muscle. suggested that the fatigue may be attributable one or more of four factors: first, the voluntary ve may be diminished; secondly, the nerve conction may be impaired; thirdly, the neuroscular junction may be fatigued; and finally, the ntractile mechanism may itself become weaker. It probable that three of these factors are responsible the diminished activity in fatigue, and that the in effect is due to one or other in different cirnstances. For example, prolonged work, not of a enuous nature, undoubtedly gives rise to central igue; but if a strong enough motive arises, the scle activity can be restored to the unfatigued el. To what extent the occurrence of a neuroscular block is important has not been settled, hough experiments described by Dr. Lippold lead n to believe that such fatigue does not occur. He o holds the view that fatigue of the neural pathy is not a factor. On the other hand, under conions of strenuous exercise it is clear that the igue can be predominantly muscular, and that the set of fatigue is accelerated and the recovery layed by impairment of the blood supply to the scle. Finally, Dr. Lippold suggested methods by ich the blood supply to the muscle might be reased, and thus postpone the onset of fatigue.

During the short discussion which followed, Mr. igh was questioned on his suggestion of a neuroid ntrol in ciliary movement and pointed to the uctures associated with cilia as supporting his ws, and then Dr. Weis-Fogh explained some of his imates of internal work and power losses in locust ht.

# STANDARDS IN BRITISH INDUSTRY

IN two recent broadsheets (Nos. 381 and 382, July 11, 1955) Political and Economic Planning reviews the various types of standards in use in British industry, examines the arguments for and against their use and scrutinizes the work of the British Standards Institution; in particular, the method of preparing standards and the extent to which they are adopted are considered, and whether the Institution, as at present constituted, is capable of doing justice to its growing responsibilities at home and overseas.

Industrial standards fall into two broad categories: functional standards, or the tools used in doing a job; and dimensional standards which, by laying down dimensions and tolerances for finished and semi-finished goods, secure interchangeability and simplification. Frequently there are combinations of both types. Britain's leadership in aircraft design has been helped considerably by the many standards relating to production, drawing-office practice and engineering construction, and objections to the use of standards in industry are often based on misconceptions of what standards imply. The first of these two broadsheets indicates the vital contribution which standardization can make to efficiency in industry by cutting out waste of machine-time, materials, power and labour, and also the importance of standards in foreign markets. Many problems are involved in the formulation of standards both technically sound and commercially practicable, and the resolution of these difficulties in Great Britain falls to the British Standards Institution, which is the subject of the second broadsheet.

Essentially the British Standards Institution is a co-ordinating body bringing together the technical knowledge of those engaged in industry, professional associations, technical colleges, universities and government departments, and the practical and commercial knowledge of producers, distributors and consumers in an endeavour to produce standards acceptable to all interests concerned. Until 1931, its activities were mainly confined to the engineering industry; but in that year a Supplemental Royal Charter enlarged its terms of reference to user industry as a whole and its name was changed from British Engineering Standards Association to British Standards Institution. By 1939 it had grown to something like its present size and published nearly a thousand standards for a wide range of engineering and chemical, building and like materials. It has always worked for the promotion of British standards abroad, and continues to take an active part in the movement for internationally accepted standards. Between the two World Wars it became concerned with the standards since known as Codes of Practice, of which more than a hundred and fifty have been issued, ranging from the planning of buildings for ensuring adequate sunlight to the use of electronic valves.

The broadsheet suggests that the Institution could take a wider view of the whole question of standards, and that its work at home should follow some order of priority more closely related to the productive efficiency of the country as a whole. Closer co-operation between the Institution and the British Productivity Council in an effort to introduce standards, where they are likely to be of most benefit, is suggested; and with the growing adoption of standards overseas, the Institution must turn its attention increasingly to securing international agreement, aligning British standards to the requirements of overseas customers, and promoting British Standards in other countries. Some expansion of the publicity and information services of the Institution is desirable, and surveys are suggested which could indicate an order of priorities by showing where its work is most and least effective, particularly with regard to the smaller firm. The need for solid financial basis is emphasized. The governm contribution for 1955–56 should be of the order £120,000; but the present arrangements termin after 1956–57, and it is pointed out that it is import that the Institution's income must be assured fo sufficient period ahead to allow it to plan w confidence, possibly by means of a quinquenn government grant and equivalent longer-term s scriptions from industry.

# THE POLYPEPTIDE CHAIN CONFIGURATION OF COLLAGEN

By Drs. PAULINE M. COWAN, STEWART McGAVIN and A. C. T. NORTH*

Wheatstone Physics Laboratory, King's College, London, W.C.2

THE complete determination of the structure of collagen presents two major problems: first, that of discovering the configuration of the individual polypeptide chains by the application of X-ray diffraction data; second, the understanding and significance of the larger-scale structure seen in the electron microscope. We reserve a discussion of the larger structure and its relation to that of the individual chains for a later communication. This communication deals with the polypeptide configuration and is an elaboration of earlier remarks[1,2] on the relationship between the structures of poly-L-proline and of collagen.

A consideration, in fact, of the recent work on this synthetic polymer[1,2] and on collagen itself[3-4] has clarified the principles on which the structure of collagen must be based, and shows that an approximate solution can now be arrived at with reasonable certainty. The determination of the exact atomic positions within a single chain will require a much closer study and may ultimately rest on the possibility of an improvement in the experimental data.

The main features of the collagen polypeptide chain configuration are, we think, indicated by the joint consideration of the following: (1) the high-angle X-ray diffraction pattern; (2) the amino-acid composition and sequence analysis; (3) the structure of poly-L-proline.

The configuration must also account for physical properties such as density and infra-red absorption.

## High-Angle X-Ray Diffraction Pattern

The general features of the high-angle X-ray pattern are consistent with a system of hexagonally packed rods, 12 A. apart in dry material, the separation increasing with hydration. Each rod contains a set of atoms, which may be one or more amino-acid residues, repeated at axial intervals of 2·86 A. in the unstretched material. On stretching the fibre the axial repeat increases to 3·1 A. or more, and the improved X-ray pattern suggests that the atom sets are repeated on a helical structure. From the X-ray spacings, the dimensions of possible alternative helical systems can be derived[3-4]. Theoretically, a very large number of helical systems can be devised which fit the observed high-angle X-ray diagram, but it seemed to us that the actual model would be one of a comparatively small number of simple alternatives[3-4], namely: (*a*) a single helix with a period of 28·6 A., containing either three or sev turns and ten atom sets; (*b*) two concentric helic related by a diad axis, each helix repeating exact after 57·2 A. with three or seven turns and twen atom sets; (*c*) three concentric helices related by triad axis, each helix repeating exactly every 85·8 Each chain would contain thirty atom sets and thr or seven turns in its repeat. For three turns, sin the atom sets and turns are both multiples of there would be a complete repeat after 28·6 A.

Examination of the general form of the intensi distribution to be expected from such systems[5], and comparison with the observed high-angle X-r pattern shows that, in collagen, the single helic form (*a*) is the most likely, as illustrated in Fig. In the following discussion, this form is assumed be correct.

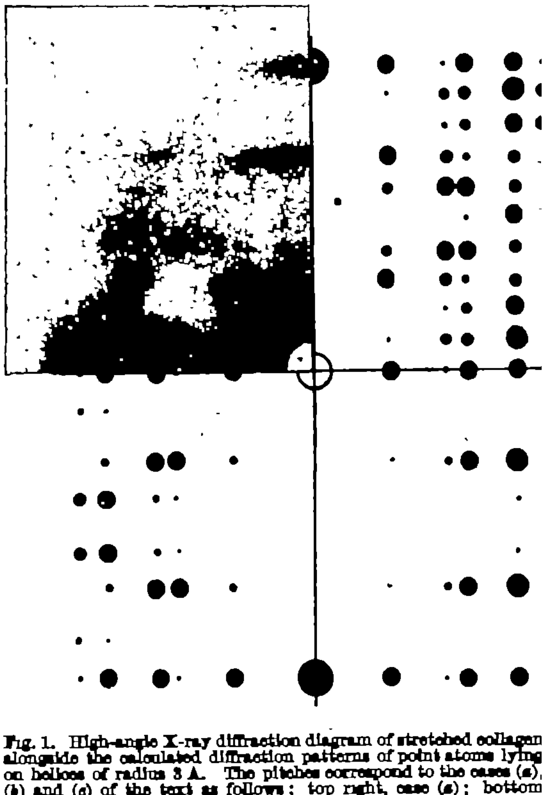

Fig. 1. High-angle X-ray diffraction diagram of stretched collagen alongside the calculated diffraction patterns of point atoms lying on helices of radius 3 A. The pitches correspond to the cases (*a*), (*b*) and (*c*) of the text as follows: top right, case (*a*); bottom left, case (*b*); bottom right, case (*c*)

---

* Now at the Davy Faraday Research Laboratory, The Royal Institution, 21 Albemarle Street, London, W.1.

The measured density of dry collagen fibres shows at there are probably three amino-acid residues in e 2·86 A. atom set. The single-helix form (*a*) could en itself arise in one of several probable alternative ays: (i) a single polypeptide chain with three sidues in 2·86 A.; (ii) a unit of three similar arallel chains, each with one residue in 2·86 A.; i) a unit of three chains, each with one residue in 86 A., so related that the complete system is ecified by a single helical array of the dimensions (*a*).

We have investigated a large number of structures type (i), but have found none to be satisfactory. he difficulties of joining straight non-integral lices, as in (ii), by an adequate number of hydrogen nds, have already been pointed out[2–4]. It is possible at these difficulties may be overcome if, instead of system of three straight helices, we have a comound system of coiled coils, corresponding to case (iii). The intensity distribution given by a compound elical system involving several single helices wound lically around one another is, as pointed out by rick[10], more complex than for the simple cases, and is not easy to formulate by inspection all the mbinations of minor and major helix pitches which ould produce a given intensity distribution. A articular case, however, is suggested by the poly-L-roline and collagen data. In this, three chains, each ith three residues per turn relative to the major elix, slowly coil around each other so that the umber of residues per turn, relative to the common xis, becomes 3⅓. Such a system may be shown to orrespond to case (iii), and is, therefore, of a form onsidered favourable from the analysis of the X-ray iagram. Further, the number of residues per turn each chain relative to the other chains in the unit integral, so that a regular form of hydrogen bonding feasible.

Of the models proposed for the structure of colagen, only three[11–13] put forward since the helical nalysis of the X-ray diagram was first described[6,7] ave the required basic dimensions. The first two of hese involve *cis* residues, which seems very unlikely view of the infra-red spectrum of collagen[14,15] and f the structures of other peptides, particularly poly-proline; the third, that of Ramachandran and artha[13], is discussed below.

## Amino-Acid Composition and Sequence Analysis

Although the complete amino-acid sequence in llagen has not yet been determined, some sequence udies have been made[16,17] and we can reach certain ntative conclusions. Examination of the small eptides which have been identified suggests that, if ere is a repeated short sequence, it is not a rigid ne (or is not maintained throughout the protein aterial), but is rather of the form —$R_1$—$R_2$—$R_3$—, here $R_1$ may be proline, $R_2$ may be hydroxyproline, nd $R_3$ is, probably, nearly always glycine. The most teresting result is the isolation of the peptides glycyl rolyl hydroxyprolyl glycine and glycyl prolyl ydroxyproline. All three residues occur in sequences ther than the above, with the exception that hydroxyroline always appears to be followed by glycine. lthough glycine is about one-third of the total umber of residues, proline is only one-eighth and ydroxyproline one-tenth in bovine collagen[18], so that most the sequence —prolyl—hydroxyprolyl—lycyl— could only account for about one-third of e total structure. While glycine, the other non-polar residue, and the polar residues each account for about one-third of the total, the evidence does not suggest a rigid (—non-polar—polar—glycine—) sequence.

It may be that the sequence —prolyl—hydroxyprolyl—glycyl—, or a similar sequence, is largely concentrated in one of the three chains of a structure such as that discussed above, so conferring on this chain a special configuration. The other two chains can be pictured as crystallizing about this one. In any event, it is probable that a high proportion of these residues inserted into the α-helix[19] or β-pleated sheet[20] would make these structures unstable as a result of distortion and the reduced number of possible hydrogen bonds, and that a distinct type of chain might be the most stable. In the limit, a structure consisting entirely of proline residues might be expected to take up such a new configuration; this was in fact found to be the case.

## Structure of Poly-L-Proline

An X-ray study of poly-L-proline[1,2], synthesized recently by Berger, Kurtz and Katchalski[21], shows the polymer to have a helical structure in which the amino-acid residues are related by an exact threefold screw axis. The residue repeat along this axis is 3·12 A., and the similarity of this spacing to that of stretched collagen suggests strongly that the two chains have very similar configurations.

Poly-L-proline, like collagen, has a high specific *lævo* optical rotation[21]. It has been suggested that this rotation in collagen is due to the special type of helical configuration[22]. A left-handed sense is imposed sterically on the poly-L-proline chain, and it seems highly probable that the minor helices of a three-chain collagen structure would also be left-handed.

We now wish to consider ways in which three poly-L-proline type chains may be bonded together to form this compound system. The work described below was briefly referred to at the Third International Congress of Biochemistry, Brussels, 1955.

If one in three of the residues of the threefold chain has a secondary amide-group, then three chains can be imagined to be joined together by hydrogen bonds in two simple ways corresponding to the two trigonal positions in the poly-L-proline structure. In either system the individual left-handed chains are themselves related by a threefold left-handed screw. Looking in the —αC—NH—CO—αC— direction of the chains and taking the NH . . . O direction as the direction of hydrogen bonds, then the latter are alternately pointing clockwise or anti-clockwise. When the side-chain interactions are taken into consideration, the following results emerge. In the anti-clockwise system there are a number of short van der Waals contacts which would force the chains to take up a non-integral screw configuration. If a second proline ring is replaced by any side-chain, *R*, in the sequence —glycyl—*R*—prolyl—, there is a single short contact, which would cause distortion, whereas if two residues in three are glycine, there are no short contacts. In all cases the system might be stabilized with a three-and-a-third-fold screw-axis by additional hydrogen bonds. In the clockwise system, there do not appear to be any seriously short contacts, nor can such additional hydrogen bonds be readily made, and, although a three-and-a-third-fold structure can be built, there seems little reason for the chains to depart from the exact three-fold configuration. A preliminary investigation suggests that in the anti-clockwise arrangement there may be two simple ways of making these extra hydrogen bonds: first, by replacement of a second proline in the three-residue sequence by another secondary amide residue, so that by slight distortion of the chains a second set of NH . . . O hydrogen bonds can be formed between peptide backbones; or second, by using the polar groups of side chains. One of the remaining proline residues could be replaced by hydroxyproline or by other hydroxy, acidic or basic residues, which might allow formation of an OH . . . O or NH . . . O bridge to an unbonded carbonyl group. The work of Gustavson[23], which shows a correlation between thermal stability and hydroxyproline content of various collagens, is in favour of an O—H . . . O hydrogen bond, in the case of hydroxyproline at least, although there does not at the moment appear to be any correlation with the proportion of other polar residues.

While this work was in progress, we became aware that very similar lines of thought were being pursued by other workers in the field. Ramachandran and Kartha[13] have been the first to propose a structure, having the superhelical configuration described above, in which the basic NH . . . O bonding is in an anti-clockwise direction with the structure additionally stabilized in the first of the ways mentioned above. A rigid —prolyl—glycyl—*R*— sequence is required, so that the structure as it stands cannot accommodate a number of known sequences, particularly —prolyl—hydroxyprolyl—. The hydrogen-bond angles are rather greater than is normally considered permissible, although this may be consistent with the abnormally high NH-stretching frequency. The optical transform of this model, however, is in good general agreement with the observed diffraction data; while not correct in every detail, this strongly suggests that the general form of the backbone configuration is correct.

In conclusion, it seems to us highly probable that the collagen structure consists of three chains of the poly-L-proline type modified to give 3⅓ residues per turn. These three chains are bound together by a system of NH . . . O hydrogen bonds between residues approximately on the same axial level, and the structure is further stabilized and the 3⅓ residues per turn maintained by additional hydrogen bonding. It would seem that X-ray methods alone may not provide sufficient data to distinguish between differe structures of this general type, and it is possible th the actual structure might be a complex of slight different arrangements resulting in the maximu possible stability.

We are grateful to Prof. J. T. Randall for l continued advice and encouragement throughout tl course of this research. Two of us (P. M. C. and McG.) are indebted to the Nuffield Foundation f research fellowships during the tenure of which th work was carried out. [Nov. 9

*Note added in proof.* Since this paper was su mitted for publication a communication has appear by Rich and Crick[24], in which they propose tw alternative structures for collagen of the kind di cussed above. They have called these collagen I an II. Each has a single system of NH . . . O hydroge bonds, respectively in the anti-clockwise and clock wise arrangements.

# QUANTITATIVE SEPARATION OF B VITAMINS BY ELECTROPHORESIS ON AGAR PLATES

By Dr. G. MARTEN*

Anstalt für Vitaminforschung und Vitaminprüfung, Potsdam-Rehbrücke

We have already described the determination of components of a mixture of vitamin derivatives after chromatographic separation on circular paper[1]. This method makes a fairly exact estimation possible, but is not sufficiently sensitive for direct use with some biological material, owing to the limited quantity of material that can be placed on the paper. The lower limit of sensitivity of 0·05 μgm. for thiamine and 0·15 μgm. for nicotinic acid and derivatives requires a certain minimum concentration of these substances. The assay is, moreover, complicated by the difficulty of estimating microbiologically active derivatives not clearly separable by chromatography Siliprandi and his collaborators[2] have applied electro phoresis on paper to the separation of derivatives c thiamine, riboflavin, pyridoxin and nicotinic aci which they later measured chemically. The sensitivit of their procedure (approximately 10 μgm.) can b greatly increased if electrophoresis is combined wit a microbiological assay by applying the dried pape to a suitable medium. It is nevertheless limited b the fact that only about 10 mm.$^3$ of the solution ca be applied to the paper.

We have developed a more suitable method b carrying out electrophoresis directly in thin layers c agar jelly as used in macro-electrophoresis[4]. Washe

ilms of silica gel or polyvinyl alcohol have been ised; possibly other transparent jellies could be ised, but agar is to be preferred as a medium as it an be easily handled. High-voltage electrophoresis up to 10,000 V.) is carried out in silicon films. After eparation in the electric field, another layer of agar elly is placed on the first. This second layer contitutes a medium containing all the substances equired by the test organisms seeded into the agar xcept that to be determined. Zones of growth ppear in those spots corresponding to the presence f the vitamin or its active derivative in the lower ayer of the agar jelly. As in all diffusion tests, the ogarithm of the dose is directly proportional to the liameter of the growth zone.

The vitamins can also be demonstrated by chemical eaction in the agar in the same way as on paper see middle part of Fig. 2). Quantitative chemical letermination is possible after cutting out and iquefying the appropriate portions of the agar jelly. For the separation of the thiamine roup (shown in Fig. 2) the lower ayer of agar should have a pH of ·3. The warm, fluid agar is thereore diluted with phosphate buffer o a final concentration of 0·05 *M*. The most suitable concentration of gar must be determined for each ystem, and in general varies beween 1 and 2 per cent. We use lass plates up to 60 cm. × 80 cm. ramed by glass strips (2 cm. in readth) which are caulked with gar to hold the liquid agar film on he previously warmed plate (Fig. 1, 8). Without appreciable warmng of the agar film, 1–3 mm. thick, a current of 100–150 m.amp. can be put through it at a potential lrop of 7 V./cm. Distilled water an be sprayed on the film should it lry up with prolonged use. Under hese conditions the separation of hiamine and its derivatives is chieved in about four hours and an be controlled by the use of visible indicators such as acid uchsin, methyl green or riboflavin. The test substances are placed in oles, 5–10 mm. in diameter, punched in the jelly with a cork borer along a starting line at intervals of 2–4 cm. (Fig. 1, 2). If necessary, another layer of agar may be added along the starting line to increase the thickness. In this way 0·2 ml. or more of substrate can be placed on the agar, the grading of the doses being preferably logarithmic. Glass cups or filter-paper disks can be used instead of the punched holes for accommodating the substrate. Even solid substances such as minced organs, fæces and also blood can be placed directly on the agar, after denaturation of protein, without previous extraction.

In certain instances, increased separation of the active growth factors can be achieved by a combination of paper chromatography and electrophoresis in agar jelly, strips of the chromatogram being placed either singly or packed along the starting line. A frame 3 cm. in diameter composed of glass strips which are fixed by clamps is set on the solid agar plate and filled with liquid agar to a height of about 5 mm. and serves as an electrode vessel (Fig. 1, 3). With narrow electrophoretic plates up to 10 cm. wide, two sintered glass filters (Eintauchnutsche Schott *G4*) can be used for the purpose with two carbon rods inserted to serve as electrodes. If the pores in the sintered glass filters are too big, they can be covered with agar. The apparatus includes a heating and cooling device and a pumping system for the electrolyte solution. Before the agar is poured on the glass plate, the plate is warmed by pumping water at 55° C. into a chamber formed by two glass plates and a soft rubber gasket (Fig. 1, 6). For cooling, cold water is passed through the chamber (Fig. 1, 7). Incubation of the test organisms is carried out overnight after the requisite adjustment of temperature in the thermostat (Wobser Ultrathermostat) (Fig. 1, 5). During long runs, the electrolyte solution is repeatedly transferred by a blower from the anode to the cathode vessel and vice versa (Fig. 1, 4) to keep the hydrogen-ion concentration around the electrodes reasonably constant.

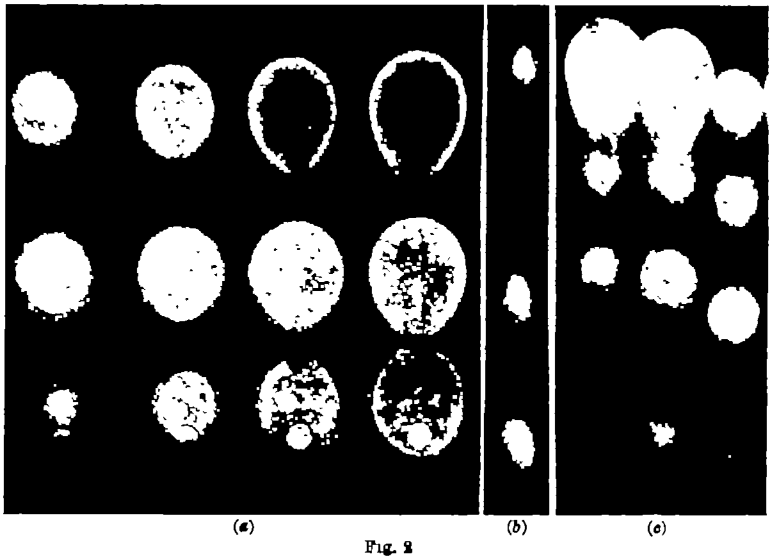

Fig. 2

(*a*) Growth zones with *Lactobacillus fermentum*. Standard mixture, 0 008–0 064 μgm Bottom row, pyrophosphoric acid ester of thiamine; middle row, monophosphoric acid ester of thiamine Top row, thiamine itself

(*b*) Chemical development to thiochrome (in ultra-violet light)

(*c*) Left: urine after a loading-test with thiamine. Centre: the same urine, but with added standard mixture of thiamine pyro- and mono-phosphoric acid ester, thiamine disulphide and thiamine. Right: the standard mixture alone

The growth zones shown in Fig. 2 were obtained with *Lactobacillus fermentum* ATCC 9338, by means of which as little as 0·002 μgm. of thiamine can be demonstrated. The diameter of growth zones is directly proportional to the logarithm of the dose within the limits 0·008–0·512 μgm. of thiamine (see Fig. 2). The pyrophosphoric acid and the monophosphoric acid esters of thiamine, thiamine itself and its disulphides and disulphide phosphates migrate to the cathode. For this reason the starting point for the thiamine group is placed near the anode. The speed of migration is in certain circumstances influenced by the ions present in the test solution. If necessary, the growth zones are identified by the use of an internal standard (see Fig. 2). We were able to demonstrate by such means the presence of thiamine disulphide in all the organs and excreta examined.

It is preferable to use for these tests organisms responding to as many factors as possible rather than the organisms of high specificity used for microbiological tests. It is by the different requirements of different organisms that a new factor can b identified and its chemical constitution inferred. Fo example, *Lactobacillus fermentum* requires the intac thiamine molecule, whereas *Rhodotorula mucilaginosa* is satisfied with the pyrimidine component alone *Phycomyces blakesleeanus* responds to higher concentrations of the thiazole moiety but not to pyrimidine. However, in the presence of small quantitie of thiazole, the mould develops a mycelium on those spots containing pyrimidine, or conversely forms i with small amounts (4 mgm./100 ml. medium) o pyrimidine on spots containing thiazole.

A detailed account of this work will be publishe elsewhere[4]. [June 14

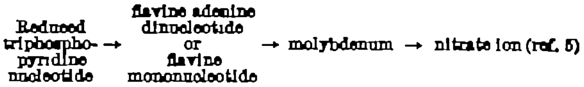
# VALENCY CHANGES OF MOLYBDENUM DURING THE ENZYMATIC REDUCTION OF NITRATE IN *NEUROSPORA*

By Dr. D. J. D. NICHOLAS and Dr. H. M. STEVENS

A.R.C. Unit of Plant Nutrition (Micronutrients), Long Ashton Research Station, University of Bristol

MOLYBDENUM has been identified as a constituent of nitrate reductase in *Neurospora crassa*[1,2], *E. coli*[3] and in higher plants[4]. The micronutrient undergoes oxidation-reduction changes during nitrate reductase action in the following sequence:



Reduced triphosphopyridine nucleotide → flavine adenine dinucleotide or flavine mononucleotide → molybdenum → nitrate ion (ref. 5)

This communication reports that, during the enzymatic reduction of nitrate, the valence change undergone by molybdenum involves $\text{Mo}^{6+}$ and $\text{Mo}^{5+}$. Paper chromatography was used to prepare pure solutions of salts with molybdenum in various valency states, and for identifying $\text{Mo}^{3+}$, $\text{Mo}^{5+}$ and $\text{Mo}^{6+}$. Sodium molybdate reduced with sodium dithionite, which acts as an electron donor for the enzymatic reduction of nitrate, was shown to contain $\text{Mo}^{5+}$ as the most reduced valence state of the micronutrient. Further, $\text{Mo}^{5+}$ prepared free from molybdenum in the other valence states acts as an effective donor for nitrate reductase action, but $\text{Mo}^{3+}$ is without effect. $\text{Mo}^{3+}$ will reduce nitrate non-enzymatically.

## Determination of Valence States of Molybdenum present in Dithionite-reduced Sodium Molybdate

*$\text{Mo}^{6+}$ and $\text{Mo}^{5+}$.* The molybdate solution reduced with sodium dithionite was spotted on acid-washed Whatman No. 1 paper, and run in the following solvent mixture: water 100, glacial acetic acid 10, potassium thiocyanate 10 gm. The chromatograms were dried and developed in one of three ways: (*a*) spraying with 0·2 per cent dithiol in 2 *N* hydrochloric acid; (*b*) spraying with a mixture of 10 per cent stannous chloride and 10 per cent potassium thiocyanate; (*c*) exposure to hydrogen chloride vapour.

$R_F$ values (which had been checked with standard solutions of molybdenum of the two valencies) are: $\text{Mo}^{6+}$ 0·3–0·4; $\text{Mo}^{5+}$ 0·8.

An alternative method is the addition of 8-hydroxyquinoline in 50 per cent chloroform–ethanol to the dithionite-reduced molybdate solution. The chloroform layer containing the oxinates was spotted on Whatman No. 1 paper, dried and run in ethyl alcohol. The oxinate spots of $\text{Mo}^{6+}$ and $\text{Mo}^{5+}$ were observed in daylight or in ultra-violet light:

$\text{Mo}^{6+}$ oxinate (yellow), $R_F = 0$, maxima 250, 370 mμ; minimum 280 mμ.

$\text{Mo}^{5+}$ oxinate (reddish purple), $R_F$ 0·9, maxima 243, 540 mμ; minimum 480 mμ.

These values had been determined using standard solutions of the molybdenum of the two valencies.

*$\text{Mo}^{5+}$ and $\text{Mo}^{3+}$.* The dithionite-reduced solution of molybdate in hydrochloric acid was separated on paper using an ether–thiocyanic acid solvent prepared by adding 10*N* hydrochloric acid (40 ml.) to a solution of potassium thiocyanate (40 gm. in 40 ml. water) (the mixture was cooled to 15° and extracted with 150 ml. redistilled ether; the ethereal layer was filtered, and stored in a refrigerator). After drying, the paper was sprayed with 10-vol. hydrogen peroxide, then dried and sprayed again with a mixture of 10 per cent potassium thiocyanate and 10 per cent stannous chloride. No molybdenum valency less than 5 was detected in the reduced molybdate solution. Using standard solutions of $\text{Mo}^{5+}$ and $\text{Mo}^{3+}$, $R_F$ values in this solvent are 0·8 and 0·0, respectively.

$\text{Mo}^{3+}$ is readily oxidized to $\text{Mo}^{5+}$ in the presence of $\text{Mo}^{6+}$, so that the separation of $\text{Mo}^{3+}$ in the presence of $\text{Mo}^{6+}$ was not feasible. It has not been ssible to prepare and determine Mo$^{4+}$ in solution cause of its instability.

## eparation and Determination of Mo$^{6+}$, Mo$^{5+}$ and Mo$^{3+}$

Mo$^{6+}$ was prepared by acidifying sodium molybdate th $2N$ hydrochloric acid, and Mo$^{5+}$ by dissolved olybdenum pentachloride in acetone. A chloride lution of Mo$^{3+}$ was made by reducing a mixed lution of sodium molybdate (0·5 gm./5 ml. water) d $10N$ hydrochloric acid (10 ml.) with zinc dust til the solution ceased to give a red colour when iquots were tested with 10 per cent potassium thioanate. The valency state of molybdenum in such mixture was checked by reducing 1 ml. of a sodium olybdate solution containing 12·5 mgm. molybmum per ml. as described. When all the zinc had ssolved, the solution was diluted with water to 0 ml.; 40–50 ml. aliquots were mixed with 50 ml. V sulphuric-acid and titrated with standard tassium permanganate.

Exp. 1. 5,625 μgm. of reduced molybdenum quired 3·5 ml. 0·05$N$ potassium permanganate. lculated for Mo$^{3+}$ → Mo$^{6+}$ + 3e, 3·51 ml.; for o$^{4+}$ → Mo$^{6+}$ + 2e, 2·34 ml.

Exp. 2. 5,000 μgm. of reduced molybdenum quired 15·6 ml. 0·01$N$ potassium permanganate. lculated for Mo$^{3+}$ → Mo$^{6+}$ + 3e, 15·62 ml.; for o$^{4+}$ → Mo$^{6+}$ + 2e, 10·4 ml.

The zinc and traces of Mo$^{5+}$ were removed from e solution as follows: 5 ml. of the mixture was aced on a cellulose column (15 cm. × 1·5 cm. ternal diameter). When the solution had soaked , the inner glass wall above the cellulose was wiped ith filter paper to remove any adhering liquid. The lumn was then eluted with thiocyanic acid in her, and this was continued for at least 15 min. ter the red band of Mo$^{5+}$ CNS had passed through e column. Ether was then passed through the lumn to remove thiocyanic acid, followed by dislled water to elute Mo$^{3+}$. The final eluate was armed to 45° and carbon dioxide passed through expel ether. The Mo$^{3+}$ solution was diluted to 0 ml. with water and stored in the refrigerator.

The molybdenum concentrations in the solutions ere determined as follows:

*Mo$^{6+}$*. To 5 ml. of sodium molybdate solution ntaining 2·5 mgm. molybdenum were added 5 gm. tassium thiocyanate and 10 ml. $5N$ hydrochloric id; the mixture was kept at 50° for 15 min. and as diluted to 100 ml. with 10 per cent potassium thioanate in $2N$ hydrochloric acid. The solution was tered through a No. 42 Whatman paper, and –20 ml. aliquots were extracted with 40–50 ml. distilled ethyl acetate. The ethyl acetate extracts ere measured at 490 mμ on a Spekker absorptioeter (blue-green filters). The concentration range ed was 1–12 μgm. molybdenum per ml. ethyl acetate.

*Mo$^{5+}$*. To 1 ml. of molybdenum pentachloride in etone containing approximately 500 μgm. molybmum per ml. was added 10 ml. of 10 per cent tassium thiocyanate in $2N$ hydrochloric acid and e solution kept at 50° for 15 min. to reduce any o$^{6+}$ to Mo$^{5+}$. Aliquots were extracted with 40–50 ml. hyl acetate and determined as described previously.

*Mo$^{3+}$*. To 0·5 ml. of Mo$^{3+}$ solution containing proximately 500 μgm. molybdenum per ml. was ded 10 ml. of 10 per cent potassium thiocyanate $2N$ hydrochloric acid followed by 10-vol. hydrogen roxide until the red colour produced started to fade. Then 10 per cent stannous chloride in $2N$ hydrochloric acid was added until the restored red colour no longer deepened. The mixture was then shaken with 40–50 ml. of ethyl acetate; the ester layer was filtered, and the colour measured at 490 mμ.

Table 1. Mo$^{5+}$ AS AN ELECTRON DONOR FOR THE ENZYMATIC REDUCTION OF NITRATE

Millimicromoles of nitrite formed in the reaction mixture

| Exp. | Reduced triphos. pyr. nucleotide Enzyme Flavin mono-nucleotide Pot nitrate | Mo$^{5+}$ Enzyme Pot. nitrate | Mo$^{5+}$ Pot. nitrate | Mo$^{5+}$ Boiled enzyme Pot. nitrate | Mo$^{6+}$ Enzyme Pot. nitrate |
|---|---|---|---|---|---|
| 1 | 35 5 | 36 | 0 | 2 | 0 |
| 2 | 24 | 22 | 0 | 1 | 0 |

0·5 ml. of enzyme containing approximately 400 μgm. of protein, 0·20 ml. reduced triphosphopyridine nucleotide (2 μmol./ml.), 0 20 ml. flavin mononucleotide (0 09 μmol. per ml.), 0·6 ml. 0·1 $M$ potassium nitrate and 50 μgm. Mo$^{5+}$ or Mo$^{6+}$ contained in 0 01 ml., each checked for purity by paper chromatography. The reaction mixtures were made to 2 ml. with 0·1 $M$ phosphate buffer $p$H 7 5. After 10 min. at room temperature the mixtures were assayed for nitrite using sulphanilamide and N-(1-naphthyl) ethylenediamine reagents.

## Enzymatic Reduction of Nitrate by Nitrate Reductase

Nitrate reductase was prepared from *Neurospora crassa* (Wild type 146, microconidial; kindly supplied by Dr. William D. McElroy, Johns Hopkins University, Baltimore) as described elsewhere[5]. Mo$^{5+}$ and Mo$^{6+}$ solutions, the valency purity of which was previously checked by paper chromatography, were tried as electron donors in the presence of the purified enzyme. The results are given in Table 1.

The results in Table 1 show that Mo$^{5+}$ is as effective as reduced triphosphopyridine nucleotide as an electron donor for the enzymatic reduction of nitrate. Mo$^{6+}$, however, is without effect. In the absence of nitrate reductase or in the presence of the boiled enzyme, Mo$^{5+}$ does not reduce nitrate. The very small amount of nitrite formed with the boiled enzyme is attributed to a release of bound nitrite from the denatured protein.

## Non-enzymatic Reduction of Nitrate by Mo$^{3+}$

Mo$^{3+}$ reduces nitrate non-enzymatically, whereas Mo$^{5+}$ or Mo$^{6+}$ is without effect. Thus it is possible to determine Mo$^{3+}$ in the presence of Mo$^{5+}$ by measuring reduction of nitrate. The rate of chemical reduction of nitrate by Mo$^{3+}$ is approximately twice that of nitrate reductase action. Over the range 0·1–20 mμ $M$ nitrate, 2 mμ $M$ Mo$^{3+}$ will reduce 1 mμ $M$ nitrate chemically.

It is unlikely that the chemical reduction of nitrate by Mo$^{3+}$ is important for the reduction of nitrate in *Neurospora*, because Mo$^{3+}$ has not been detected in the felts and the enzymatic reduction involves Mo$^{5+}$ and Mo$^{6+}$ only.

It has not been possible to effect a non-enzymatic reduction of either Mo$^{6+}$ to Mo$^{5+}$, or Mo$^{5+}$ to Mo$^{3+}$, using reduced di- or tri-phosphopyridine nucleotide as an electron donor. Reduced triphosphopyridine nucleotide does not appear to reduce Mo$^{5+}$ to Mo$^{3+}$ in the presence of nitrate reductase. [July 8

## Function of Krause's Membrane

A. V. Hill[1] has shown that ordinary diffusion of a chemical substance is too slow to explain the rapidity with which the contraction in the interior of a striated muscle fibre is set off by the action potential, which is a change in the potential difference across the surface membrane; some more rapid link must therefore exist. Krause's membrane (*Z* line, telophragma) is a possible anatomical basis for such a link[2], since it extends continuously across the fibre and is attached to the interior of the sarcolemma[3,4].

We have tested this possibility by depolarizing very small areas of the surface of fresh fibres isolated from frog muscles. A micropipette with a squared-off tip, diameter about 2 microns, filled with isotonic sodium chloride, was firmly applied to the fibre surface and fed with pulses of current of $\frac{1}{4}$-sec. duration, making the interior of the tip about 20–40 mV. negative with respect to the Ringer bath. Fig. 1 shows that, when this was done opposite an *A* band, there was no contraction, while if the pipette was opposite an *I* band (with *Z* at its centre), that *I* band alone shortened, the contraction spreading only a short way in. In neither case was it possible to initiate shortening with pulses which hyperpolarized the membrane. Greater inward spread was obtained with a 4-micron pipette (Fig. 2), which is the largest that could be used without overlapping more than one *Z* line. The *I* band to which this pipette was applied now shortened for a distance of about 10 microns inward from the surface, while neighbouring *I* bands (1·5–3 microns from the central *Z* line) did not shorten and were, in fact, passively stretched.

The fibres had ceased to give propagated electrical activity by the time we made these observations, but were still capable of powerful local twitches in response to depolarization of a larger area membrane. The current applied with the micr pipette would not be expected to set up a propagate action potential even in an excitable fibre, becaus of the smallness of the area depolarized.

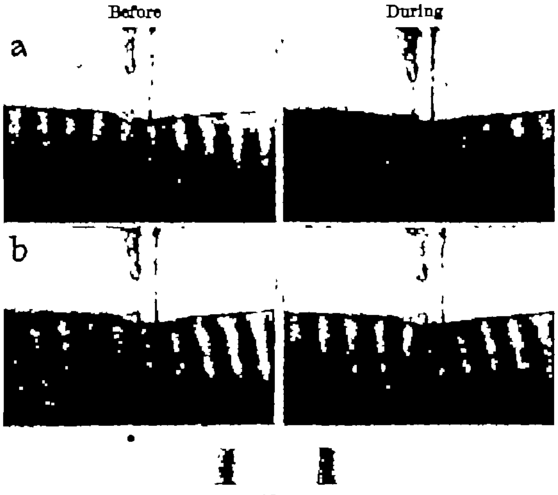

Fig. 1. Micropipette applied to edge of an isolated fibre from the semitendinosus muscle of the frog. Polarized light, compensated so that *A* bands appear dark. In (*a*), pipette is applied opposite an *A* band, in (*b*) opposite an *I* band. Left, before, and right, during, a pulse of current depolarizing the membrane opposite the tip. Contraction in (*b*) only, and then affecting only one sarcomere. In other experiments which were not recorded photographically, the contraction spread about 4 microns inwards

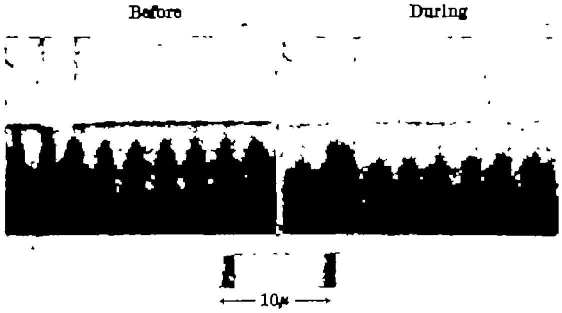

Fig. 2. As in Fig. 1*b*, but with larger pipette. Contraction spreads about 10 microns inwards, but there is no spread to the adjacent sarcomeres, where the *I* bands are, in fact, stretched

We consider that these results are strong evidenc that the influence of membrane depolarization is con veyed to the interior of the fibre by spread along som structure in the *I* band; from the anatomical situatio this must almost certainly be Krause's membrane.

This work was done during the tenure of a fellowshi by one of us (R. E. T.) from the National Institute Neurological Diseases and Blindness, U.S. Publi Health Service.

## Reaction of Starfish Spermatozoa to Histidine and Certain Other Substances considered in Relation to Zinc

Starfish spermatozoa are generally immobile i sea-water suspension. However, Metz[1] has reporte that they become intensely active when they ar suspended in egg albumin – sea water. His exper ments were chiefly concerned with the agglutinatio reaction, and further it was shown (Metz and Donc van[2]) that most of the amino-acids and peptides wer also capable of agglutinating the sperm, whe fertilizin was added. Apart from the problem agglutination, we were interested in the induce motility of these spermatozoa in albumin – sea wate and have examined the effects of various amin acids on their motility and metabolism.

It was found that L-histidine exerts a marke effect on the motility of these spermatozoa. It very striking to take a small amount (0·5 ml.) the diluted sperm (1 : 20) of the starfish, which ar almost motionless, and observe instantly active move ments on addition of 0·5 ml. of histidine – sea wate ($2 \times 10^{-2}$ *M*, *p*H 8·0). At the same time the effec of histidine on the initial oxygen uptake of thes spermatozoa was examined by the usual Warbur technique, at 20° C. and with air in the gas phas As shown in Fig. 1, histidine sharply increases th oxygen uptake, the effect being progressively i creased when sea water containing $10^{-4}$, $10^{-3}$

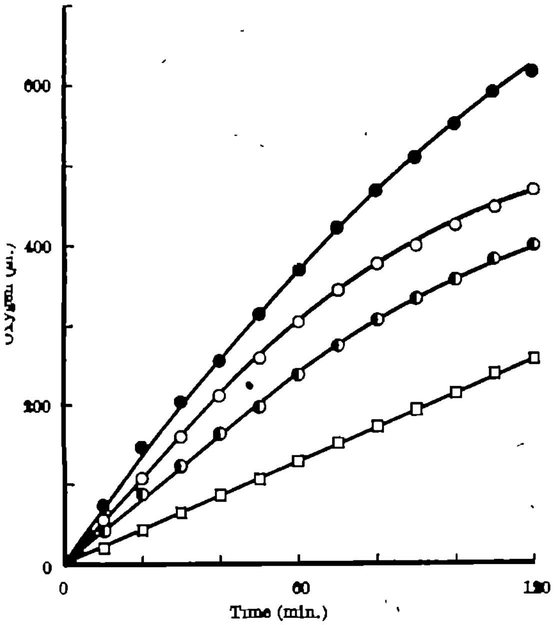

Fig. 1. Effect of histidine on the oxygen uptake of starfish spermatozoa in sea water with different concentrations of histidine: □—□—, control; ◐—◐—, $10^{-4}$; ○—○—, $10^{-3}$; ●—●—, $10^{-2}$ *M* histidine – sea water

$0^{-2}$ *M* histidine is added to sperm suspensions. The otility of spermatozoa is also greatest in $10^{-2}$ *M* istidine – sea water.

Further experiments showed that cysteine and lycine are also effective, the motility and the rate f the respiration of the spermatozoa in cysteine – sea rater being about the same as in histidine – sea water. 'he effect of glycine was very small. Also the helating agents ethylenediaminetetraacetic acid and iethyldithiocarbamate proved to be effective, but he spermatozoa swim less actively in sea water containing these agents than in histidine – sea water. Iowever, it is to be noted that no such effects were roduced when sea water containing other aminocids (alanine, leucine, serine, glutamic acid, arginine, ethionine, cystine, tryptophan, tyrosine) was dded to sperm suspensions.

The question immediately arises whether the xtraordinary effect of histidine is essentially brought bout by the liberation of zinc from the sperm, ince there is evidence that the imidazole group of istidine has a strong zinc-binding capacity (Gurd nd Goodman[3]) and since it has been shown (Fujii[4]) hat zinc is present in considerable amount in some arine sperm, especially in the middle-piece and crosome. That zinc occurs in high concentration n human spermatozoa has also been reported by Iawson and Fischer[5]. Therefore, the zinc content f *Asterias* spermatozoa was determined polarographically and a comparison was made between 1) sperm suspended in sea water for 30 min. and 2) sperm suspended for 30 min. in sea water containing $10^{-2}$ *M* histidine. It was found that the zinc ontent of the spermatozoa was greatly reduced after he treatment with histidine, suggesting that zinc r some zinc compound had passed from the sperm o the external solution. On the average, the zinc ontent of the former (1) was 0·21 μgm./mgm. dry reight, while that of the latter (2) was 0·10 μgm./gm. dry weight. The external medium, which had contained histidine-treated sperm, was found to give a positive dithizone reaction after centrifugation.

The evidence so far obtained suggests that, at least in the starfish, the release of zinc in minute quantities from the sperm is responsible for the initiation of the sperm's activity, both as regards motility and respiration. It is likely that the sperm middle-piece or the acrosome loses zinc to histidine or other metal-chelating substances, and that the liberation of zinc itself represents the sudden release of a state of stress in the spermatozoa. It appears difficult for the present to discuss these results in relation to the dilution effect (Rothschild and Tyler[6]) or the anaerobic motility induced by glycine (Tyler and Rothschild[7]) in sea-urchin sperm. It is interesting, however, to note that the effect of histidine was scarcely observable in a very dilute suspension of the starfish sperm. Could zinc release be normally involved in the basic mechanism of the motility of the spermatozoa?

These experiments described form part of a wider investigation on the physiological role of zinc. One of us (Fujii[8]) has already indicated that zinc is present in appreciable amount in the nucleoli of starfish oocytes, and is possibly involved in the mitotic processes.

## Role of Photochemical Processes in the Reduction of Nitrate by Green Algae

Experiments have been described supporting the idea that reduction of nitrate in the light by green algae is a photochemical process[1]. However, a strong argument against this assumption is the fact that, without carbon dioxide, a really significant reduction of nitrate in the light has never been found[2,3]; only several hours after the addition of glucose can a strong evolution of oxygen due to nitrate reduction be observed[3]. This indicates an indirect influence of light via the formation of photosynthetic products rather than a direct photochemical reduction of nitrate. In the following we show that it is necessary to distinguish between the effect of light on the reduction of nitrate and nitrite, respectively (cf. also Harvey's results with diatoms[4]). The latter is the first intermediate in the reduction of nitrate by green algae[5].

When nitrate is added to *Ankistrodesmus braunii* suspended in nitrogen-free culture medium in the absence of carbon dioxide, only a minute amount of oxygen is evolved (Fig. 1). This result, obtained manometrically under a variety of experimental conditions (*p*H 6·5 and 4·5, under pure nitrogen and air, with $4 \times 10^{-4}$ to $9 \times 10^{-3}$ *M* potassium nitrate,

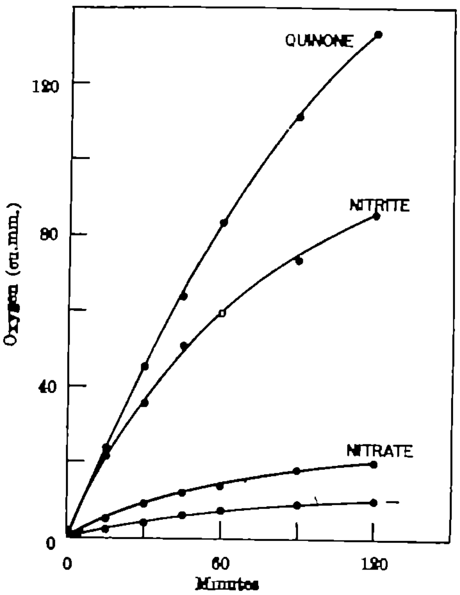

Fig. 1. Oxygen evolution after addition of quinone, sodium nitrite, and potassium nitrate (no addition as control) to *Ankistrodesmus* suspended in nitrogen-free culture medium ($p$H 6·5) in the absence of carbon dioxide. Gas phase, nitrogen (potassium hydroxide in the centre well); light intensity, 1,200-foot candles; temperature, 15° C.; 21 mm.³ cells (6·5 mgm. dry weight) per vessel. Concentrations of oxidants: quinone, 3·3 × $10^{-3}$ *M*; sodium nitrite, 1·1 × $10^{-3}$ *M*; potassium nitrate, 3·3 × $10^{-4}$ *M*. Theoretical yield: 179 mm.³ oxygen in each case. Pretreatment of the algae: 4 hr. in nitrogen-free medium at moderate light intensity (400 ft.-candles); gas phase, air

at 15° and 25° C.), is in excellent agreement with earlier findings[3,4]: The rate of reduction of nitrate under these conditions is approximately the same as that normally occurring in the dark. On the other hand, reduction of nitrate in the presence of carbon dioxide, or in the absence of carbon dioxide with added glucose[5], proceeds about ten times as fast as reduction in the dark[5]. By contrast, an addition of nitrite in non-toxic concentrations produces an immediate strong evolution of oxygen in the light. (Pressure changes are negligible in the presence of alkaline pyrogallol as an oxygen-absorbing agent.) Per mole of nitrite reduced, 1·5 moles of oxygen are formed. The rate of this reaction at $p$H 6·5 is somewhat smaller than that of the quinone–Hill reaction under the same conditions (Fig. 1). But at $p$H 4·5 reduction of nitrite in the light proceeds much faster, the rate of the reaction being nearly identical with that of the quinone–Hill reaction at $p$H 6·5. It is of interest in this connexion to note that the influence of $p$H on the dark-nitrite reduction is also strong but in the opposite direction[5]. Furthermore, it should be mentioned that an addition of nitrite in the dark under aerobic conditions leads to a strong increase in respiratory oxygen uptake[5], whereas under anaerobic conditions no gas exchange occurs.

In order to inhibit enzymatic processes effectively without influencing photochemical reactions possibly involved in the reduction of nitrite, the rate of the reaction under different conditions was studied at low temperatures. Comparison of the results obtained in a series of experiments performed at 4° C. and at 15° C., respectively (Table 1), shows that: (1) the reduction of nitrite at 15° C. in the light proceeds about twice as fast with concomitant photosynthesis as it does in the absence of carbon dioxide; (2) at 4° C. the favourable influence of carbon dioxide and

Table 1. Nitrite (*M* × $10^{-6}$) Reduction by 25 mm.³ *Ankistrodesm* Cells in 1 hr. at $p$H 4·5. Sodium Nitrite (5·5 × $10^{-4}$ *M*) added Algae in Nitrogen-free Culture Medium. Nitrite Concentration measured Colorimetrically. Experimental Conditio otherwise as indicated in Fig. 1

| | Light | | Dark | |
|---|---|---|---|---|
| | $N_2$ + 4% $CO_2$ | $N_2$ | Air | $N_2$ |
| 15° C. | 212 | 108 | 40 | 20 |
| 4° C. | 110 | 90 | 20 | 8 |

photosynthesis on reduction of nitrite largely di appears; (3) the rate of reduction in the light wit out carbon dioxide is only slightly decreased at 4° C (4) light under anaerobic conditions in the absen of carbon dioxide is much more effective in nitri reduction than is respiration[5] in the dark; this hol true especially at 4° C., where the rates of enzymat reactions are strongly decreased.

Considering these results, one might at first l inclined to conclude that the reduction of nitrite is simple photochemical process with nitrite acting lik quinone as a Hill reagent. There are, howeve some fundamental differences between the reductio of nitrite and a typical Hill reaction. Isolate chloroplasts, able to reduce quinone and other Hi reagents, are unable to reduce either nitrate[6] (unle nitrate reductase and triphosphopyridine nucleotid are added[7]) or nitrite[6,7]. Furthermore, the rate c nitrite reduction in the absence of carbon dioxid by whole *Ankistrodesmus* cells decreases faster tha that of quinone reduction (Fig. 1). Upon a secon addition of quinone, oxygen evolution immediatel starts again at a high rate; with nitrite, howeve only a small increase in oxygen formation is observe The rate of nitrite reduction is apparently determine by the supply of carbon compounds necessary for th further assimilation of the products of nitrate an nitrite reduction[8].

Accordingly, the influence of light upon nitrat reduction in green algae might be explained in th following way. The first step (nitrate → nitrite) which proceeds rapidly only in the presence of carbo dioxide or of glucose[5], seems to be indirectly acceler ated by light via the formation of photosyntheti products. On the other hand, the reduction c nitrite, which goes on at a high rate even at ver low temperatures and in the absence of carbo dioxide, seems to be more closely connected wit photochemical processes.

A full account of these and other results wi be published later. My thanks are due to the U.S National Academy of Sciences and to Foreig Operations Administration for a research scholarship

# Respiratory Increase and Phosphorus and Nitrogen Metabolism in Sweet Potato Infected with Black Rot

IN the black rot of sweet potato caused by *eratostomella fimbriata* we found a respiratory inrease—a characteristic of plant tissues infected with athogens. We have investigated the rate of respiraory increase in the sound part next to the infected issues during a week after the inoculation of the athogen, the effect of 2,4-dinitrophenol on the espiration and the changes in the amount of phoshorus and nitrogenous compounds present.

In contrast to the constant respiration in the ontrol and the equal rate of respiratory increase about 80–90 per cent) caused by addition of dinitrohenol, the increase of respiration in tissue affected y black rot reached a maximum (about 90–100 per ent increase) at 48–72 hr., and gradually decreased hereafter; the respiratory increase due to addition f dinitrophenol dropped to c. 30 per cent at 48–72 hr., ut recovered again at a later stage.

able 1. RESPIRATION OF THE BLACK-ROT TISSUE OF SWEET POTATO AND THE EFFECT OF DINITROPHENOL

wenty slices (7 mm. in diameter and 0·5 mm. thick) were put into he Warburg vessels containing 85 µmoles of phosphate buffer (pH 5·5) nd 162 µmoles of sucrose in a total volume of 2·0 ml. Gas phase, air; emperature, 30°; 20 min. equilibration; dinitrophenol was added in a final concentration of 5 × $10^{-5}$ *M*

| (hr.) | 0 | 24 | 48 | 72 | 168 |
|---|---|---|---|---|---|
| Control (µl.) | 77·3 | 88·0 | 80·5 | 77·6 | 93·7 |
| Control + DNP | 138·7 | 156·0 | 143·0 | 149·0 | 178·0 |
| Increase (%) | 80 | 77 | 78 | 92 | 90 |
| Black rot (µl.) | | 132·7 | 147·0 | 177·0 | 120·0 |
| Black rot + DNP | | 208·0 | 186·0 | 232·0 | 231·0 |
| Increase (%) | | 56 | 26 | 31 | 93 |

Since the respiratory increase due to dinitrophenol s dependent on the acceleration of the reaction ATP → ADP + $P_i$), its effect indicates the speed of he above reaction in tissues. It is supposed that, herefore, the decrease of the effect in one stage may e caused by the promotion of breakdown and/or tilization of adenosine triphosphate by some bioogical process. To clarify this point the tissues were nalysed for inorganic phosphate and acid-soluble rganic phosphate. Both phosphate fractions of the ontrol remained almost constant, whereas inorganic hosphate in black rot tissue decreased at first, ncreased in the second stage, and then dropped gain; a concomitant increase of acid-soluble rganic phosphate was observed. Occasionally was observed that the level of inorganic phoshate in the secondary stage was not raised but emained constant. There was no measurable hange in the alcohol-soluble phosphate fraction conaining phospholipid and the phosphate fraction xtractable with cold perchloric acid and containing ibonucleic acid. The accumulation of acid-soluble rganic phosphate may indicate the activation of a hosphate system by which the energy of adenosine riphosphate is utilized and the rate of generation f adenosine diphosphate is increased; thus the ncreased respiration in the black-rot tissue of sweet otato may be linked to the activated phosphate ystem.

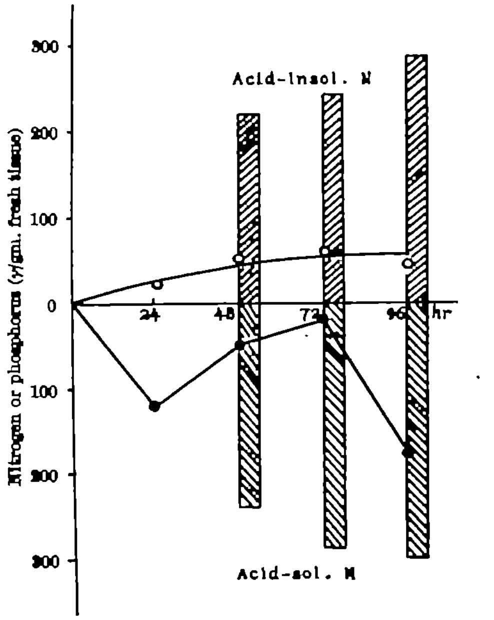

Fig. 1. Change of the amounts of phosphorus and nitrogenous fractions in the sweet potato infected with black rot. Inorganic phosphate, —●—, is expressed as the difference between the control and that of black-rot tissue; acid-soluble organic phosphate, ○—○, as the difference between that in black-rot tissue and that in the control. In the same way, acid-soluble nitrogen shows the decrease and acid-insoluble nitrogen the increase over the control. The values for the controls scarcely changed through the experimental stage

To elucidate the anabolic process such as the ctivation of the phosphate cycle in the black-rot issues, we have examined the nitrogenous metaolism. Compensating the consumption of the acid-soluble nitrogenous fraction (such as amino-acids), a concomitant increase of the acid-insoluble nitrogenous fraction (such as protein) was observed; in further experiments, the synthesis of functional protein such as mitochondrial protein was observed.

The mechanism of the respiratory increase in the black-rot tissues is thought to be as follows: by the penetration of *Ceratostomella fimbriata*, the protoplasm of the sound part next to the infected tissue is activated to synthesize organic phosphate, functional proteins such as mitochondria, and simultaneously accelerates the adenosine phosphate reaction (ATP → ADP + $P_i$); this results in an increase of respiration. P. J. Allen[1] believed that the respiratory increase in wheat infected by powdery mildew could be explained by the mildew toxins acting as uncouplers and accelerating the production of adenosine diphosphate. We have put forward the view that a part of the respiratory increase might be caused by the uncoupling effect of ipomeamaron, a sesquiterpene $C_{15}H_{22}O_3$, and related substances accumulated in the infected sweet potato tissues[2]; but from the above results it is thought that the effect of uncouplers such as ipomeamaron may be only partly responsible for the respiratory increase. As these uncouplers acted as inhibitors of the phosphate metabolism and protein synthesis of *Ceratostomella fimbriata*, they were presumed to take part in the resistance of sweet potato against the pathogen[3].

The metabolites (essential oils (such as ipomeamaron), polyphenols (for example, chlorogenic acid), coumarin substances (for example, umbelliferon and scopoletin)) were accumulated in the sound tissue, paralleling the respiratory increase[4], and offered resistance to infection by the pathogen. In addition, a thermolabile and non-dialysable fraction containing an inhibitor is produced in the black-rot tissues[5].

Those effects were also observed in white potato tissue, which shows strong resistance against *Ceratostomella fimbriata* infection[3]; the acid-soluble organic phosphate and acid-insoluble nitrogenous compound were synthesized, and at the same time the respiration was increased (c. 40 per cent). In the white potato rot-tissue, the thermolabile, non-dialysable fraction inhibited germination of the fungal spores. K. Tomiyama *et al.* have described a similar effect in the white potato infected with *Phytophthora infestans* and offered a similar explanation, independently, before a meeting of the Phytopathological Society of Japan (April 6, 1955).

We wish to express our thanks to Dr. Yusuke Sumiki, University of Tokyo, for his advice.

# Molecular Weight of Insulin in N,N-Dimethylformamide

The detailed investigations of Sanger and co-workers have established the molecular weight of insulin as some multiple of about 6,000[1]. It is not clear, however, whether the fundamental covalently bonded unit is the 6,000 or 12,000 species. (The determination of the positions of the S—S linkages in insulin[1] does not establish the fundamental unit as the 6,000 species. The methods of analysis do not preclude the possibility of a staggered arrangement of the S—S linkages such that the 12,000 species is covalently bonded together.) Several workers using a variety of techniques—osmotic pressure, sedimentation and light-scattering—achieved results indicating that the minimum molecular weight of insulin in aqueous solution is 12,000[2]. However, other work has indicated a value of 6,000. Harfeneist and Craig[3], by counter-current distribution methods in 2-butanol-dichloracetic acid systems, Fredericq[4] by sedimentation-diffusion studies in alkaline solutions, and Kupke and Linderstrøm-Lang[5] by osmotic pressure determinations in aqueous guanidine chloride solutions, have all recently contributed data consistent with the value of 6,000. Osmotic pressure studies of insulin in N,N-dimethylformamide in this laboratory also indicate a molecular weight of 6,000 for the fundamental unit.

Amorphous insulin (lot 200-1*B*-11*J*) was a gift of the Eli Lilly Company. N,N-Dimethylformamide (DuPont) was purified by distillation at reduced pressure through an activated charcoal column. Although it has a relatively low dielectric constant of 26·6, the osmotic pressure studies were made in 0·2 *M* potassium iodide solutions of N,N-dimethylformamide in order to minimize an possible Gibbs–Donnan effect. Zimm–Myerso osmometers[6] were used with suitably permeab membranes prepared from Visking cellulose casin by a treatment which included an 18-hr. soak i 80 per cent ethanol. The osmometers were place in solvent inside closed glass jars to prevent al sorption of water. Equilibrium was attained i about two days and measurements were made f at least three days longer. The temperature wa 13·8° C. and was regulated to ± 0·01° C.

Table 1

| Insulin conc. (gm./L.)* | $\pi$ (cm. $H_2O$) | $\bar{M}_n \times 10^{-3}$ |
|---|---|---|
| 0·36 | 1·29 | $6·7_6$ |
| 0·46 | 1·64 | $6·8_5$ |
| 0·88† | 3·15 | $6·8_4$ |
| 0·92 | 3·02 | $7·4_6$ |
| 0·92 | 3·06 | $7·3_4$ |
| 0·92 | 3·13 | $7·1_4$ |
| 1·49 | 5·04 | $7·1_6$ |
| 1·79 | 5·82 | $7·4_7$ |
| 1·79 | 6·03 | $7·2_5$ |

* In 0·2 *M* potassium iodide in N,N-dimethylformamide.

† In 0·1 *M* sodium nitrate in N,N-dimethylformamide.

The data from these experiments (Table 1 an Fig. 1) extrapolate to a molecular weight of 6,200 ± 300 at $C = 0$. Assuming that the deviation fro ideality at higher concentrations is entirely due to monomer–dimer equilibrium, $2I \rightleftharpoons I_2$, we calculat an association constant of $2 \times 10^3$ litre-mol.$^{-1}$, corresponding to $\Delta F^\circ = -4·4$ kcal./mol.

The question arises as to whether the fundamenta structure of insulin is disrupted in N,N-dimethylformamide. Facilities for an assay of the activity o insulin recovered from it were not available. However, the following test was applied. It is well know that insulin aggregates to a considerable extent i aqueous solution, and the extent of this aggregation measured by the sedimentation-rate, is presumabl a characteristic of the unaltered molecule. Sedimentation experiments were therefore performed o insulin, which, after solution in N,N-dimethyl formamide, was dialysed against phosphate buffer *p*H 7·5, Γ/2 0·1, in which it was completely soluble Experiments were also performed with insulin dissolved directly in this buffer, for comparison. Withi experimental error, there was no difference betwee the sedimentation constants, $S^W_{20}$ (Table 2), for th original and the recovered insulin.

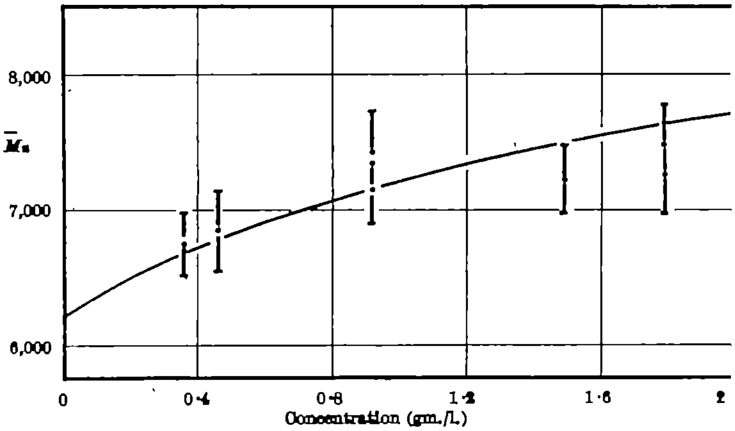

Fig. 1. Apparent number-average molecular weight of insulin in N,N-dimethylformamide as a function of concentration. The theoretical curve for a monomer–dimer equilibrium, with an association constant of $2 \times 10^3$ l./mol.$^{-1}$, is drawn through the data

Table 2

| Sample of insulin | $C$ (gm./l.) | $S_{20}^{w}$ (svedbergs) |
|---|---|---|
| Dissolved directly | 5·1 | 3·3 |
| | 2·9 | 2·9 |
| Recovered from N,N-dimethylformamide | 5·1 | 3·1 |
| | 2·5 | 2·8 |

Although minimal molecular weights of 6,000 and .000 have been reported, there is no inconsistency cessarily involved. The value of 12,000 has been ·md in aqueous solutions, in which it is not unlikely at the dimer persists. Two reports of the value 000 have now been obtained independently by arfenist and Craig[4] and in this communication, in n-aqueous solvents, in which the aggregation actions are apparently less favoured, and the true inimal molecular weight is observed.

This work is part of a study of the solubilities and operties of proteins in non-aqueous solvents, which ll be reported in detail elsewhere.

# Inhibition of Complement Activity by Di-*iso*propyl Fluorophosphate

IT is generally agreed that di-*iso*propyl fluoro- 1osphate acts specifically to inhibit enzymes with terase activity[1]. In the light of this conclusion, e finding that it inactivates guinea pig complement ′) is felt worthy of this brief communication. (In personal communication, Dr. Laurence Levine ported that he has independently observed this me finding.)

When di-*iso*propyl fluorophosphate in concentrations ' $8{\cdot}0 \times 10^{-8}$ to $1{\cdot}0 \times 10^{-4}$ *M* was incubated with luted or undiluted guinea pig serum up to 4 hr. 37° C., or overnight at 26° or 4°, and then the rum diluted and tested for complement activity, effect of the fluorophosphate could be detected. 'hen, however, $8{\cdot}0 \times 10^{-8}$ *M* di-*iso*propyl fluoro- 1osphate was incubated for ½ hr. at 37° with varying ncentrations of 1–100 diluted guinea pig serum in e presence of sheep cells sensitized with rabbit emolysin, 75–80 per cent inhibition of the hæmolytic tivity of complement was noted. In the same rcumstances, $3{\cdot}5 \times 10^{-8}$ *M* di-*iso*propyl fluoro- hosphate gave 10 per cent inhibition. On testing e dialysed supernatants from the latter reaction r the presence of the four components ($C'1$, $C'2$, '3, $C'4$) of complement by the usual methods[2], only e first component ($C'1$) was found to have been opreciably inactivated.

That the effect of di-*iso*propyl fluorophosphate is 1 $C'1$ was confirmed by using sensitized sheep cells ntaining the first, second and fourth components 'a $C'1$, 4, 2). These were prepared as described by Levine *et al.*[3] and incubated overnight at 30° with di-*iso*propyl fluorophosphate, then washed, resuspended in buffer and tested for activity with reagents specific for the respective components. As can be seen in Table 1, the concentrations required for inhibition of the $C'1$ activity of these cells varied from $2{\cdot}7 \times 10^{-8}$ to $8{\cdot}3 \times 10^{-8}$ *M*. This is considerably less than the molar concentrations ($8{\cdot}0 - 3{\cdot}5 \times 10^{-8}$) required for inhibition of $C'$ for whole serum. The $C'4$ activity was not affected by this treatment. The effect of di-*iso*propyl fluorophosphate on $C'2$ could not be tested, since $C'2$ was spontaneously inactivated on standing in buffer alone. Partial reversal of the inhibition of $C'1$ activity could be obtained by allowing the cells treated with fluorophosphate to stand overnight in the presence of 0·1 *M* nicotinohydroxamic acid[4].

Table 1. INHIBITION OF $C'1$ ON $EAC'$ 1, 4, 2, INCUBATED WITH DI-*iso*PROPYL FLUOROPHOSPHATE

$1{\cdot}0 \times 10^{8}$ cells/ml. were incubated at 30° C. overnight with saline–veronal–bicarbonate buffer to which was added the di-*iso*propyl fluorophosphate, 0·001 *M* calcium ions, 0·003 *M* magnesium ions, and 0·04 *M* imidazole buffer *p*H 7·6. The cells were then centrifuged, washed, resuspended in buffer and reacted with $R_1$, the reagent for testing the $C'1$ reaction (ref. 2).

| | | | | | |
|---|---|---|---|---|---|
| Molar concentration of DFP ($\times 10^{8}$) | 270 | 41 | 21 | 8·3 | 0 |
| Time (min.) required to attain 50 per cent hæmolysis | > 30 | 20 | 9 | 4 | 1 |

From this it is concluded that the first component of complement $C'1$ is an enzyme with esterase activity which exists in serum in a precursor form resistant to the action of di-*iso*propyl fluorophosphate. In the course of the immune hæmolysis reaction, the $C'1$ precursor is changed to an active form of $C'1$ which is now capable of being inhibited by the fluorophosphate. The $C'1$ on the 1, 2, 4 cells apparently exists in such an active form, or was possibly changed into such an active form, during incubation with the fluorophosphate.

I am grateful to Dr. C. T. Harwood and to Dr. Bernard Jandorff for supplies of di-*iso*propyl fluorophosphate, and to Dr. I. B. Wilson for a sample of nicotinohydroxamic acid.

# Occurrence of an L(+)-Alanine-Dehydrogenase in *Bacillus subtilis*

THE metabolic analysis of mutant strains of *B. subtilis* has shown that the ability to use the ammonium ion as the sole source of nitrogen for growth corresponds to the presence of a glutamic-dehydrogenase[1]. However, a mutant unable to use the ammonium ion (strain $S^{-}$), lacking glutamic-dehydrogenase, oxidizes glutamic acid very actively. This strain may grow, with aeration, in a culture medium containing: *l*(+)-glutamate 0·01 *M*, ammonium sulphate 0·01 *M*, phosphate buffer ($KH_2PO_4$–$Na_2HPO_4$) 0·02 *M*, *p*H 7·5, sodium chloride 0·01 *M*, potassium sulphate 0·01 *M*, magnesium sulphate 0·001 *M* and ferric citrate 0·0004 *M*.

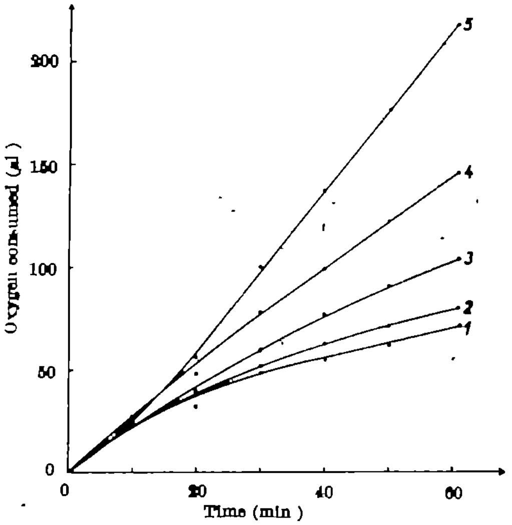

Fig. 1. Oxidations followed with a Warburg apparatus at 35° C. Each vessel contains: 2·0 ml. cell suspension (optical density 2·16) in 0 05 *M* phosphate buffer, *p*H 6 7; 0·2 ml. 5 *N* sodium hydroxide in the central cup. Curve 1, without substrate. Additions: curve 2, 100 μmole glycine; curve 3, 100 μmole *l*(+)-aspartate; curve 4, 100 μmole *l*(+)-alanine; curve 5, 100 μmole *l*(+)-glutamate

The absence of the glutamic-dehydrogenase in the $S^-$ strain implies an oxidative pathway of glutamic acid different from the ordinary one.

α- and γ-Aminobutyric acids are slowly oxidized by this bacterium, and the test for glutamic-decarboxylase in extracts is negative. This finding suggests that an oxidation preceded by a decarboxylation is not operative in this case. Another possibility might be the oxidation of a compound formed by transamination of glutamic acid, according to reactions (1) and (2):

$$\text{Glutamic acid} + R\text{—CO—COOH} \rightleftharpoons R\text{—CH(NH}_2\text{)—COOH} + \alpha\text{-ketoglutaric acid} \quad (1)$$

$$R\text{—CH(NH}_2\text{)—COOH} + O_2 \rightarrow R\text{—CO—COOH} + H_2O + NH_3 \quad (2)$$

$$\text{Glutamic acid} + O_2 \rightarrow \alpha\text{-ketoglutaric acid} + H_2O + NH_3 \quad (3)$$

In this system, α-ketoglutaric acid is used as the source of carbon for growth. The α-keto-acid, which is the acceptor of $-NH_2$, is regenerated by oxidation. This mechanism implies that the α-keto-acid originates from cell reserves, and is not lost by any secondary reaction. These restrictive conditions are not necessary if the α-ketoglutaric acid can regenerate the α-keto-acid. If we suppose that the α-ketoglutaric acid is oxidized through the Krebs cycle, the *R*—CO—COOH compound could be oxalacetic acid or its decarboxylation product, pyruvic acid, or glyoxylic acid arising from the decomposition of citric acid[8]. In this case, *R*—CH(NH$_2$)—COOH would be aspartic acid or alanine or glycine. Of these three substances, alanine is readily oxidized, aspartic acid is less oxidized and glycine almost not at all (Fig. 1).

*B. subtilis* $S^-$ cells, grown on the medium describ before, harvested when in the exponential phase, a treated with lysozyme[3], give an extract which is n able to absorb oxygen. The utilization of oxygen reinforced by addition of alanine and, to a less degree, by aspartic or glutamic acid. This oxyg consumption could result from the presence of flavoproteic *l*-amino-acid-oxidase, such as in *Neu spora crassa*[4], which oxidizes *l*(+)-alanine, *l*(- phenylalanine and, less actively, glutamic acid a aspartic acid. However, an extract prepared fro 12·5 mgm. lyophilized bacteria per ml., treated wi lysozyme and centrifuged at 80,000 *g* for 45 mi gives a clear supernatant which does not oxidi *l*(+)-alanine with oxygen, but in which the alani intensively reduces diphosphopyridine nucleoti (DPN+). The same extract, precipitated ammonium sulphate at saturation, redissolved a dialysed against phosphate buffer (0·05 *M*, *p*H 7· gives the activity reported in Fig. 2.

*l*(+)-Glutamic acid, *l*(+)-aspartic acid, *l*(– phenylalanine and *l*(–)-leucine have no actio Triphosphopyridine nucleotide is not reduced in t same conditions.

As shown in Fig. 2, the maximum reduction diphosphopyridine is a function of the concentrati of alanine. An equilibrium is obtained, as is al evident from the re-oxidation brought about addition of ammonium ions and to a lesser degr by hydrogen ions. The oxidation product of *l*(+ alanine is pyruvate. By incubation, during 30 mi at room temperature and *p*H 8·75, of a mixture 0·4 ml. of extract, 20 μ*M* of *l*(+)-alanine and 0·36 μ of diphosphopyridine and 0·4 ml. of pyrophospha buffer 0·1 *M* in a total volume of 1 ml., 0·31 μ*M* pyruvate is formed. The pyruvate gives a reoxid tion of the diphosphopyridine of the same magnitu as the ammonium ion.

One can conclude that the extract contains e enzyme which catalyses the reversible reaction (4

$$CH_3\text{—CH(NH}_3\text{)}^+\text{—COO}^- + DPN^+ + H_2O \rightleftharpoons CH_3\text{—CO—COO}^- + DPNH + H^+ + NH_4^+ \quad ($$

This enzyme may be called '*l*(+)-alanine-dehydr genase', in conformity with *l*(+)-glutamic-dehydr

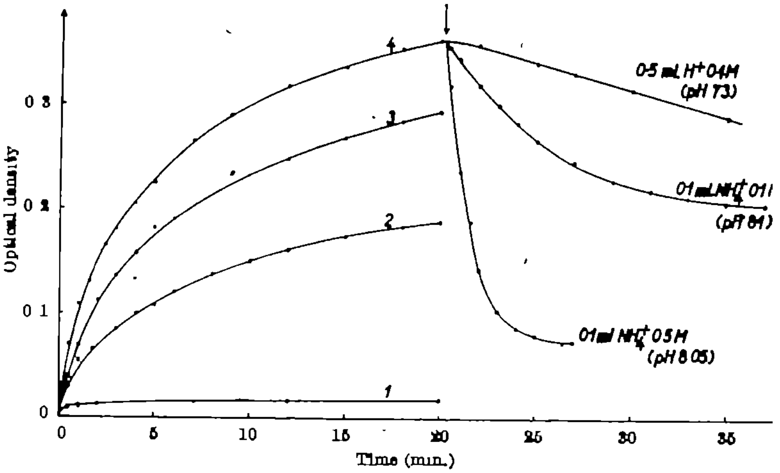

Fig. 2. *l*(+)-Alanine dehydrogenation followed by change in optical density of diphosphopyridine nucleotide at 340 mμ, with a Beckman Model *D.U.* spectrophotometer, at room temperature. The reaction mixture contained: 0 5 ml. cell-free extract, 0·5 ml. 0·1 *M* sodium pyrophosphate, 1 0 ml. 0·1 *M* phosphate buffer, *p*H 7·3; final *p*H, 8·1. Curves 1, 2, 3 and 4 correspond respectively to 0, 2, 5 and 10 μmole of *l*(+)-alanine in a volume of 0·5 ml. At zero time, 0·3 ml. of 0 001 *M* diphosphopyridine nucleotide is added. At the arrow, addition of ammonium ion and hydrogen ion as indicated on the curves. Values are corrected for dilution by the different additions

ıase, the only comparable enzyme known. Like former, this enzyme is very specific, since it does t act on $d(-)$-alanine and the other compounds ited.

Ihe reversibility of reaction (4) shows that this zyme is important, not only in the oxidation of +)-alanine, but also in the assimilation of ammonium. Although the assimilation of ammonium s only been shown to occur through glutamic-hydrogenase[1], other observations suggest that ferent mechanisms may exist[5].

The $S^-$ strain used in this work does not grow on nine as sole nitrogen source, and in this case the ination of pyruvic acid by ammonia is not erative.

## Action of Ribonuclease on Living Cells *in vitro* and Synthesis of Deoxyribonucleic Acid

THE action of ribonuclease on living cells from arious materials has recently been studied[1,2]. Chick broblasts and myoblasts *in vitro* are readily affected; rowth of the cultures and the number of mitoses re considerably reduced[2]; cytoplasmic and nucleolar asophilia is diminished or suppressed and a typical odification of the chromatin, seen both with phase-ontrast optics in living cells and on fixed preparaions, is observed. Many nuclei (up to 95 per cent hen the action of ribonuclease has been particularly ntense) contain granular, or granular and filamentous, aterial or even are prophasic in appearance[3]. Even hen many nuclei are showing this prophasic aspect, ew—if any—other mitotic stages are encountered.

Histospectrophotometric measurements were unlertaken to assess how the hydrolysis of ribonucleic oid affected deoxyribonucleic acid metabolism. The quipment and techniques used for quantitative Feulgen determination after osmium fixation will be lescribed in detail elsewhere. They are essentially imilar to those of the Pollister and Leuchtenberger chool. Measurements of randomly chosen internitotic nuclei (all non-overlapping nuclei in a straight ine tangential to original explants, several explants being used for each group) were measured at 546·1 mμ. The most striking results were obtained with cultures which had had a long contact (3 days) with ribonuclease (crystallized ribonuclease G.B.I.). In Fig. 1, the histogram for such cultures is compared to normal controls of the same age. There is a considerable decrease in the percentage of the cells with a normal diploid value (1·82 ± 0·17 in arbitrary units) and a considerable increase in the number of cells with a tetraploid (3·65) or intermediate value. Other cultures in contact with ribonuclease for a shorter time (15 hr.–2 days) show a similar but less marked shift in deoxyribonucleic acid values.

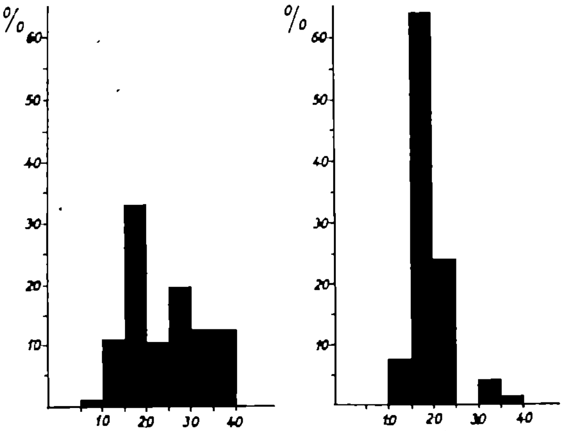

Fig. 1. Histograms of deoxyribonucleic acid values (arbitrary units) in intermitotic nuclei of 3-day old chick fibroblasts and myoblasts cultures. On the left, cultures treated with ribonuclease (1/300) in the medium (number of measurements, 108). On the right, controls of the same age (number of measurements, 81)

It should be emphasized that the granular distribution of deoxyribonucleic acid in many of the affected cells increases the heterogeneity of the dye distribution in the nucleus, and thus the measured extinction is lower than it would be if the same material was as homogeneously distributed as it is in the controls. A number of deoxyribonucleic acid values can be considered as too low, and the difference from the controls is certainly more marked than the histogram shows. In order to eliminate this lowering of values due to heterogeneity and to be able to measure prophasic or pseudoprophasic nuclei, we have used the two wave-lengths method of Patau[4] on some of these. This technique is more accurate but slower, and cannot be applied to all nuclei in our conditions. Measurements were made at 485 ± 20 mμ and 515 ± 20 mμ. Results are transformed into the units used above by a correction factor. All the prophasic nuclei measured by this technique in treated cultures proved to be tetraploids, and some very granular nuclei showed similarly high values.

As the treated cultures contain fewer mitotic figures (other than arrested prophases) than the controls, the difference between them is not due to a higher rate of cell multiplication in the treated cultures. Indeed, in an actively growing culture, the histogram has still another shape: a tetraploid peak of up to 15 per cent of cells is found with but few intermediate values. The effect observed is still different from that found in colchicine-treated cultures, where tetra- and octoploid nuclei appear as the result of mitoses interrupted at metaphase by spindle inhibition[5].

It appears that removal of cellular ribonucleic acid by ribonuclease does not prevent the synthesis of deoxyribonucleic acid by the cells before prophase, but inhibits further development of mitosis. We have thus a true prophasic inhibition of mitosis. It can be concluded that ribonucleic acid is not involved in the synthesis of deoxyribonucleic acid but is in some way necessary to the normal mitosis in this material.

This work, including comparison with other materials, will be reported more fully elsewhere.

# A Critical Method of measuring the Diameter of Living Bacteria with the Interference Microscope

With an ordinary microscope, the accuracy of measurement is limited by the numerical aperture of the optical system and the wave-length of the light used, and it is scarcely possible to determine the dimensions of an object more accurately than to the nearest 0·4μ. Consequently, the size of very small objects such as living bacteria can only be estimated roughly by direct measurement.

With the interference microscope, however, it is possible to measure very critically the amount by which the light is changed in phase as it passes through an object, and, since this phase-change is proportional to the product of the object's refractive index and thickness, it should be possible to measure its thickness with considerable accuracy if its refractive index were known. One would no longer be limited in accuracy by the wave-length of the light used.

It is, in fact, possible to measure the refractive indices of many living bacteria quite accurately by the method of immersion refractometry developed in 1952 by R. Barer and his collaborators[1]: and so an attempt was made to combine this method with interferometry to obtain an accurate estimate of the mean thickness of a living bacillus.

The organism selected was *Bacillus bulgaris*, cultures of which were obtained from the Yalacta Laboratories in Paris. When measured with an eyepiece micrometer, it always appeared to be between 1μ and 1·5μ in diameter, both in the original cultures and in the subcultures grown from them. The refractive indices of all the bacilli were found to lie between 1·4000 and 1·4090 in each of the cultures investigated; and, when suspended in a bovine plasma–albumin solution that had a refractive index of 1·4045, approximately equal numbers of dark and bright bacilli were visible under the phase-contrast microscope. This figure was therefore taken as their mean refractive index.

Bacilli were suspended in a 0·25 per cent sodium chloride solution for examination with the interference microscope. This suspension-fluid was assumed, as a result of a previous investigation[2], to have a tonicity approximately equivalent to the above-mentioned bovine plasma solution, and it h a refractive index of 1·3350. The double-refracti interference microscope of Messrs. Charles Baker Holborn was used, and measurements were ma with a 2-mm. double-focus objective in conjuncti with the recently developed half-shade matching ey piece described by Smith[3]. Light from a 'Pointolit lamp was used, filtered through an Ilford 807 filt which gave a narrow green spectrum with a maximu intensity at about 542 mμ. With this arrangemen it was possible to measure the phase-changes caus by bacilli lying with their long axes at right angl to the optical axis of the microscope to the neare 1/60 wave-length, or more accurately than this.

It was, however, necessary to apply a sma correction to these recorded measurements, becau the bacilli were too small for any intensity differenc to be appreciated between their edge and midd line; which their cylindrical cross-section would lea one to expect. Thus, each phase-change recorde represented the integrated phase-change over th whole object, such as would be caused by its *mea* thickness as opposed to its *maximum* thickness. Th mean thickness of an object of circular cross-sectic is equal to the length of the side of a square equ in area to the circle: and a correction of $\times \frac{2}{\sqrt{\ }}$ or approximately × 1·13 must therefore be applie

Ten measurements of the phase-change were mad on different bacilli in each culture studied, and th mean taken. The mean thickness, *t*, of the bacil in each preparation was then calculated from th formula:

$$t = 1{\cdot}13 \times \frac{\varphi}{360} \times \frac{\lambda}{n-m}$$

where $\varphi$ was the measured mean phase-chang expressed as an angle, $\lambda$ the mean wave-length o the light used (542 mμ), $n$ the mean refractive inde of the bacilli (1·4045), and $m$ the refractive inde of the saline mounting medium (1·3350).

Table 1

| *Bacillus bulgaris* culture (date) | Mean $\varphi$ (degrees) | $t$ ($\mu$) |
|---|---|---|
| Paris, 11/7 | 55·8 | 1·37 |
| Paris, 11/7; subcultured, 16/7 | 55·4 | 1·36 |
| Paris, 11/7; subcultured, 24/7 | 52·6 | 1·29 |
| Paris, 25/7 | 52·8 | 1·29 |
| Paris, 25/7 | 53·2 | 1·30 |
| Paris, 25/7; subcultured, 27/7 | 52·2 | 1·28 |
| Paris, 25/7; subcultured, 27/7 | 53 6 | 1·31 |
| Paris, 25/7; subcultured, 27/7 | 52 0 | 1·28 |
| Paris, 25/7; subcultured, 27/7 | 54·4 | 1·33 |
| Paris, 25/7; subcultured, 27/7 | 53·6 | 1·31 |

Table 1 shows the values for the mean phase change and thickness obtained in ten different preparations, including cultures and subcultures o several different dates. Each figure in the table is the mean of ten observations. It will be seen tha the mean thicknesses thus calculated vary from 1·28μ to 1·37μ: a maximum scatter of only 0·09μ. It is evident that the diameter of the bacilli in the various cultures is remarkably uniform. The limit to the accuracy of this method is presumably set by the accuracy with which $\varphi$ can be determined.

I wish especially to thank Dr. J. R. Baker, of the Cytological Laboratory, Department of Zoology, Oxford, and Mr. F. H. Smith, of Messrs. Charles Baker, Holborn, for much valuable criticism and advice. Most of the apparatus used was provided

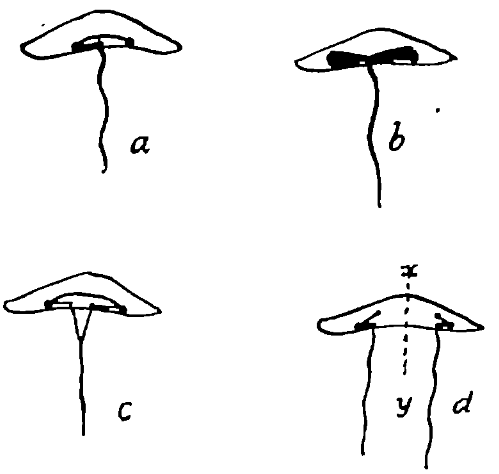
## Taxonomic Position of the Genus *Selenomonas* (von Prowazek)

In a recent analytical review[1], Lessel and Breed ve reiterated the conclusions of Boskamp[2] upon bacterial nature of *Selenomonas palpitans* (Simons, Boskamp). Although they do not add materially the information available, these authors state that *lenomonas* clearly belongs to the family Spirillaceae. I have studied the morphology both of *Selenomonas lpitans* from the guinea pig caecum, and of *S. utigena* from the human mouth, and am of the inion that the nuclear structures, flagellation and de of cell division are entirely unlike those of cteria and reflect a much closer relationship with protozoa.

The nucleus consists of a filament with expanded ds, one of which is connected by a rhizoplast to the pharoplast, from which arises the flagellum, usually the centre of the concave side of the crescentic cell. e nucleus and a portion of the neuromotor appara- s are embedded in deeply staining basophilic asses, in the form of two cones, point to point ig. 1,*b*). When the nucleus divides, a second rhizo- st appears, joining the blepharoplast to the free d of the nuclear filament. The blepharoplast vides, initiating division of the flagellum, and the vision of the nucleus follows (Fig. 1,*c*). The cell en divides by constriction. This is entirely unlike y known scheme of nuclear division in bacteria[3]. The cell wall fails to stain in the characteristically cterial manner with tannic acid and crystal violet, with phosphomolybdic acid and methyl green[3,4], d the cell lacks the cross-walls which are found in many bacteria, including spirilla[3]. The flagellum, when compared with those of bacteria in the same field of the electron microscope, was entirely distinct in its appearance. It is composed of numerous tiny fibrils, like the flagella of protozoa, and unlike either the monofibrillar flagella of bacteria or the compound flagella of certain spirilla[3]. The flagellum of *Selenomonas* is also distinct from that of bacteria in that it can be demonstrated in the light-microscope by staining with Giemsa or simple dyes without previous mordanting. The frayed 'whip-tuft' appearance shown by Boskamp[2] and others is an artefact, due to unsuitable technique. The cell moves in an irregular tumbling course, which once more is more reminiscent of protozoa than of bacteria.



ig. 1. (*a*) Nuclear structure in an adult cell of *S. palpitans*. b) Masking basophilic materials often confused with the nucleus roper. (*c*) Division of nucleus and splitting of flagellum. d) Nuclear division completed, cell now divides by constriction along *x*—*y*

These findings indicate clearly that the affinities of the genus *Selenomonas* are with the Protozoa. The classification of Wenyon[5], which places it in the family Monadidae (Kent), is adequate to the present extent of our information.

## Paper Chromatographic and Biological Properties of Reserpine and Related Compounds

Little is known of the metabolism (in man and experimental animals) of the alkaloids of *Rauwolfia serpentina*. We are particularly interested in the reported antifertility effects of reserpine in rats[1] and the mechanisms of sedative action[2] of *Rauwolfia serpentina* alkaloids in schizophrenic patients. Reserpine is known[3] to be hydrolysed *in vivo* to methyl reserpate and presumably trimethoxybenzoic acid. The latter compound has been shown[4] to influence certain enzyme systems *in vitro* which are of importance in relation to the mode of action of œstrogens on the uterus. Using a fertility performance test, we have studied the effects of the administration to male and female rats of daily oral doses of 80–100 mgm. of sodium trimethoxybenzoate given over a period of ten weeks. Since no alteration in fertility was observed, we conclude that reserpine itself or some polycyclic metabolite is responsible for the observations of previous workers[1].

We recommend the following paper chromatographic procedures as a means of checking the purity of commercial samples of *Rauwolfia* alkaloids and determining the composition of complex mixtures of the alkaloids used for therapeutic purposes and in pharmacological tests. At the time of writing, we are unaware of any detailed reports on paper chromatography of *Rauwolfia* alkaloids. The methods introduced by us employ Whatman paper No. 542 and the following developing solvent systems:

(1) '*Single phase*' *systems* (no pre-equilibration, capillary ascent technique employed).

(*a*) 10 per cent (v/v) acetic acid in aqueous 5 per cent sodium acetate is shaken with *n*-butyl ether, added in small portions, until saturation of the aqueous phase is just reached. The clear aqueous phase is used.

(*b*), (*c*) and (*d*), similar to (*a*) but using tertiary amyl alcohol, *sec*.-butyl alcohol or methyl*iso*butylketone instead of *n*-butyl ether. (*d*) was particularly useful for slow-moving components in (*a*). Similar solvents have been used previously for urinary phenols and œstriol[5].

(*e*) Xylene 200, methanol 75, methyl*iso*butylketone 25.

(2) *Partition chromatography* (pre-equilibration required).

(*a*) *n*-Amyl alcohol 200, water 180, acetic acid 20.

(*b*) *n*-Hexyl ether 200, methyl*iso*butylketone 50, acetic acid 20, water 180.

Two-dimensional paper chromatography of a commercial concentrate of reserpine and other alkaloids from *Rauwolfia serpentina* revealed twenty-four fluorescent components without using any spray reagents. Suitable combinations of solvents were (2*b*) followed by (1*a*) or (1*b*), or (1*e*) followed by (1*a*).

The following tests may be used for locating the compounds: (i) Fluorescence in ultra-violet light (Wood's glass filter). (ii) Fluorescence after streaking or spotting the paper with 3 per cent sodium nitroprusside in 50 per cent trichloracetic acid (cf. ref. 3). (iii) Fluorescence 30 min. after spotting the paper with microdroplets of 90 per cent sulphuric acid and later spraying with 9 per cent sodium carbonate. Intense blue, green or greenish-blue fluorescent spots are obtained in the alkaloid zones. (iv) Tests (ii) and (iii) followed by spraying with alkaline diazotized I.C.I. 5091 [4]—pink colours. Methyl reserpate and ajmaline are particularly intense. (v) Ehrlich's dimethylaminobenzaldehyde reagent; ajmaline-blue spot which is intensified by the reagent used in (ii). (vi) Bismuth iodide – iodine in ethyl acetate, acetic acid followed by 0·5 per cent sodium dithionite to remove the orange background. Several compounds give salmon-coloured spots; but the sensitivity is not high.

Tests (i) to (iv) are used together as a routine on single chromatograms.

Solvent system (1*a*) gave the best results and tests (ii) and (iii) gave positive reactions with less than 1 μgm. amounts of reserpine and rescinnamine.

The following relative $R_F$ values were obtained using solvent (1*a*): ajmaline 0·76, deserpidine 0·41, methyl reserpate 0·52 principal spot, and 0·76 as well as two other minor components, rauwolscine 0·63, reserpine 0·34, rescinnamine 0·26, serpentine 0·5, yohimbine 0·58, new yohimbine 0·62. With solvent (1*b*) $R_F$ values were: ajmaline 0·75, ajmalicine 0·5, canescine 0·59, corynanthine 0·64, reserpine 0·43, and impurity 0·55, rescinnamine 0·31, and impurity 0·41, serpentine 0·5.

We thank Profs. S. Zuckerman and J. Elkes for their interest and support in these studies. One of us (A. B. K.) is on deputation from the Central Drug Research Institute, Lucknow, India, under the Colombo Plan.

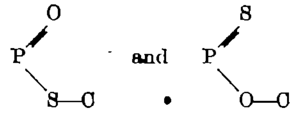
## A General Method for locating the Spot on a Paper Chromatogram of Tertiary Alkyl Phosphates, Thiolophosphates and Thionophosphates

There is no method described in the literat that is generally satisfactory for rendering th compounds visible in paper chromatography. Ha and Isherwood[1] describe a method for phosph amides, for example, 'Schradan'. This method fa with many compounds containing



In the case of 'Systox', about 50 μgm. gives posit results when treated with alkali for a period of to 70 hr.

J. W. Cook[2] reported a new spot test for so organo-phosphorus compounds containing sulph ('Systox' and its isomers). In this method t chromatogram is first treated with N-bromosucci imide and then with fluorescein. The former rea with the sulphur-containing organo-phosphorus co pound. The remaining area of the paper contains fr N-bromosuccinimide which afterwards reacts wi fluorescein, forming a non-fluorescent compoun Exposing the chromatogram to ultra-violet lig renders the organo-phosphorus compound visible a fluorescent spot. Only when the proper amounts N-bromosuccinimide and fluorescein are used is t bromine completely absorbed by the spot, which then located by the fluorescence of fluorescein. T method has therefore the disadvantage that a co trolled amount of bromine and fluorescein has to used. If a quantity of N-bromosuccinimide grea than is needed to brominate the compound is use the excess will brominate the fluorescein as in t background, and thus mask the spot. Similarly, excess of fluorescein will mask the spot throu fluorescence of the background.

If there is more than one spot and the quantities substance in the spots differ, it follows that it impossible to adjust the amounts of reagents to reve them all and give an indication of their concentrati in any one chromatogram.

It was found that all organo-phosphorus compoun containing sulphur so far investigated are, after trea ment with N-bromosuccinimide (dissolved in aceton much easier to hydrolyse. Treatment with ammoniu molybdate solution as used by Hanes and Isherwoo formed blue spots after 10–20 min. exposure ultra-violet light. The method is very sensitiv less than 7 μgm. may be detected as very clea distinct spots. Details of this work will be publish later.

I would like to thank Mr. A. J. Lambie for h help and encouragement and the Directors of Fis Pest Control, Ltd., for permission to publish the results.

## Growth of Pre-Breakdown Ionization Currents in Hydrogen

HE growth of ionization currents with distance onstant low values of $E/p$ ($E$ is the field, $p$ the pressure) at high values of $p$ has been investigated this laboratory primarily to obtain precise de-nimations of the ionization coefficients $\alpha$ and $\omega/\alpha$ conditions, when special attention was paid to state of the gas and cathode surface. Some of results obtained preliminary to the main part his investigation are, however, of general interest. he ionization chamber used was the same as that imilar work with air[1] and nitrogen[2]; the gas was k hydrogen passed through heated palladium and rwards cooled by liquid air. A typical log $I/I_0$ vs. rve ($I$ is the ionization current, $I_0$ the initial current n the cathode, $d$ the gap distance) for $E/p$ = V./cm. mm. mercury and $p$ = 220 mm. mercury hown in Fig. 1, which also gives for comparison rve obtained for hydrogen by Ayres[3] for $E/p$ = 5 V./cm. mm. mercury at the low pressure, $p = 4 \cdot 1$ ı. mercury. It can be shown that both curves ee within the experimental error with the well-wn Townsend relationship :

$$I = I_0 \exp \alpha d/\{1 - \omega/\alpha\,(\exp \alpha d - 1)\}$$

re $\alpha$ is the primary ionization coefficient and $\omega/\alpha$ generalized secondary ionization coefficient. It ows from this result that the mechanism which the criterion for static breakdown in uniform ds is the same at $pd_s \sim 640$ mm. mercury cm. at ressure of 220 mm. mercury as at $pd_s \sim 10$ mm. rcury cm. at a pressure of 4·1 mm. mercury ($d_s$ ng the sparking distance). In this respect the trical properties of hydrogen are similar to those ir and nitrogen.

ther values of $pd_s$ have been investigated and ilar results obtained; these results will be dis-sed elsewhere, since they are concerned mainly h the precision determination of the coefficients l cathode effects. However, since previous asurements[3–5] of $\alpha/p$ were mostly obtained at low pressures and there are considerable discrepancies ween results obtained by different observers, it is interest to give[6] here the preliminary values (maximum error ~ 15 per cent) obtained for $\alpha/p$. These values, obtained for a range of $E/p$ from 16 to 25 V./cm. mm. mercury at a pressure of 150 mm. mercury, are shown in Fig. 2. There is good agreement between these results and the recent results obtained by Rose[6] using modern techniques for the same range of $E/p$ but at low gas pressures. This agreement in values of $\alpha/p$ obtained at the same $E/p$ but widely different gas pressures is direct experimental evidence that the similarity relation $\alpha/p = f(E/p)$ holds for primary ionization over a wide range of pressures from pressures of a few millimetres to 150 mm. mercury in hydrogen. It follows, therefore, that the mechanism of primary ionization is the same over this range of pressures, and implies that the applied field is not substantially distorted in the electron avalanche with the initial current densities ~ $3 \times 10^{-12}$ amp./cm.[2] used.

## Measurements of Retarding Potential on the Hollow Cathode

The hollow cathode[1] consists of a cylindrical closed box of nickel with a small hole at one end. The inner surfaces of the box and the hole are coated with conventional cathode paste.

Various attempts have been made to explain the high current densities (10–100 amp./cm.[2]) which can be obtained from such a cathode; but these cannot be verified until the experimental investigation of the cathode has been completed. In particular, no

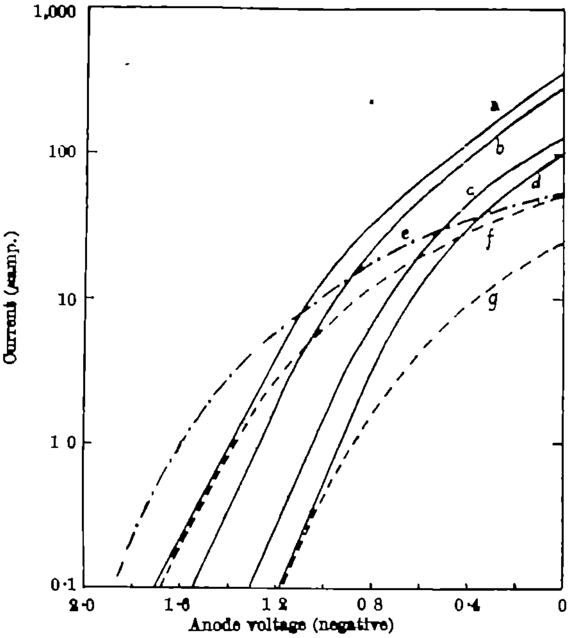

Fig. 1. ———, Hollow cathode: (a) 940° C., (b) 920° C., (c) 865° C., (d) 840° C. – – – –, 'Plug' cathode: (f) 940° C., (g) 840° C. — —, Flat cathode: (e) 940° C.

information was available on the temperature of electrons leaving the cathode, as determined by retarding potential measurements. Such measurements have now been made on hollow cathodes of two types and these have been compared with results obtained with planar diodes.

One type of hollow cathode had an end-wall thickness of 0·75 mm. and a hole diameter of 0·35 mm., and was placed 1·9 mm. away from a plane molybdenum anode. The second type was a 'plug' cathode geometrically similar, but with the hole completely filled with cathode paste instead of being merely coated on its sides. For comparison purposes, some planar diodes were made with a cathode diameter of 4 mm. Typical results are shown in Fig. 1.

It is interesting to compare the curves for the 'plug' and 'hollow' cathodes. The effect of filling the hole in the hollow cathode with cathode paste was to reduce the number of slow electrons emerging from the cathode. The curves tend to merge together as the anode becomes more negative. It was not possible to estimate the electron temperature accurately from the slope of log $I$ plotted against $-V$ because the retarding potential plots did not give the expected straight lines, even with planar cathodes. The electron temperatures calculated from the linear portion of the graph for the hollow cathode were about 1·4 times the values of cathode temperature found from pyrometer and thermocouple measurements. A similar discrepancy was noted in the case of the flat oxide-coated cathode, and this is in agreement with results obtained by Nottingham[2]. He found that the phenomenon was peculiar to oxide-coated cathodes and did not occur with thermionic emission from pure metals.

For low values of anode voltage there was an apparent deficiency in slow electrons for all three types of cathode. It is interesting to note that the effect was more pronounced with the hollow cathode than with the 'plug' cathode. Similar results were obtained with conventional oxide cathodes by Reynolds[3].

The results tend to suggest that the elect temperature of the hollow cathode does not d greatly from that of a normal oxide cathode at same cathode temperature. The explanation of the h current densities observed with positive anode v age does not appear to be due to the property of electron gas inside the box. Tests on the 'plug' cath showed that it was possible to draw anode curre of the same order as those obtained with the hol cathode.

These measurements are indirect support of hypothesis that the greater part of the emiss comes from coating near the edge of the hole.

This communication is published by permiss of the Admiralty.

## Electrophoretic Measurement of the Tru Zeta-Potential of Arsenious Sulphide So in the Region of Slow Coagulation

ACCORDING to Bikerman[1], for "rod-shaped partic with half spherical ends" the true ζ-potential a $\zeta_s$, the potential calculated from the Smoluchow equation, are linked by the following equation

$$\zeta = \zeta_s\left[1 + \frac{2\chi}{(L-r)S}\right]$$

where $\chi$ represents the specific surface conductivity the bulk specific conductivity of the intermicel fluid, $L$ the length and $r$ the radius of the cross-secti of the particle. The equations of Henry[2] and Boo for spherical particles and sufficiently large value the product of the radius of the particle and t reciprocal of the thickness of the electrical dou layer can be expressed in the form

$$\zeta = \zeta_s\left(1 + \frac{\chi}{rS}\right)$$

$$\text{or } \frac{1}{\zeta_s} = \frac{1}{\zeta} + \frac{\chi}{\zeta r S}$$

It follows from equation (3) that under conditio in which $\chi$, $r$ and $\zeta$ remain constant, a plot of 1 against $1/S$ should yield a straight line.

A linear relation between $1/\zeta_s$ and $1/S$ has be observed by Ghosh and co-workers[4-6], when measur by the electro-osmotic method the true ζ-potent of the coagula of colloids in the presence of eq coagulating concentration of electrolytes. The electr phoretic experiments have, therefore, been carri out by us in the presence of equi-coagulating co centration of electrolytes and in the region of ve slow coagulation of the colloid used. The concent tion of the different electrolytes used was so adjust in each case that coagulation of the arsenious sulphi sol occurred between 24 and 25 hr. Burton's $U$-tu apparatus, modified so as to facilitate quick filli with the colloid electrolyte mixture, was used in t experiments. A given volume of the arsenic sulphide sol was mixed with an equal volume of t electrolyte of proper concentration and allowed stand for 30 min. It was next centrifuged for 3 m at a given speed of rotation, the upper portion of t

Table 1

| Electrolyte used | $S \times 10^4$ in mhos | Values of $\zeta_e$ for the movement of boundary | | Average $\zeta_e$ in milli-volts |
|---|---|---|---|---|
| | | Upward | Downward | |
| Cl | 75·60 | 44·32 | 48·48 | 46 4 |
| aCl$_2$ | 8·70 | 23·83 | 26·63 | 25·2 |
| gCl$_2$ | 8·67 | 26·03 | 26·20 | 26 1 |
| lCl$_3$ (containing little HCl) | 6·75 | 31 98 | 32·08 | 32 0 |
| lCl$_3$ (containing less HCl) | 5 59 | 31·07 | 32·22 | 31 6 |
| Cl$_2$ and KCl mixture | 10 53 | 37·16 | 37·20 | 37·2 |
| aCl$_2$ and KCl mixture | 12 27 | 30·42 | 30·60 | 30·5 |
| aCl$_2$ and KCl mixture | 15·10 | 33 05 | 32·25 | 32·7 |

l was separated from the sediment of large particles d the lower part of the $U$-tube was filled with it, e upper part being filled with a solution having e same specific conductivity as that of the inter-icellar fluid of the sol occupying the lower part. e electric current, $i$, flowing through the system ring electrophoresis was carefully measured. om the cross-section of the $U$-tube, the current, $i$, d the specific conductivity of the intermicellar id, the potential gradient was calculated. (In no se did the specific conductivity of the intermicellar uid differ from that of the corresponding colloid–ectrolyte mixture by more than 4 per cent. In the se of potassium chloride the difference was less than per cent.) The results are recorded in Table 1.

From these results it was found that if $1/\zeta_e$ is otted against $1/S$, two straight lines are obtained, e for the mixtures of aluminium chloride with drochloric acid and potassium chloride, and the her for magnesium chloride, barium chloride and ixtures of barium chloride and potassium chloride. hese lines meet the $1/\zeta_e$ axis at two points very ose to each other, giving the average value of $= 49 \pm 1$ mV. The different values of $\chi/\zeta r$ for e two straight lines are therefore to be attributed to e variation of either $\chi$ or $r$, or both, depending on e nature of the electrolytes used. Electro-osmotic ta obtained with negatively charged silver iodide agula[3] indicate that $\chi$ does not depend on the ture of the electrolytes, and we are inclined to tribute the variation of $\chi/\zeta r$ to the change of $r$ only.

The true $\zeta$-potential found for the same arsenious lphide sol under identical concentrations of the ated electrolytes by the electro-endosmotic method 51 mV. The values of the true $\zeta$-potential of arsen-us sulphide particles in the region of slow coagula-on in the presence of equicoagulating concentrations the electrolytes, as measured by the electrophoretic d electro-osmotic methods, are thus in good agree-ent, and their mean is 50 mV. These results, erefore, confirm our previous conclusion that a ven rate of coagulation of a colloid is characterized y a definite value of the $\zeta$-potential independent the valency of the counter ions used.

## Preparation of Aluminium Borohydride and its Applications in Organic Reductions

IT was found that the reaction of aluminium chloride with calcium borohydride[1] in a tetrahydrofuranic solution gives a solution of aluminium borohydride:

$$2AlCl_3 + 3Ca(BH_4)_2 = 2Al(BH_4)_3 + 3CaCl_2.$$

Calcium chloride is precipitated and can be separated by centrifuging in sealed centrifuge tubes; the supernatant contains the tetrahydrofuranic adduct of aluminium borohydride. (By cooling to − 50° this solution gives colourless crystals of this adduct.) Partial evaporation of such a solution at atmospheric pressure gives a residue the aluminium borohydride content of which is considerably greater. Since the boiling point of aluminium borohydride is about 20° lower than that of tetrahydrofurane, this shows that the aluminium borohydride adduct has considerable stability.

The tetrahydrofurane solution of aluminium borohydride is not spontaneously inflammable in air (unlike undiluted $Al(BH_4)_3$), and thus it is relatively safely applicable for reductions of organic compounds.

It is interesting to note that aluminium chloride gives a good yield of the borohydride only with calcium borohydride; under similar conditions (tetrahydrofurane solution) lithium borohydride gives a small yield, while sodium borohydride does not react.

With such solutions (or with solutions of distilled aluminium borohydride[2] in dry tetrahydrofurane) carboxylic acid esters can be reduced selectively to the corresponding primary alcohols. For example, ethyl benzoate and ethyl-$p$-nitrobenzoate are at room temperature reduced to the corresponding carbinols; similarly the aldehydes and ketones, respectively.

Nitriles give the corresponding primary amines: benzyl cyanide and 3,4-dimethoxy benzyl cyanide give primary amines with a yield of about 50–60 per cent.

Nitriles are not reduced with the borohydrides of the alkaline metals; even calcium borohydride—which is a much stronger reducing agent—reduces nitriles only very slowly and with low yields.

Thus the reducing power of the complex borohydrides is lowest in the class of the borohydrides of the alkaline metals (which have a structure of ionic salt character) and highest in the case of aluminium borohydride, which represents a typical covalent structure (boiling point 44° (760 mm.)). The alkaline-earth metal borohydrides represent an intermediate grade in structure as well as in their reducing power.

These correlations between structure and reducing power have, in our opinion, a bearing on the mechanism of such reductions and indeed point to the importance of a molecular reducing mechanism.

*Note added in proof.* After submitting this paper, a communication appeared by H. C. Brown and B. C. Subba Rao (*J. Amer. Chem. Soc.*, 77, 3164; 1955) dealing with applications of a solution of sodium borohydride and aluminium chloride in diethylene glycol-dimethyl-ether for reduction of organic compounds.

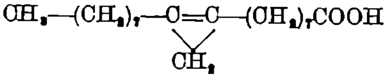
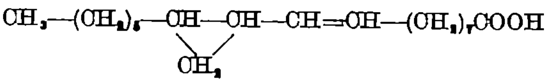
## Structure of Sterculic Acid

In 1952, Nunn[1] put forward a structure for sterculic acid (I), whereas we have assigned to it structure (II)[2]; Dijkstra and Duin[3] have, however, rejected structure (II) on grounds which we believe to be inconsistent with the known facts.



$$\mathrm{CH_3{-}(CH_2)_7{-}\underset{CH_2}{C{=}C}{-}(CH_2)_7COOH}$$

(I)



$$\mathrm{CH_3{-}(CH_2)_5{-}\underset{CH_2}{CH{-}CH}{-}CH{=}CH{-}(CH_2)_7COOH}$$

(II)

(1) Derfer *et al.*[4] have found that the derivatives of *cyclo*propane exhibit an infra-red absorption band in the region 1,000–1,020 cm.$^{-1}$; consequently, they have suggested that a band near 1,010 cm.$^{-1}$ may be used for detecting the presence of a *cyclo*propyl group in a compound.

A *cyclo*propane ring conjugated with a C=C bond (vinyl-*cyclo*propane) has been found by Van Volkenburgh *et al.*[5] to possess a band at 1,010 cm.$^{-1}$. As our value for sterculic acid is 1,004 cm.$^{-1}$ (our revised value[6] being 1,008 cm.$^{-1}$), which is very close to the value of the conjugated compound cited above, a similar type of structure is not unlikely in sterculic acid. Recent work carried out in this laboratory[6] has shown that the bands of the similar *cyclo*propane and *cyclo*propene derivatives prepared synthetically lie almost in the same region, and no analytical value could be set for characterizing a *cyclo*propene group.

(2) Besides cotton seed oil, the Halphen reaction is given by many other seed oils, which according to their reported analyses do not contain even a trace of any fatty acid having a *cyclo*propene group. Further, the exact mechanism of the reaction and nature of the chromogenic substance are not yet settled; possibly some component of the non-saponifiable matter present in the oil is concerned with this colour reaction. In view of this, it is difficult to accept that the reaction is due to the *cyclo*propene grouping alone.

(3) The view that a *cyclo*propane group is less reactive than an ethylene bond is not corroborated in many cases[7]. *Cyclo*propane and its derivatives have been reported[8] to possess appreciable instability and resemble closely the corresponding olefinic compounds in their reaction to heat and some reagents. Thus there does not seem to be any marked fundamental difference between the corresponding derivatives of *cyclo*propane and ethylene, and a *cyclo*propane ring conjugated with a C=C or any other classically unsaturated group behaves very similarly to a typical diene conjugated system[7,9]. It has also been reported[8] that *cyclo*propane and *cyclo*butane are unstable relative to the isomeric alkenes.

On the other hand, the *cyclo*propene derivatives are not so unstable as Dijkstra and Duin[3] have indicated. Their comparative stability and semi-aromatic character were demonstrated by Goss, Ingold and Thorpe[10] so early as 1923. Further, the work carried out in this laboratory[6] on the syntheses of *cyclo*propene compounds has shown that they are fairly stable, so much so that they could be vacuu distilled without decomposition. It may be add that the comparative study of the polymerizati of sterculic acid and 9 : 11-octa-decadienoic acid h not so far been reported, but it is well known th dehydrated castor oil, in which the glyceride of t latter is present to the extent of only 25 per ce gels at ordinary temperature after some time.

Finally, a strong argument against the structu (I) proposed by Nunn[1] is that the compound of th constitution has been synthesized and proved to different from sterculic acid as already reported[2,6].

Dijkstra and Duin[3] have isolated an unkno $C_{18}$-fatty acid from kapok seed oil and assume it contain a *cyclo*propene group, thus leaving a straig chain of 17-carbon atoms (odd number); this unique and merits careful investigation.

The chemical and analytical data giving furth evidence for structure II will shortly be publish elsewhere.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Head (with high academic qualifications and teaching experience together with industrial or research experience in applied mathematics) of the *Department of Mathematics—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (December 7).

River Inspector (preferably Corporate Member of the Royal Institute of Chemistry and the Institute of Sewage Purification), with the Banff, Moray and Nairn River Purification Board—The Clerk to the Board, County Buildings, Elgin (December 8).

Lecturer (Grade II) in Plant Pathology in the Faculty of Agriculture, University College, Ibadan—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1 (December 10).

Lecturers (with M.R.C.V.S.) in (*a*) Bacteriology and (*b*) Biochemistry, in the Faculty of Agriculture, University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1 (December 10).

Lecturer in Geography and Economics—The Principal, Wigan and District Mining and Technical College, Wigan (December 12).

Lecturer in Mathematics at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 12).

Junior Research Fellow, and a Senior Research Fellow (physicists or physical chemists) in the Department of Glass Technology—The Registrar, The University, Sheffield (December 15).

Nuffield Research Fellow at the Wheatstone Physics Laboratory, to work on the physical chemistry of fibrous proteins—Prof. J. T. Randall, F.R.S., Department of Physics, King's College, Strand, London, W.C.2 (December 15).

Assistant Lecturer in the Department of Applied Mathematics—The Registrar, University College of Wales, Aberystwyth (December 16).

HEAD (with high academic qualifications, preferably an honours degree in mining, practical mining experience and teaching experience) OF THE MINING AND GEOLOGY DEPARTMENT—The Principal, Wigan and District Mining and Technical College, Wigan (December 19).

LECTURER (graduate in science or technology and preferably with experience of reinforced concrete design) IN STRUCTURAL ENGINEERING—The Registrar, College of Technology, Manchester 1 (December 19).

LECTURER IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Manchester 13 (December 19).

CHEMIST, Senior Research Officer or Principal Research Officer grade (with a good honours degree in chemistry, with postgraduate research experience in the fields of inorganic or physical chemistry), with the Australian Atomic Energy Commission, to undertake research in the chemistry of reactor materials including their behaviour under conditions of high temperature irradiation—The Secretary, Australian Atomic Energy Commission, G.P.O. Box 5343, Sydney, Australia (December 31).

DEMONSTRATOR (with a good honours degree in physiology, biochemistry or chemistry, with subsidiary physiology, or medically qualified) IN CHEMICAL PHYSIOLOGY—The Registrar, The University, Manchester 13 (December 31).

HEAD (with high academic qualifications and teaching experience together with industrial or research experience in applied physics) OF THE DEPARTMENT OF PHYSICS—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (December 31).

PHYSICIST, Principal Research Officer grade (with a good honours degree in physics, plus at least ten years research experience), with the Australian Atomic Energy Commission, to work in the field of reactor physics embracing such aspects as exponential and zero energy experiments and criticality and kinetic studies—The Secretary, Australian Atomic Energy Commission, G.P.O. Box 5343, Sydney, Australia (December 31).

PLANT PHYSIOLOGIST, STATISTICIAN (Biometrician), and an ASSISTANT ENTOMOLOGIST in the Wattle Research Institute of the University of Natal, Pietermaritzburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, December 31).

SENIOR LECTURER IN THE DEPARTMENT OF MECHANICAL ENGINEERING at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (January 6).

READER IN MECHANICAL ENGINEERING at King's College, London, W.C.2—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 10).

READER IN METALLURGY at King's College, London, W.C 2—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 12).

LECTURER OR ASSISTANT LECTURER IN METALLURGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, January 15).

CHAIR OF CIVIL ENGINEERING at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 18).

CHAIR OF BIOCHEMISTRY at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 19).

READER IN PHYSIOLOGY at London Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 26).

READER OR SENIOR LECTURER IN THE THEORY OF COMPUTING in the Department of Mathematics—The Registrar, The University, Manchester 13 (January 31).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (2) IN PHYSICS, CHEMISTRY, METALLURGY, ENGINEERING OR GEOLOGY, or in a subject allied to these—The Registrar, University of Wales, University Registry, Cathays Park, Cardiff (March 31).

ANALYTICAL CHEMIST, Experimental Officer grade (preferably with a pass degree in chemistry, or at least H.N.C. (science) or equivalent, several years experience in a research or inspection laboratory, and a sound knowledge of basic analytical methods), for research and development work in an analytical laboratory—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting A.629/34.

ENGINEER (with a first- or second-class honours degree or equivalent in engineering, and good mathematical ability) IN THE STRUCTURES DIVISION of the Royal Aircraft Establishment, Farnborough, Hants, for duties which involve planning and execution of instrumented flight trials and analysis of results of such tests—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.527/5A.

EXPERIMENTAL OFFICER OR ASSISTANT EXPERIMENTAL OFFICER (with considerable experience of the breeding and management of rabbits, rats, mice, etc., for experimental work) to take charge of the Small Animal Department—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

EXPERIMENTAL OFFICER (with at least H S.C. in science subjects, or equivalent qualifications) IN THE CHEMICAL ENGINEERING DIVISION, for work in a cryogenic laboratory engaged on the operation of liquid hydrogen plant and the construction and operation of experimental low temperature equipment—The Establishment Officer, U.K. Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 453.

LECTURER IN THE DEPARTMENT OF ELECTRICAL ENGINEERING at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

LECTURER OR ASSISTANT PROFESSOR IN PURE MATHEMATICS, and a LECTURER OR ASSISTANT PROFESSOR IN APPLIED MATHEMATICS—Prof. I. R. Pounder, The University, Toronto.

LECTURERS (with a good honours degree and industrial experience) IN (*a*) HEAT ENGINES, and (*b*) FLUID MECHANICS, in the Department of Civil and Mechanical Engineering—The Secretary, Royal Technical College, Glasgow.

PHYSICISTS, to assist in physical and clinical work associated with X-ray and isotope treatment and investigation—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W 3.

RESEARCH FELLOW IN ANIMAL ECOLOGY for research in the ec
of the insects and mites associated with pastures in the wheat
of South Australia—The Registrar, University of Adelaide, Ade
South Australia.

SENIOR LECTURER (with a good honours degree, together
teaching experience, and preferably with industrial and/or res
experience) IN INORGANIC CHEMISTRY, in the Department of Chem
and Biology, College of Technology, Liverpool—The Direct
Education, 14 Sir Thomas Street, Liverpool 1.

# HIGHER TECHNOLOGICAL EDUCATION IN BRITAIN

LTHOUGH in his inaugural address as rector of the Imperial College of Science and Technology October 11, Dr. R. P. Linstead made no fresh tement as to the building plans for the College, he l enough about the future of the Imperial College indicate the shape that this new development in her technological education is likely to take. Some the implications can now be seen fairly clearly, l it is important that they should be fully dis- sed, and appropriate measures taken elsewhere counteract any possible weaknesses which this iely new but desirable experiment in techno- ical education may involve in the system of higher hnological education in Britain. Dr. Linstead's lress establishes beyond question that the expan- n of the Imperial College is being planned to make major contribution to the supply of technologists the postgraduate level, and that it is doing so in ys for which there is no precedent in the univer- es of Britain or in institutions such as the Massa- setts Institute of Technology in the United States elsewhere.

In his presidential address to the North-Western anch of the Science Masters' Association a year o, Dr. B. V. Bowden described the American titutes of technology as essentially universities, ling in the main with practical subjects, with nanities as subsidiaries ; and he added that one of ir aims was to produce large numbers of cultured lified men who at the same time are essentially ctical rather than theoretical in outlook. That is air description of the type of men and women ich the Imperial College hopes to produce in reasing numbers ; but, as Dr. Linstead indicated, s hoped to do so without including the humanities cifically in the curriculum.

Since some of the American institutes of tech- ogy require their students to spend 16–20 per t of their time on the humanities, the expansion the Imperial College to what may fairly be cribed as a technological university with some 00 students—with about 1,400 of them post- duates—and an administrative and teaching staff 1,500, comparable in size roughly with the Univer- es of Birmingham, Leeds or Liverpool, may be cribed as a new venture in respect both of structure l of curriculum. The scientist and technologist l have unfettered and unchallenged opportunity demonstrate the capacity of their disciplines to elop men capable not only of clear thinking but o of a balanced outlook, and imaginatively alive the human issues with which the technologist, less than the manager and administrator, is fronted.

Dr. Linstead was re-assuring on two or three nts. He does not think that the proposed expan- n will be achieved at the expense of other versities or of the technical colleges. Although ost the whole of the undergraduate students of the College come from within the United Kingdom, it is probable that the additional intake of about one hundred freshmen a year will come from the impending bulge in the senior school population, quite apart from attention to such measures as have been suggested in the report on "Early Leaving" and elsewhere. Moreover, the extent to which postgraduate students are drawn from overseas suggests that the prospects of obtaining the greater numbers of students of high quality is reasonable enough, in spite of the misgivings which Sir Henry Tizard expressed in his Haldane Memorial Lecture. Further, as Dr. Linstead pointed out, a considerable proportion of the postgraduate students will come from posts in industry or government service, and from other universities and colleges.

Concentration of such advanced specialized technological training is clearly desirable from the national point of view, and Dr. Linstead indicated that the Imperial College recognizes its responsibility for choosing its regions of specialization wisely in relation to national needs and the provisions made elsewhere. He also forestalled criticism in his remarks as to the reduction of wastage. This occurs in all universities, though not always at the same stage. At the Imperial College it occurs mainly at the end of the first year, where it is obviously better to effect any necessary elimination rather than later. None the less, attention is being given to the further reduction of this wastage. some of which is certainly unavoidable if high standards are to be maintained.

On these and other points it must be some years after the end of the next quinquennium before any sound judgment can be formed as to the value of this experiment, or as to its full implications for the expansion or development of technological and technical education in Britain. Meanwhile, it should be recognized for what it is—a massive experiment in education that is in line with much that has been in progress elsewhere in the universities since the Second World War and of which the University College of North Staffordshire provides a striking example. It is also thoroughly in keeping with the British genius for improvization and experiment, to which we already owe important advances, and which incidentally provides one of the fundamental reasons why a system of education is not exportable.

Perhaps the feature of this expansion which will be watched with the closest interest is the success of the attempt to provide a broader education, and by novel methods to produce technologists and scientists of the highest professional competence who are also well-educated men and women competent, in Milton's phrase, "to perform justly, skilfully, and magnanimously all the offices both private and public of peace and war" that may fall to their lot. The interest will indeed be the keener in that here the Imperial College has not yet fully determined in detail the methods it means to use. Indeed, as Dr.

Linstead pointed out, some of the most important broadening influences cannot come into play on any adequate scale until the building plans have advanced.

Prominent among these are the plans to increase the residential accommodation from its present eight per cent to sixteen (about five hundred residents) and to provide a new Students' Union double the size of the old. This expansion is viewed as part of a deliberate attempt to encourage the broadening influence of informal discussion between students outside their formal studies, and to provide conditions in which the programmes of general studies and week-end discussions can most favourably take place. Dr. Linstead stressed the importance of all such efforts the more in that he recognized that there are strict limits to what can be attempted within the normal curricula. He also referred to the broadening influence of the great flood of London life as something unrivalled in more provincial environments.

While the possibility of such an extra-curricular education will be granted, Dr. Linstead may well be optimistic as to its probability, even under due guidance and encouragement. Some inquiry on this point might well be worth while. What he said as to keeping the range of studies natural and appropriate to the College as wide as possible, should also be noted. The full range of subjects appropriate to a university will not be achieved at South Kensington; but on the teaching and practice of the departments of pure science will largely depend the success of this attempt to provide, not narrow technologists, but educated men capable of vision and sound judgment. Unless those departments rise to the challenge and show that their disciplines can be taught with imagination and balance, the experiment will be in grave danger.

Clearly, much will depend on the extent to which the departments of pure science are kept strong and of the highest standard, and on the quality of the staff; though it is probably also true that in respect of some of the other broadening influences mentioned by Dr. Linstead the quality of the students will have some influence in determining their effectiveness. This is notably true in respect of life in London, which presupposes a certain stability of character if it is to be beneficial, and also no undue pressure of home influence or poverty. At best, in fact, while a modicum of hostels and a good Students' Union make the social life of the College warm, their broadening influence is random.

Nor is the mastery of and delight in the Queen's English, which Dr. Linstead also commends, to be achieved without systematic and deliberate effort. Particularly if it is to assist the graduate to carry away from such an institution an awareness of the richness and diversity of life and an appreciation of those things which adorn it, more is likely to depend on the teaching in the schools than on that given at the Imperial College in a curriculum from which non-scientific subjects are excluded. The Imperial College under such conditions can do little to further this end, except perhaps by developing as early as possible, and perhaps expanding, the experiment of an optional preliminary year to which Dr. Linstead referred. The non-scientists entering under suc scholarship scheme could well provide a very effec leaven under the conditions which increased r dential facilities and the new Students' Union provide.

An even more promising and less-random influe could be the teaching of the history of science technology, a general knowledge of which would Dr. Linstead said, give a sense of perspective balance, and show something of the way in wh great minds have urged men forward. It is a li disappointing that Dr. Linstead did not give evidence that the Imperial College proposes experiment in this field, as has been done elsewh in recent years. Cambridge scientists, for exam are almost unanimously in favour of teaching history and philosophy of science, and under History of Science Committee set up in 1947 th courses have been tried to spread such teaching. proportion of scientists reading the history philosophy of science is now about one in ten, an diploma in the subject is at present under conside tion and, alternatively, a proposal to make it subject for Part II of the Natural Sciences Tripos even a separate Tripos.

Another such experiment, in the more limited fi of engineering history, at King's College, Univers of Durham, was described by Prof. A. F. Burstall the summer meeting of the Newcomen Society June. Here, however, the primary objectives w to teach the students to read critically and to courage them to acquire sufficient broad fact knowledge of the history of technology to deve the breadth of vision claimed as characteristic students of history. It was also desired to encour them to work together, and in a measure to le from one another in just the way in which Linstead visualizes the students at the Impe College may acquire a broader outlook.

Whether or not the decision to extend the fi degree course from three years to four years is tak a strong case can thus be argued for including history of science and technology in the be curriculum. Its exclusion could only be justified the face of clear evidence that sustained and w planned, rather than random, efforts are being m to encourage the development of a broad outlo and wide appreciation of cultural values and hum achievement. Dr. Linstead and his colleagues sho be alert to see that neither any promising experim of this kind nor the scholarship experiment for n scientists to which he referred is allowed to hamstrung or limited by unreasonable examinat requirements.

The study of English, however, has a further, equally important, aspect for the student of scie or technology on which Dr. Linstead did not tou though it was the subject of a lively discussion l month before the Parliamentary and Scientific Co mittee, in which the Duke of Edinburgh took pa

Mastery of the English language is desirable fr the point of view of the communication of ide quite as much as from that of encouraging a scie of perspective and balance. Whatever point of vi take with regard to the interpretation of science, ether we lay the onus on the scientist for expressing aself in terms and in ways that the layman can lerstand, or whether, like the Duke of Edinburgh l Sir Henry Tizard, we look rather to the improve- nt of the scientific education of the layman, with- a reasonable mastery of English the scientist is likely to be able to communicate fully even with se in other scientific fields. It is not simply a tter of avoiding unreasonable demands on the entist to express himself in non-technical language; less his choice of technical terms is restrained the sense of perspective and balance which an equate knowledge of his mother-tongue confers, no provement in the technical and scientific know- ge of the ordinary citizen will avoid confusion and sunderstanding. Mr. Ritchie Calder has quite htly insisted that the communication of knowledge d ideas depends fundamentally on the careful and lful handling of words, and this is as true of scientific or technical paper as of popular position.

The success of this experiment at the Imperial llege of Science and Technology will really depend two things: first, whether the College can secure d maintain a teaching staff of the requisite standard d breadth of vision, capable, within the limits set the scientific and technological disciplines to be ght, of inspiring their students with that same eadth of vision and understanding, no less than th the capacity for clear and critical thinking. condly, it will depend no less on a continuing entry students of sufficient capacity. Any relaxation of ndards in either respect—in the recruitment of ff, or the selection and elimination of students— uld be fatal. For that reason alone, the progress the experiment should be closely watched, and rticularly carefully by the University Grants Com- ttee and the Parliamentary and Scientific Com- ttee. For although the recent broadsheet on raduates' Jobs" issued by Political and Economic nning is only a preliminary survey, it gives at st a hint, which is supported elsewhere, that there a strict limit to the number of students qualified to fit by courses such as an institution of the standard the Imperial College provides. Part of the solution Britain's problem of scientific and technical man- wer lies in the wiser and more efficient use of the ited supply of really first-class minds.

# PURPOSE IN EDUCATION

ucation and the Modern Mind

Prof. W. R. Niblett. Pp. 155. (London: Faber d Faber, Ltd., 1954.) 8s. 6d. net.

MANY books are published dealing with educational topics; surprisingly few are written out education itself. Prof. W. R. Niblett has empted to do this, and by all except the con- ned materialist, his book will be welcomed both its inspirational qualities and for its practical ggestions on means of achieving ends which are mittedly difficult to attain.

Throughout the book Prof. Niblett emphasizes that it is no good considering the purpose of education without discussing the purpose of living itself; it is impossible to evolve a satisfactory philosophy of education without having evolved a satisfactory philosophy for life. Unfortunately, so many people in the Western world assume that the reason for existence is to 'get on' and be 'happy'. This superficial attitude to life has bitten deep in many people and seems to be an accompaniment to the mentality associated with the Welfare State.

Prof. Niblett questions whether the acquisitive attitude can provide a satisfactory philosophy of life, since it leaves out a whole dimension of human experience; it is very doubtful whether it leads to 'happiness'. Much of the so-called 'happiness' to-day is there only when there is something 'going on'; too often this is succeeded by a vacuum of despair when people come face to face with themselves.

There are signs, however, that the determination to 'get on' is failing to satisfy and that the possession of material resources may be temporarily satisfying but fail to satisfy those fundamental requirements of man which are of an intangible nature. As a result, a new challenge is being presented to all who help to educate the young. Some educationists respond to this challenge by seeking to increase the number of schools and laboratories and community centres. Others, and Prof. Niblett is one, believe that these things are desirable only if they are used to extend and strengthen fundamental values and that much more could be done with existing facilities.

Fundamental values, he says, have been weakened by two main causes—one minor and one major: the minor cause is two World Wars; the major, the spread of the scientific temper of mind. As an instrument of analysis, the latter is indispensable, and there is need for its wider extension throughout the world if, as is desirable, more and more people are to benefit from material progress. Yet extension carries certain dangers. The application of scientific disciplines like psychology and sociology to problems of man himself leads many to believe that all man's experience is amenable to detached analysis. At this point Prof. Niblett stands firm and, in words of rare poignancy, argues with conviction that there is much in human experience which no known methods of analysis can explore. There are different kinds of facts, different kinds of knowledge, and different kinds of human experience. Some of these can be acquired by direct 'education'; some by providing the right kind of environment, inside or outside the schools. Others can only be arrived at by living itself and by the transmission of standards and values from one person and one group to others.

In the latter part of his book Prof. Niblett suggests ways in which educational institutions can effectively pass on the basic requirements for living like the three 'r's' as well as the basic requirements for life like analytic detachment, humour, humility, responsibility, sympathy, unselfishness and courage. Here some educationists will quarrel with his choice of subjects and the suggested methods of treatment. Few will withhold their respect for views which bear the hall-mark of original thought and which do not regard long-established curricula as sacrosanct or immutable. With many children, for example, Prof. Niblett thinks that much time is wasted in trying to teach them arithmetic despite years of failure; why, for such children, should it not be dropped at, say, fourteen years of age? Much valuable time could also be saved if a bolder policy of omission were carried out in all kinds of schools with foreign languages and subjects like drawing and woodwork.

Many sixth-form science teachers will feel that Prof. Niblett's strictures on the teaching of science in grammar schools are a little harsh. Yet most will agree that there is the ever-present danger that, to many sixth-form boys, "his science, instead of being a discipline, becomes an end, itself degenerated to a technique, a know-how of getting through examinations and later a know-how of technical progresses, and not the beginnings of a philosophy". Science can, and should, be taught to nourish the imagination and to add to the power to generalize. With teachers who possess both a philosophy of science and a wide scientific knowledge, it is not too difficult for students to catch the meaning and method of scientific inquiry and the humility which goes with it.

The final chapter is concerned with the release of leadership. The value of tradition in the life of the school is well brought out—as is the difficulty of building one in many secondary modern schools which are too tightly controlled by local education authorities. If ground is to be prepared, however, in which leaders may grow, there must be a constant succession of teachers of high quality—men and women whose own lives reflect the most worthy characteristics of a good society. Does our society want such a flow of teachers? What status have they in the community? What salaries are they paid? How many teachers are asked to serve on representative national committees—even committees upon education itself? How many teachers ever appear in New Year or Birthday Honours lists?

These are questions which a good society would be able to answer in a way that would recognize the importance of the teaching profession at all levels to the community as a whole. They have been sharply pointed by an author who has thought deep and writes with such skill and lucidity that his book deserves to become as well known as Sir Richard Livingstone's "The Future in Education".

# TEXT-BOOKS OF NUCLEAR PHYSICS

### Nuclear Physics

By Dr. Irving Kaplan. (Addison-Wesley Series in Nuclear Science and Engineering.) Pp. xi+609. (Cambridge, Mass.: Addison-Wesley Publishing Company, Inc., 1955.) 10 dollars.

### Nuclear Physics

By Prof. Alex E. S. Green. (International Series in Pure and Applied Physics.) Pp. xv+535. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 64s. 6d.

IN the first of these two books under review, Dr. Irving Kaplan requires no more of his reader than "a two year course in college physics and a familiarity with integral and differential calculus". From such small beginnings he has produced a thoroughly readable and clear account of most features of 'pure' nuclear physics, and found room for such items of 'nuclear technology' as the design of accelerators, nuclear reactors and isotope separation.

In the first quarter of the book the nucleus is approached no more closely than Rutherford's early researches on α-particle scattering allowed. T starting-point is the earliest chemical evidence for atomic theory and a periodic table of elements. T classical experiments on cathode and 'canal-rays' described next, and the discovery of radioactiv and elementary methods of radiation detect follow. Particularly well treated is the derivation the Rutherford scattering law and its verification. which the original experimental results confirm the predicted dependence on the element, α-particle energy, the angle of scattering and thickness are tabulated. An account of Mosele work on X-rays is followed by chapters on quantum theory of radiation, the special theory relativity and the Compton effect, and the hydro spectrum and its interpretation with the Bohr mo The hybrid nature of this model receives pro emphasis; the introduction of wave mechan completes the first part. A plausible derivation Schrödinger's equation is included, without a examples of its solution; the interpretation of periodic table in terms of the electron configurat and the operation of the Pauli exclusion princi are particularly clear.

The second part of the book, approximately o half of the total, is concerned with the nucleus prop The difficulties of the 'electron proton' model for nucleus and its replacement by the 'neutron prot model, the magnetic and electric moments, statist and parity are dealt with first. The accurate deter ination of nuclear masses is described; but interpretation is left to later chapters. Chapters foll on the laws of radioactive decay, with tables of natural radioactive series, on the types of nucl disintegration which may be produced by accelerat particles, on artificial radioactivity and on the det of the interactions with matter and the spectra α-, β- and γ-radiations. At this point, there is return to nuclear reactions, the discussion conc trating on the nuclear physics, rather than nucl chemistry as earlier. The approach is descript throughout, and the experimental methods, resu and interpretations are kept closely together. T classification of reactions follows that of Blatt a Weisskopf; reactions in the lighter nuclei are de with in a separate section and the emphasis in t field on the details of nuclear energy-levels, rat than the reaction mechanisms, is well brought o The second part of the book closes with a chapter nuclear forces and nuclear structure. The summa of results on the interaction of two nucleons perhaps condensed too much, but the evidence for magic numbers is well set out. The descriptions the shell model, and Bohr's collective model, are v short indeed, and there is no account of the 'clou crystal ball'.

The third part of the book, approximately o quarter, deals with special topics and applicatio 'Neutron physics' is concerned mainly with t detection of neutrons, diffusion and slowing dov and the measurement of the various cross-sections different energy regions, with little interpretation results. The remaining chapters are devoted fission, nuclear reactors, accelerators and isoto separation.

The main general impression is that the book extremely readable. The line of development neither strictly historical, nor by subject-mat (certain topics are discussed several times in wid separated sections), but is always clear. All releva major review articles together with many referen the literature are listed at the end of each chapter. list of problems is also given; these are elementary d do not require access to material outside the ok. Illustrations are excellent and copious, and a ge chart of nuclides is included.

The book will be ideal for those whose work in ighbouring fields (reactor engineering and radio-emistry, for example) brings them in close contact th nuclear physics, and for many physics students. r undergraduates intending to specialize in this ld and research students the book will be valuable, t a greater theoretical background will have to be ught elsewhere. No serious inaccuracies were noted. ie text and diagram illustrating the energy-levels the hydrogen atom are in disagreement; the mark that a smaller magnet is required in a linear celerator than in a circular machine producing rticles of the same energy is either self-evident or o subtle for the general reader.

The second book, by Prof. A. E. S. Green, also mmences with a review of atomic physics. This is tremely compressed and requires that the reader ow the field, well beforehand. The next chapter umerates the static properties of nuclei—the radii, asses and moments—and includes a long section on e classical interactions of the various moments with field. The next three chapters are devoted entirely technology and deal with accelerators, 'precision struments' and detectors. It appears that much of e material contained herein would have been better aced in an appendix; an extremely complicated awing of a β-ray spectrometer, circuit diagrams of nplifiers and multichannel pulse-height analysers, d a diagram illustrating how to read the inter-lating lights of a scale-of-eight counter do not seem propriate at this stage. More general ideas on how e various instruments are used for elucidating decay hemes or reaction constants are not put forward lequately. Chapters follow on radioactivity and iclear reactions. The latter includes a detailed dis-ssion on the absorption of γ-radiation and a com-ete treatment of the classical mechanics of reactions d the transformation between laboratory and ntre of mass co-ordinates. The next chapter, on stematics and tendencies of nuclei, is a very orough investigation of the nuclear energy surface a function of atomic and mass numbers (and en–odd properties) and includes a discussion of the egularities at the magic numbers. In the following apter the liquid drop model is presented, and the terpretation and best values of the parameters in semi-empirical mass formula are discussed at igth; the chapter ends with a discussion of fission d the achievement of a chain reaction. The chapter quantum mechanics and the nucleus is an excel-it presentation of the Schrodinger equation; a riety of applications follows—to single bodies in rious wells and to two- and many-body problems. ie discussion includes the time-dependent wave uation, perturbation theory and the coupling of gular momenta. The next chapter discusses various iclear models in fair detail, mainly in relation to ound-state properties. That on nuclear decay vers γ-, β- and α-ray decay theory concisely and arly. The formal theory of reaction processes is veloped next, and this is perhaps the most valuable apter in the book, which closes with an analysis of iat is known of nuclear forces from the low-energy cleon–nucleon interactions and the properties of the iteron, the difficulties raised by high-energy results, d a brief excursion into meson field theory.

Reference lists are given with each chapter, together with problems graded in difficulty, some requiring extensive reference to the current literature.

The book is in many ways complementary to that by Dr. Kaplan. A previous study of the latter will help overcome the difficulties arising from the rather complete separation of techniques, results and interpretation made by Prof. Green. His book, on the other hand, though requiring more from the student and covering less ground, is able to provide the necessary discussion of the more difficult topics treated in a purely descriptive fashion by Dr. Kaplan. A few errors have been noted. The very brief description of deuteron stripping suffers from confusion between the appearance of groups of product particles of discrete energies and resonance in the reaction yield. In the discussion of neutron-detection techniques, the use of a chamber filled with boron trifluoride is described, and the statement is made that "these chambers may be used as proportional counters in the low-energy region, since the reaction yield for a fixed neutron flux depends sensitively on the neutron energy". This is a novel and unhelpful usage of the term "proportional counter". The derivation of the reciprocity theorem needs more explanation, and spin factors might well have been included.

# ELECTRICITY FOR THE UNINITIATED

### A Guidebook to Electricity

By J. H. M. Sykes. Pp. 275+16 plates. (London: Hutchinson's Scientific and Technical Publications, 1955.) 21*s*. net.

Writers of popular science books might well study the handicapping system used in golf. The real expert does not moderate his accuracy to suit the competence of his companion; instead, an approximate adjustment to equal terms is made on a quantitative rather than a qualitative basis, and the full rigour of the game is enforced. If similar measures had been taken by the author of this well-illustrated and informative book, by simply omitting paragraphs here and there, one could recommend it without reservation or criticism.

The descriptions of electrical machines, wiring systems, domestic appliances and communications devices are good, and the technical side is well presented in an interesting manner. Alternating current in general, and three-phase systems in particular, are discussed very clearly in non-mathematical terms; and there are a glossary and some useful tables at the end. The general reader for whom it is primarily intended will gain from it a good idea of the way in which most of the applications of electricity in everyday life work. This, according to the preface, is the limit of the author's aim, and in this he has succeeded.

Bearing this deliberate limitation in mind, any criticism of the references to fundamental principles may seem unfair. But it is one thing to avoid delicate discussion of the facts of life, and quite a different matter to describe stork-legends seriously and in circumstantial detail. That the liberation of an electron from a copper atom "could only be undertaken if enormous force is available, such as the power necessary when nuclear fission is carried out", and that "the speed with which electrons fly round their orbits in each atom is related to the temperature—if the temperature is greatly increased they begin to fly round so rapidly that eventually one of them flies off altogether by a kind of centrifugal force" are statements in a class by themselves. The introduction to radio as the propagation of "electromagnetic and electrostatic" waves by a process of electrostatic induction is unfortunately plausible. The old international ohm is defined as a piece of platinum preserved somewhere, and even the statement of Ohm's law would not be accepted in an Ordinary-level physics examination. The unwritten law (which should be restricted to the same category of book) requiring a certain tempering of the scientific usage of the terms force, work, and power for the layman, so that they are used correctly in some places and interchangeably in others, has been operative here.

The pity is that blemishes of this kind in an attractive and otherwise excellent book should, because they are barely relevant to its main message to the general reader, appear to be trivial. They greatly reduce its value for the student to whom it is also directed, for he cannot afford to take that point of view. In guide-book terms, this does the tourist handsomely and treats the fell-walker pretty well; but it is not for those who also want a little serious climbing.

G. R. NOAKES

# PROBLEMS OF TECHNICAL LIBRARY SERVICES IN GREAT BRITAIN

## Commercial and Technical Libraries

By J. P. Lamb. (The Library Association Series of Library Manuals—10.) Pp. 316+7 plates. (London: George Allen and Unwin, Ltd., and the Library Association, 1955.) 21*s*. net.

THE Sheffield City Librarian, Mr. J. P. Lamb, has long been known outside the circle of public librarians for his part in the highly successful interchange scheme for technical publications which he first described to an Aslib Conference more than twenty years ago. This latest book of his is addressed primarily to those concerned with the running of a public commercial and technical library. While, however, his chapters on the equipment and staffing of such a library, the principles which should determine its relation to the public library system generally or the selection of its stock, whether of books and periodicals or of patent specifications, are chiefly of interest to those engaged in such work, the imagination and shrewd common sense which have contributed so much to the success of the Sheffield scheme continually break through and give his chapters a wider interest or relevance. Always he is impatient of operational ineptitude or of grandiose schemes which have little relation to reality, whether it be for book coverage or anything else. He is keenly alive to the fact that libraries are for use, and this pervading sense of users' needs makes such a chapter as that on organization and administration as interesting to the general reader as to the librarian.

To the technical librarian in industry these chapters are almost as useful and suggestive as they are to the librarian engaged in public library service, and parts of them will interest the technologist and scientist. To such, and perhaps to the industrialist generally, the chapter on external activities will of no less interest, and many will be surprised at t scope and extent of the activities of the technic information departments which are already mai tained by some public libraries. Mr. Lamb's accou is the more welcome in that, as he duly points o an inquiry in this field made by the Federation British Industries, in collaboration with the Panel Technical Information Services of the Committee Industrial Productivity, largely overlooked what w being done by the public libraries and gave indication of the extent to which such activiti enable commercial and industrial concerns economize in the information services they the selves maintain.

In Great Britain the smaller firms especially are yet barely conscious of the needs which the publ commercial or technical library could thus meet, a Mr. Lamb is rightly critical of this omission in important report, the paragraphs of which relati specifically to public libraries he quotes in full in h final chapter. It is this chapter and that in whi he reviews briefly the history of British commerci and technical libraries and notes some of the miss opportunities of the inter-war years that are of mo interest to the general reader as well as to t scientist. To the latter this concluding chapter, wi its admirably balanced survey of the future in whi proposals, for example, for a science centre, includi a national lending library of science and technolog as well as a national reference library for that fiel are placed in their proper perspective in relation the existing library resources of Britain, includi those of the public library system, is absorbing.

This chapter, which displays clearly the bearing an efficient technical library system on technic education, industrial research and industrial efficienc in general, is of particular interest at the moment i that, since this book was written, the Advisor Council on Scientific Policy, in its eighth annu report, reverts again to the place of scientific librari in the national economy, both in securing the mo effective use of the nation's scientific and technic man-power and in furthering the dissemination technical information as well as the development higher technological education. In this respect M Lamb's account needs amplifying, for as it stands suggests that the Advisory Council has dropped i support for the project of a national lending librar For all that, his chapter admirably states the ca for a national lending library and a national referenc library and for the way in which both could be su ported by existing public technical library service It gives a concise but clear picture of the advantage and economy to be derived from a carefully though out policy of utilizing to the full existing service but providing at the centre the essential nation services to which the Advisory Council on Scientifi Policy points.

The limitations of interchange schemes are clear recognized; but none the less, Mr. Lamb puts clear and fairly both the advantages of such schemes i relieving pressure on a national lending library science and technology and the case for a governme grant to those public technical libraries which, b co-operating in this and other ways with the nation lending reference library, would increase its efficienc and resources and secure a better use of the nation' existing resources and services, whether in the wa of books and periodicals or of trained staff.

R. BRIGHTMAN

## itish Journal of Applied Physics

dited by Dr. H. R. Lang. Vol. 5, 1954, and pplement No. 3: The Physics of Particle Size nalysis—a Conference arranged by the Institute of hysics and held in the University of Nottingham om the 6 to 9 April, 1954. Pp. vi+466+supple- ent 218. (London: Institute of Physics, 1954.) 14*s*. 6*d*.

N its annual report to the board of the Institute of Physics, the advisory committee of the *British ournal of Applied Physics* recently commented on e satisfactory increased circulation and high andard of the *Journal*, and this is amply justified y Vol. 5 which covers 1954. The volume contains welve special articles, three conference reports and venty-nine original contributions, in addition to a ngthy supplement of 218 pages.

Most of the special articles consist of lectures elivered by their authors to various branch and roup meetings of the Institute. R. W. G. Wyckoff rites on the growth of X-ray diffraction work in e United States—the subject of his evening discourse the X-ray Analysis Group on November 20, 1953; V. A. Wooster on diffuse X-ray scattering and the hysical properties of crystals; O. R. Frisch on the eginnings of atomic energy, and R. Fürth on statis- cal concepts in theoretical physics, both lectures to he Education Group; V. Daniel on the thermo- ynamic approach to solid structure; and others on uch varied topics as supersonic gas flow, the elec- rical breakdown of gases, the junction transistor, and he near infra-red absorption spectra of fibres. In he three conference reports, the proceedings are ummarized of the conferences on X-ray analysis held n London during November 1953 and in Cambridge uring April 1954, and on electron microscopy in ondon during November 1953.

The secretary of the Institute of Physics and editor f the Institute's journals, Dr. H. R. Lang, contri- utes the editorial note to the supplement, which is record of the proceedings of the conference on the hysics of the analysis of particle size, arranged by he Institute and held at the University of Notting- am during April 6–9, 1954. Forty-two papers were resented, and these, together with the discussions n them, are grouped in eight sections corresponding o the eight sessions into which the conference was ivided. It is sufficient recommendation to quote rom Sir Geoffrey Taylor's opening remarks that new nd valuable contributions to the scientific study of he processes of particle separation are to be found n all the papers presented to the conference.

## eology in Engineering

y Dr. John R. Schultz and Dr. Arthur B. Cleaves. ith a Chapter on Soil Mechanics by E. J. Yoder. p. ix+592. (New York: John Wiley and Sons, nc.; London: Chapman and Hall, Ltd., 1955.) 0*s*. net.

THIS well-planned and well-written book deals with the application of geology to civil engineer- ng. It is more than a text-book of geology for ngineers, since it discusses geology in such a way that ngineers, on one hand, can appreciate when and to hat extent they may expect the geologist to help hem, and the geologist, on the other, may appreciate he problems with which the engineer has to deal.

The book is concerned with principles rather than ase-histories, because it is the authors' opinion that he engineer will employ the geologist more for the inferences he will make than for his factual knowledge. Attention is directed to the necessity for the geologist to know what the engineer is aiming at in order that he may give the right information in the most useful form, while the engineer, on his part, must be able to appreciate the significance of what the geologist tells him.

The book is divided into twenty-two chapters, of which two-thirds deal with those geological processes and phenomena that have special application in engineering projects and difficulties, and the remainder with specific topics such as dams, reservoirs, roads and tunnels, and with recent developments in the field of soil mechanics and the uses of aerial photography in interpreting soil distribution and recognizing geological structures.

The reproduction of the half-tone illustrations which are distributed through the text leaves much to be desired; but there are many excellent text-figures, a useful bibliography at the end of each chapter, and an adequate index. F. J. North

## The Golden Eagle

King of Birds. By Seton Gordon. Pp. ix+246+16 plates. (London: William Collins, Sons and Co., Ltd., 1955.) 16*s*. net.

MR. SETON GORDON has lived all his life in the Scottish Highlands, has had exceptional opportunities of watching eagles, and has made good use of them. Not only has he kept nests under daily observation from the laying of eggs to first flight of the young, but he has also watched the adults hunting in mid-winter when the hills are covered with snow, and later seen them pair and build the nest. The results of all these observations are presented in a very readable form and include a number of new facts. No attempt is made to estimate the number of breeding pairs of golden eagles; but it may be said that during the past twenty-five years the numbers have been more or less stationary—a decrease in one part of the country and an increase in another. It is interesting to learn that birds have returned to their old haunts in the wilds of Galloway and Carrick and northern Ireland. A chapter is devoted to the use of the eagle in falconry, and we learn that in central Asia birds are used for hunting wolves, foxes and gazelle.

With the advent of sheep farming, and grouse shooting becoming a source of income to Highland lairds, the eagle would have been doomed if it were not for the enlightened policy of some landowners. That the eagle does take lambs at times there is ample evidence, and Mr. Seton Gordon himself has seen one carrying off a lamb. Nevertheless, he considers that "In Scotland the number of lamb-killing eagles is small—less than five percent". He goes on to say that lambs are not a regular prey of eagles in Scotland any more than man is of a tiger. Blue hares and rabbits are the principal food, and one wonders what they will turn to now that the latter have become so scarce.

The eagle's prey is varied and includes various mammals, grouse, geese and other birds. Though a number of grouse are taken, the author does not think they are destroyed in sufficient numbers to affect the stock on a moor; on the other hand, eagles kill grey crows, and it would be interesting to know whether the crow or the eagle has the greatest effect on the grouse population. A number of beautiful photographs adds much to the value of this interesting book. N. Kinnear

# MR. H. N. RIDLEY'S HUNDREDTH BIRTHDAY

By J. W. PURSEGLOVE

Director of the Botanic Gardens, Singapore

DECEMBER 10, 1955, marks the hundredth birthday anniversary of Mr. Henry Nicholas Ridley, C.M.G., F.R.S. He was director of the Singapore Botanic Gardens during 1888–1912, and he will always be remembered in South-East Asia for his vital role in the foundation of the rubber industry and for his gargantuan contribution to our knowledge of the natural history of the area.

While still at school at Haileybury, he decided to devote his life to the study of natural history in the tropics. After graduation at Exeter College, Oxford, he was awarded the Burdett-Coutts Geological Scholarship. In 1880 he was appointed to the staff of the Botany Department of the British Museum in charge of monocotyledons, where he worked until 1887. During this period he became acquainted with many tropical plants and published papers on them. In 1887 he explored the island of Fernando de Noronha, Brazil, and later published accounts of its flora, fauna and geology.

Thus when Ridley arrived in Singapore in November 1888 as the first scientific director of gardens and forests, Straits Settlements, he was well qualified for the tasks which lay ahead. The Singapore Botanic Gardens had been founded on their present site in 1859, although there had been an earlier garden started by Raffles in 1822. Ridley's capability as a research worker and his work on economic crops and tropical botany succeeded in a surprisingly short time in pushing the Singapore Gardens to the fore as a centre of this work.

In the Economic Gardens, now the site of the University of Malaya, he found a plantation of *Hevea* rubber trees, produced from seedlings sent out by Sir Joseph Hooker from Kew in 1877, where they had been grown from seeds collected in Brazil by Mr. H. A. (later Sir Henry) Wickham. The seeds had not been smuggled out of Brazil as is often suggested, but had been obtained by the goodwill and co-operation of the Brazilian Government. Ridley at once began his famous tapping experiments, in which he demonstrated that the trees could be tapped regularly. Recently he told me that when he began he had no idea that rubber would be "a permanently milking tree". This work, together with his experiments on the preparation of rubber and his constant advocacy of it as a plantation crop, often in the face of opposition, led to the foundation of the present industry upon which so large a share of the wealth of Malaya and the eastern tropics has rested. Ridley remained in Malaya long enough to see the fruition of his labour and the great rubber boom of 1910. O. D. Gallagher, in an article in *The Observer* of June 25, 1955, writes: "He is one of the hundred or so men, out of the 2,500 million alive to-day, whose personal efforts have helped decisively to shape our modern life. His rewards have been meagre and mainly abstract. . . . Ridley's name is indelibly rubber-stamped in history."

Ridley's work on economic crops was not confined to rubber; he carried out experiments with most of the actual and potential tropical crops known. He provided not only local planters, but also all other tropical parts of the Empire and elsewhere, wit planting material of rubber and many other crop Visitors from all over the world came to see h experimental and demonstration plots. As early 1889 he reported that cocoa would probably be profi able on the better Malayan soils, while in 1907 h directed attention to the possibility of oil palm as plantation crop. Ridley produced the first writte works of their kind on Malayan timbers, rattans an other forest products, as well as drug plants, fruit and spices. It should be realized that until th formation of the Agricultural Department in Malay in 1904, Ridley and his three assistants at Singapor Malacca and Penang were the only trained men t whom the planting community could apply for tech nical advice and help. Ridley studied in some deta the pests and diseases of the economic crops of th area, and specimens were often submitted to hi by the planters for identification with requests fo advice on their control. In 1891 he founded *th Agricultural Bulletin*, so that he could supply th planting community and others with informatio resulting from his many investigations. He con tinued to edit it until his retirement in 1912, an from 1900 it was published monthly.

"Mr. Ridley's work as a field botanist added mor than that of any other single man to our knowledg of the flora of the Malay Peninsula; his *Flor* (1922–25) is the foundation upon which all futur work must rest." He was an indefatigable collecto and a tireless worker. He made excursions to mos parts of Malaya, often remote, as well as visitin Cocos and Christmas Islands, Borneo, Java an Sumatra. In all, he collected many thousands o specimens, of which a large number were the unknown to science. He named for the first time few thousand plants, and a surprising number o Malayan plants are still only known from his origina gatherings. Nor did he confine himself to plants, o which he collected all groups, but he also collecte many animals as well, mainly vertebrates (excludin fish) and insects. Many plants and animals wer named in his honour, including a New Guinea genu of orchids *Ridleyella* and a moth genus *Ridleyana* It was Ridley who discovered that the ant *Oeco-phylla smarangdina* uses its own larvæ to make silk for the construction and repairing of its nest. Ridley added very considerably to the collection of cultivated plants, both Malayan and exotic, in the Botanic Gardens, Singapore, and brought back living plants from many of his excursions for growing here He sent seeds of the more spectacular plants to Kew, where they were flowered for the first time in Europe. Hand-coloured illustrations and descriptions of some of these were published in *Curtis's Botanical Magazine*, of which Vol. 132 (1906) was dedicated to Mr. Ridley.

His first scientific paper was published while he was still at school, and in all he published more than five hundred papers, articles and books, amounting to some ten thousand printed pages, dealing with tropical agriculture, botany, zoology and geology. A full list of his publications up to 1935 is given in the *Gardens' Bulletin* (9), which was dedicated to him n his eightieth birthday. His encyclopædic volume, The Dispersal of Plants throughout the World", mbodying many original observations, was pub- shed in 1930 when he was seventy-five. Com- ienting on his published work, one critic has said: That there were inaccuracies goes without saying, ut it was just that quality of recklessness in Ridley's rork that enabled him to turn out such vast quan- ities of assimilable knowledge when it was most eeded. A lesser man would have feared for his rofessional reputation, but Ridley was above such etty considerations. The work needed doing, and ith the means at his disposal he did it magni- cently".

Mr. Ridley was secretary of the Royal Asiatic ociety, Straits Branch, during 1889–1911, and editor f its journal, in which he published many original apers. In 1905 he gave the first course of botany ctures to the newly formed King Edward VII ollege of Medicine, now the Medical School at the University of Malaya, and continued these lectures until 1910.

Mr. Ridley was elected a Fellow of the Linnean Society in 1881 and of the Royal Society in 1907. His services were recognized by the honour of a C.M.G. in 1911. His work as a naturalist and in establishing the Para rubber industry has been recognized officially by various scientific and industrial bodies. We are planning appropriate celebrations at the Botanic Gardens, Singapore, on his hundredth birthday, which will include an exhibition of "Ridleyana".

It is my fervent hope that the Singapore Botanic Gardens may long continue as a leading centre of research in tropical botany and a worthy memorial to Mr. Ridley and all that he has done for us during his long and productive life. I am sure that readers of *Nature* will join with me in congratulating Mr. Ridley on the present happy occasion of his centenary and in wishing him "Many Happy Returns".

---

# THE ROYAL SOCIETY

## ANNIVERSARY ADDRESS* BY LORD ADRIAN, O.M., P.R.S.

## AWARD OF MEDALS, 1955

### Copley Medal : Sir Ronald Fisher, F.R.S.

THE rise of quantitative biology, which has been so noteworthy a feature of this century and specially of the past thirty years or so, has been ue above all to the work of R. A. Fisher. The ariability of living things posed problems and raised ifficulties in the interpretation of experimental and bservational data which made necessary something eyond the methods of the physical sciences. They equired in fact a new approach to inductive inference, nd one which would provide means of drawing con- lusions of assessable reliability from variable aterial often available only in small samples. It is o Fisher's combination of mathematical skill and iological insight that we owe the developments, oth theoretical and practical, which have done so uch towards solving this problem and so making iologists of virtually every kind quantitative in heir experiment, their analysis, and, most important f all, their thought.

Faced with the agronomical problems of Rotham- ted, the staff of which he joined in 1919, Fisher egan the remarkable series of statistical investi- ations which gave us the techniques described in 'Statistical Methods", the tabular matter of "Statist- al Tables" (published with F. Yates) for facilitating heir use, and the philosophy of "Design of Experi- nents" by which they may be understood, appreciated nd extended. The outcome has not merely stood he test of time in those branches of biology with rhich Fisher was immediately concerned, but also has ad an ever-widening influence which now extends ven beyond the borders of biology itself. In building he new biometry, Fisher has given especially to the ounger biologists a confidence and quantitative outlook the full effect of which we have still to see.

While Fisher will always be associated chiefly with these developments in statistics and biometry, it should not be forgotten that he has made outstanding contributions in the field of genetics and evolution. He set us on the way towards the modern study of biometrical genetics, and his mathematical treatment of natural selection has provided the basis for much of our present studies of populations. His theory of the evolution of dominance introduced us to the notion of the modification by selection of gene expression, and we owe primarily to him the theory by which we came to understand the working of the *Rhesus* blood groups. He has indeed long been established internationally as well as nationally as one of our leading geneticists, than whom few have done more to further the understanding of evolutionary processes.

### Royal Medal (A) : Sir Alexander Todd, F.R.S.

Over a wide field, Todd has made distinguished original contributions to the chemistry of natural products, more particularly in the field of compounds of physiological importance. His remarkable contributions to knowledge and his brilliance as an investigator have been recognized internationally by both organic chemists and biologists.

Todd joined Sir Robert Robinson in 1931 and played an important part in investigations on the synthesis of anthocyanins. His earlier work included major contributions in the field of vitamin chemistry, for example, in relation to the development of the structure of vitamin $B_1$, and to its synthesis. Independent of Karrer and Fernholz, Todd established the structure of vitamin E and achieved a synthesis. More recently, he has turned his attention to the vitamin $B_{12}$ group, and his degradative and synthetical studies have recently made fundamental contributions to our knowledge of the nature of these substances.

---

* Delivered at the Royal Society on November 30.

Undoubtedly Todd's most outstanding work in organic and biochemistry is in the nucleic acid field. *Inter alia*, he has developed rational methods for the synthesis of natural purine and pyrimidine nucleotides and for their phosphorylation to the nucleosides, including a synthesis of adenosine diphosphate and adenosine triphosphate. These results, among many others, have been achieved by a combination of theoretical knowledge and great experimental skill, aided by modern techniques.

Todd has been a pioneer in the chemistry of cannabinol, a series of complex *bis-iso*quinoline alkaloids, insect pigments (especially the colouring matter of Aphidae), kousso, and natural tropolones of mould origin.

Todd is a most capable investigator ; he has made fundamental contributions to organic and bio-chemistry and is recognized as a leader in these fields.

### Royal Medal (B) : Prof. V. B. Wigglesworth, C.B.E., F.R.S.

Prof. V. B. Wigglesworth has increased our knowledge of almost every branch of insect physiology, and in most cases his work has formed the starting point for other investigators. His contributions to the understanding of those interwoven subjects—growth and cuticle structure—are of paramount importance. It was Wigglesworth who first resolved the epicuticular layer into its four components, showing both the chemical composition and the biological role of these layers, and we owe to him our knowledge of the structure and functioning of the dermal glands. But the formation of the cuticle is inseparable from the study of growth, and following Kopec's first demonstration that hormones were involved in the growth process, the rest of this vast and complex subject belongs to Wigglesworth : the hormonal balance giving rise to nymph or adult, the individual fields of organization in the epidermis, the mechanism of the parallel case of wound healing, and most recently, the way in which various hæmocytes enter into the process.

In the study of respiration, too, Wigglesworth has been a pioneer, and his recent studies on the migration of tracheoles and the effects of low oxygen tensions on tracheal organization have altered our entire concept of this subject.

He has done fundamental work on the digestion of blood meals by parasitic insects, and has demonstrated the formation of a peritrophic membrane in many species by secretion through an annular press. The detailed picture of the histological and chemical cycle of excretion through Malpighian tubules, and the secretory balance of salts and water in mosquitoes are also noteworthy.

From the width of the field covered by his numerous researches, it can be said that Wigglesworth is the 'father' of insect physiology. He has realized the potentiality of the insect as a medium for physiological research, and carried that view into practice with a mastery of observational and experimental methods.

### Davy Medal : Prof. H. W. Melville, F.R.S.

Prof. H. W. Melville occupies a prominent position among those who have developed the extremely important field of the chemistry of macro-molecular substances. He has made many valuable contributions to the study of the mechanisms of the reaction in which such substances are formed, and has devise new experimental methods for the purpose. His earl work on the examination of the various explosio limits in mixtures of phosphorus vapour and oxyge confirmed and extended important results bearing o the early development of the theory of chain reactions especially the role of diffusing atoms and radicals With the discovery of deuterium he examined number of reactions in which the replacement o hydrogen by deuterium contributed to the elucidatio of the mechanism. His work on photochemica reactions sensitized with mercury vapour greatl advanced and clarified this problem.

With this background Melville took up the study o the more complex processes of polymerization and t this field he has made important and lasting contributions. He devised new techniques for the study of th elementary processes which make up the overall chai reaction, and he applied the device of the rotatin sector to the determination of the life-time of transien entities. This work has formed the basis of th quantitative study of free-radical reactivity both fo polymerization and oxidation systems and in man other reactions. Melville and his collaborators hav also made valuable contributions to the methods o synthesis and study of new polymeric systems including recently the interesting group of 'blac polymers'.

Melville's achievements have contributed much t our knowledge of the intricacies of chemical change and his development of new methods and technique for research have had an influence far beyond th confines of his own laboratory.

### Sylvester Medal : Prof. E. C. Titchmarsh, F.R.S.

E. C. Titchmarsh's early work was in the theory o Fourier series and integrals. From this he passed o to a profound study of the special properties of th Riemann zeta-function, a subject which he made ver much his own over a period of many years. His systematic use of Fourier integrals, and in particular o Parseval's formula, led to formulæ that would no have been suggested naturally by other methods, an these formulæ proved to be remarkably fruitful fo the development of new properties of the function.

Some of his work on the order of magnitude of th zeta-function was based on developments of method of estimating trigonometrical sums, due originally t Weyl and van der Corput. He applied these ideas t other problems also, and in particular he effecte significant improvements in the estimation of th error terms in lattice point problems by extending va der Corput's method to double trigonometrical sums

His more recent work has been in the field of eigenfunction expansions associated with second-orde differential equations.

Prof. Titchmarsh has also written a number o important treatises on the various fields within whic he has worked.

### Hughes Medal : Prof. H. S. W. Massey, F.R.S.

Prof. H. S. W. Massey has added greatly to ou knowledge of collision processes between electrons neutral particles and ions. His early work was concerned with elastic and inelastic collisions betwee electrons and atoms. With Bullard he was responsib for some of the early experiments demonstratin iffraction effects. He carried out and directed a rge number of detailed calculations, and, in parti- ular, he exploited the variational method with great horoughness, and did much to give a pattern to the xperimental results by emphasizing the significance f the near-adiabatic conditions.

He was the first to apply the theories of attachment nd recombination to problems of the ionosphere, nd he led the way in reviewing the results of the adio experimenters and in trying to explain them. The difficulties in the way of explanation led him to nvestigate and discuss a wide range of atomic and molecular processes possible in the upper atmosphere. His work, and that of his pupils, is far in advance of any other in this field and has revolutionized our deas about atomic processes in the ionosphere.

Prof. Massey is also the joint author of two important books on the subject of "Atomic Collisions" and of "Electronic Impact Phenomena".

---

## FUNCTIONS OF THE ROYAL SOCIETY

A Royal Medal was awarded ten years ago to Sir Edward Salisbury for his contributions to botanical science. To-day if there were an appropriate medal we ought to give it to him for his contributions in a wider field, as Biological Secretary of the Royal Society. His term of ten years ends at this meeting. We shall all miss the wise counsel he has given the Society, and I count myself extremely fortunate to have held office with a colleague who has endeared himself to Officers and Fellows alike by his kindly understanding of our needs.

We rely on our Secretaries for much more than the supervision of meetings and publications, for they are constantly surveying our activities and must see to it that they are adapted to changing needs. Sir Edward's initiative has widened the scope of our meetings, he has maintained and extended our role in relation to the Commonwealth, and in the field of publications his care in the administration of the Parliamentary Grant-in-Aid has been largely responsible for the improved position enjoyed not only by urselves but also by many other societies as well.

On behalf of the Society, therefore, I thank Sir lward Salisbury for the valuable service he has dered to science during his tenure of office as logical Secretary.

he past year has seen a development in scientific ity which may have great consequences for all and I shall deal with it now because we are ate in having evidence of it at this meeting. I the striking change which has come about in d of international scientific effort. We have d at Geneva a conference on the use of energy at which the experts from every could exchange information in the atmo- nuine scientific co-operation. The geo- onomers, meteorologists and geo- nation have already taken the mbined operations for the ear, and our own Lieutenant-Com- its way to the scene of so much remote parts of the now exchanging eedom, and we our- by the visit of the President of the U.S.S.R. Academy of Sciences and his colleagues during the past fortnight and by their presence at our Anniversary Meeting to-day.

We ought to think of our future rather than our past, but this is an occasion when we cannot be blamed for recalling our long history. When Peter the Great was in London at the end of the seventeenth century, he may well have attended some of the Society's meetings, but unfortunately the names of our visitors then were not recorded. In 1714, however, his fellow-countryman, Prince Alexander de Menzikoff, was admitted a Fellow of the Society, and the notice of his election was signed by our president, Sir Isaac Newton.

When we turn to the record of scientific achievements in the past year it is more difficult to select those which would really justify the use of that overworked epithet 'outstanding'. The passenger who is driven in a modern car along an open road will expect the milestones to recur every minute and will feel that something has gone wrong if they do not. In the past year nothing has gone wrong with the progress of scientific research, in fact the pace is faster than ever; but we are already so used to it that we have come to think more of the danger signals than of the milestones. It is, of course, unfortunate that knowledge can be dangerous, and it would certainly be a disaster if this became an excuse for preferring ignorance; but the danger signals have already attracted world-wide notice and the Society will not need to be reminded of them.

The milestones may have attracted less notice than they deserve: each of us can think of important advances in the field he knows best; but there are two which deserve mention now because our own Fellows have made them and because they are signs of what is likely to be a new phase in our understanding of Nature. I refer to the recent elucidation of the structure of two highly complex molecules, those of insulin and of vitamin $B_{12}$. Both these substances are formed in living cells and play an important part in the vertebrate economy, insulin in sugar metabolism and $B_{12}$ in the formation of the blood cells. Their existence has been known for many years, the use of the naturally occurring products has already saved a great many lives, and there is no immediate prospect of replacing the natural product with one made synthetically. But both are composed of very large molecules with a structure which has presented formidable problems to the chemist, and the solution of these problems cannot fail to enlarge our understanding of biochemical events.

The insulin molecule has a weight of more than 5,000, with two polypeptide chains of unequal length linked by sulphur groups: it has taken Dr. F. Sanger and his collaborators more than ten years to map the entire structure. The molecule of $B_{12}$ has one atom of cobalt and sixty-three of carbon. Dr. Dorothy Hodgkin's X-ray analysis of the crystals has been a remarkable demonstration of the value of this method for mapping such complex molecules: another example of the same thing has been the research on hæmoglobin which Dr. M. Perutz has carried out at the Cavendish Laboratory under the inspiration of Sir Lawrence Bragg, and on the other hand, we have Sir Alexander Todd's studies of the $B_{12}$ group and of the nucleo-proteins, as well as Sanger's of insulin, to show that the organic chemist has not yet lost the power to work out his own salvation by classical methods.

The structural formulæ of these molecules seem terribly elaborate to those of us who are not within the pale. We can applaud such triumphs of chemistry; but they force us to realize how much the living cell must depend on the interplay of very large molecules in which the detailed arrangement of the atoms is of truly vital importance. We may wonder how many such elaborate structures will have to be mapped before we can see the way to general principles; though we are glad to have passed the stage when all that was known of the biochemistry of protoplasm was contained in the two words 'anabolism' and 'catabolism'.

At all events, since the difficulties now are largely technical, it is a comfort to know that the attack on one technically arduous problem has always made it far easier to deal with others of the same order. The successful mapping of large molecules has needed courage and persistence as well as imagination; but the way to further maps will be made plainer. It is a comfort, too, to know that we can confidently expect the unexpected, the advance which may give these problems a new turn. Yet in spite of that, the biologist has little hope of escaping the immense variety of his material. Even when the molecular structures are mapped there will be the organisms to deal with, the vast range of plant and animal form and in the end the differences between one man and another.

Biology, however, is not the only field where there are large territories to be explored in detail before we reach the next eminence. In fact the present course of progress in natural science, rapid though it is, does not suggest that scientific research is likely to change its present specialized character. The regions to be covered become greater and greater, and most of them can only be dealt with by the particular group of experts who know their way into the area.

This brings me back again to an appropriate theme for our annual meeting, namely, the part which the Royal Society should play to fulfil its task of improving natural knowledge.

At the end of his term of office, it is to be expected that your President will have ceased to marvel at his presumption in accepting so exalted a position and will have had time to consider its responsibilities. He will not have had much time, for the work of the Society grows apace; but in spite of that the duties of the President are certainly less arduous than most people might suppose. He is supported at every turn by the knowledge of a great Society at his back and by the Council and the whole staff at Burlington House inspired by an Assistant Secretary with a genius for tactful and effective administration. In fact, the President is so well cared for that it is a wise regulation which sets a limit to his reign.

Fellows will not need to be told of the many fields of activity in which the Royal Society is now engaged. It dispenses grants, awards medals, publishes journals and holds its scientific meetings; but I am convinced that the most important thing it does now is to exist and to perpetuate its existence by electing new Fellows.

Our meetings and periodicals are no doubt the best evidence of our existence; but they are scarcely essential to it. Indeed, their scope needs constant adjustment if they are not to be submerged in the present flood of scientific activity. Every subdivision of science has now begun to organize its special conferences and lectures. With so many subdivisions and so much to publish, the customary medium for printed communications is either a journal devoted to one special field or one which will take the shorter pape and publish them with the least delay. I am no suggesting that our own meetings and journals coul be abolished without great loss, but rather that w should continue our policy of arranging some meeting where the specialist is encouraged to state his cas before an audience of fellow scientists who are not a fellow specialists. That is certainly an important task

In electing new Fellows, however, we perform task which becomes more and more important a natural science expands and subdivides. It is essentia to its progress here that there should be a council o scientists of acknowledged reputation able to form a impartial judgment on the claims of every field an on the merits of those who work in them. Scientifi issues are now of great concern to those who fram the laws and policy of the State, and there must b some independent body to advise on them.

Statesmen and lawgivers are not likely to nee advice on the latest developments of scientifi thought; if they were, they might get better advic from the younger generation who have been trained i modern ideas and techniques and are used to th present scale of laboratory work. What is needed however, is not an academy to pronounce on th controversial points of scientific theory but one wit a reasonable knowledge of the direction in whic research is leading.

We as a Society have never aspired to an organize control of scientific research: even in times of grav national emergency, we have preserved our status as a private body willing to co-operate with the Stat but unwilling to forfeit our independence. It is, o course, true that the Fellows of the Society hav always played a large part in directing research int fruitful channels; but they have done so as heads o laboratories, teachers and leaders of research teams. It is true also that we control funds entrusted to u by past benefactors and that many of these fund must be used for the furtherance of particula branches of science. The value of the funds we hold now amounts to more than a million pounds, and w have also to administer yearly government grants more than £50,000 for aiding scientific researc scientific publications and international activiti These sums, however, are small compared with total which must be spent annually by any cou dependent on machinery, and with the poli system of Great Britain it seems far better fo Royal Society to keep itself outside the State o ization. The larger this becomes, the more imp will it be for us to maintain our status as an pendent body of scientists whose chief obliga the advancement of knowledge.

It is neither necessary nor desirable for the to give any official ruling on scientific issues, are settled far more conclusively in the la than in the committee room. This principle recognized by the Royal Society since its f and it is stated specifically in the adver the *Philosophical Transactions* in 175 out "that the certainty of the facts of the reasonings contained in published must still re of their respective a on to say "that it i to which they w their opinion as Nature or Art, th position almost goes on: "A equently proposed from the chair, to be given to e authors of such papers as are read at their accus- med meetings, or to the persons through whose nds they have received them, are to be considered no other light than as a matter of civility, in return r the respect shown to the Society by those ommunications".

This stern insistence on our impartiality has not evented us from issuing reports from time to time hen the occasion seemed to demand them. There e, for example, the reports of the Food Committee ring the First World War. But it has never been ggested that the Society assumed any other sponsibility than that of choosing the committee of perts to draw up the report.

That, however, is the kind of obligation which the oyal Society should be specially fitted to discharge. is right that the State should obtain the best ientific advice on practical issues, and it must know here to turn for the best panel of advisers. There e, of course, numerous societies to deal with parti- ular fields, and some of these would be just as ompetent to nominate experts from their member- ip. But the fragmentation of science has left dis- uted borderlines as well as unclaimed territory, and our Fellows have been properly chosen we should e able to justify the claim to represent all branches science at the highest available level. Although we o not pronounce officially on matters of scientific ontroversy, we can say who are the leaders in any eld and we know what sort of people they are.

If this were our only, or our principal, function it ight seem to reduce our status to that of a scientific nployment agency ; but the applications of science e now of such consequence that the State must be rced to spend more and more of its income on ience and technology. With scientists in short sup- y it must expand research, teaching and develop- ent. It must be careful not to harness too many tive investigators to desks in Whitehall or to the ommittee rooms of universities, yet its administra- on must show an understanding of scientific needs. e cannot blame government departments and inisters for mismanaging scientific affairs if we are nwilling to assume our responsibility for aiding them.

How far then does our constitution and our present actice fit us for such responsibilities? This year arks the death two hundred years ago of a great olitical scientist, the Baron de Montesquieu, a ellow of the Royal Society who was renowned in ery country for his analysis of the principles of overnment. Montesquieu came to us from France d was impressed by the precautions against auto- acy inherent in the British constitution. It is true at his praise of the liberal form of government eveloped in Britain was linked with the suggestion at the weather had a great deal to do with it. He ys : "In a nation so distempered by the climate as to ve a disrelish of everything, even of life, it is plain at the government most suitable to the inhabitants that in which they cannot lay their uneasiness to a ngle person's charge". But his analysis of our laws ade him conclude that we were, or at all events had e opportunity to be, the freest country in the world d that it is in our nature to defend our liberties m autocratic control.

do not think our procedure for the election of new ows could be made more representative than it is It may not be strictly democratic, for the elec- must be made by the existing Fellows, but we from every field of natural science and our ages vary within reasonable limits. At present our youngest Fellow is thirty-one, and Council this morning authorized the dispatch of a letter conveying the congratulations of the Society to our colleague, Mr. H. N. Ridley, whose hundredth birthday falls on December 10. We have to be constantly on the watch to avoid neglecting the claims of scientists whose work cuts across the standard classification. But the machinery is elastic : I have seen it at work over a fairly long period and I have always been impressed by the individual capacity for honest judgment which goes to the formation of a collective opinion on scientific merit. It is certainly a responsibility which we do not take lightly, and it is right that it should occupy much of our time in the early months of the year. Whatever else we should be doing, this is time well spent.

But nowadays the Society has many other things to do, and I am not sure that we have evolved the system of self-government which enables us to give adequate consideration to all of them. Election to our Council must be governed by the need to keep a balanced representation of different branches of science. Council would soon become ineffective if its numbers were expanded to keep pace with every new development ; but with a body of only sixteen members, apart from the Officers, to represent our 560 Fellows, it is naturally difficult for more than a small proportion of the Society to gain any insight into the way in which its business is conducted. For those who are chosen to serve on the Council the volume of business to be decided must often seem far too great for meetings which can rarely last much longer than 1¼ hours and occur only twelve times a year. Naturally a great deal of the work falls on the Secretaries, who must be prepared with advice on many of the matters which do not involve major issues ; but even though the Council is willing to accept this advice without lengthy discussion, there are certain important decisions to be made at each meeting, and it is very difficult to find the additional time needed for the discussion of more general problems. With the present growth of scientific effort, problems of general policy are bound to be in our minds, and I know that the President must often have seemed unduly repressive when there is a long agenda and the Council meeting must be ended in time for the Ordinary meeting of the Society.

I have no solution to offer which would not involve more time spent in committee rooms and less in our laboratories. That may be a burden which we must accept. But I would urge the Society that it should act only as an adviser, and should not be willing to accept the kind of detailed administrative work which it is sometimes asked to undertake. Our difficulties arise from the fact that our responsibilities have grown. We must be constantly on guard to see that we have the leisure to survey them.

My successor with his new Officers and Council will have troublesome decisions to face ; but we need not fear that the Society will ever be in danger of becoming less representative of science as a whole or less important in the affairs of the country. Your President becomes increasingly aware of its importance as he learns the duties of his office. Some of them are onerous ; but it would be absurd to suggest that he has a thankless task in representing our great and ancient Society. So in conclusion all that I need add is the earnest hope that my successor will find his position as enjoyable as I have found it during these past five years.

# RESPONSES OF A FERN APEX TO DIRECT CHEMICAL TREATMENTS

By PROF. C. W. WARDLAW
Department of Cryptogamic Botany, University of Manchester

THE organization and morphogenetic activity of a fern apex, that of *Dryopteris austriaca* (*D. aristata*), have been further investigated by observing how it responds to direct applications of solutions of various organic substances. This work was undertaken, partly in an attempt to explore the concept of the apical meristem as a complex reaction system[1], and partly because the technique of organ-culture, though it has been a means of obtaining interesting and important information on growth, has thus far yielded little new information on the primary morphogenetic activity of the apical meristem. Thus, in aseptic culture media of highly diversified composition, the growth of excised fern apices may be increased, decreased or inhibited; but no fundamental change in their primary morphogenetic activity has been reported[2,3].

The present work was also prompted by the view that the important advances now being made in the chemical study of apices[4,5] should be complemented by experiments in which the more important metabolites disclosed by these and other studies should be applied directly to embryonic tissues (including embryos and meristems).

The first stage was evidently to ascertain if the fern apex does, in fact, react in novel ways to direct applications of different physiologically active substances. In the preliminary experiments briefly considered here, large apices of *Dryopteris austriaca* were laid bare, treated for periods up to about twenty days with solutions of substances such as 3-indole acetonitrile, dinitrophenol, maleic hydrazide, yeas extract, glutamine, etc., retained in small pads c absorbent cotton wool, and examined at frequen intervals under a binocular microscope, with sub sequent microscopic study of fixed and sectione materials. Some work along the same general line both on apices and embryos, has already bee reported by other investigators[6–9], and there is als a considerable literature on the morphogenetic effec induced by spraying physiologically active substanc on older regions of the plant. Among the advantag of my procedure are that the very earliest visibl evidence of any unusual morphogenetic developme can readily be observed and that reactions of transitory nature are not overlooked. (The gener term 'apex' here denotes the distal region of th shoot, comprising the conical apical meristem an the wide subapical region. The apical meriste consists of a superficial layer of distinctive embryoni cells occupying most of the terminal conical regio the youngest leaf primordia arising within th meristem.)

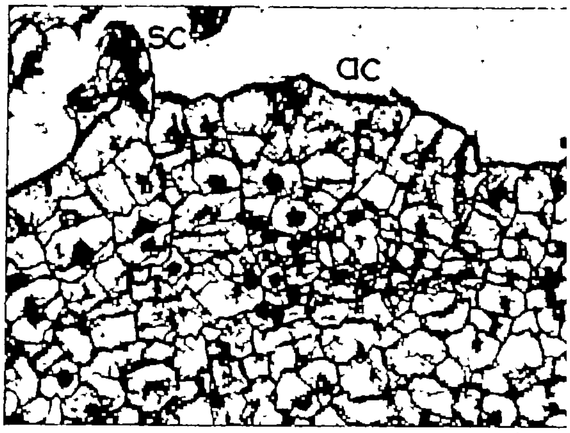

Fig. 2. Longitudinal median section of an apex treated with thiamine hydrochloride, showing the parenchymatization of the apical cell region (*ac*) and the precocious formation of scales (*sc*) over the meristem. (× *c.* 180)

(*Photos in Figs.* 2, 3, 5 *by Ernest Ashby*)

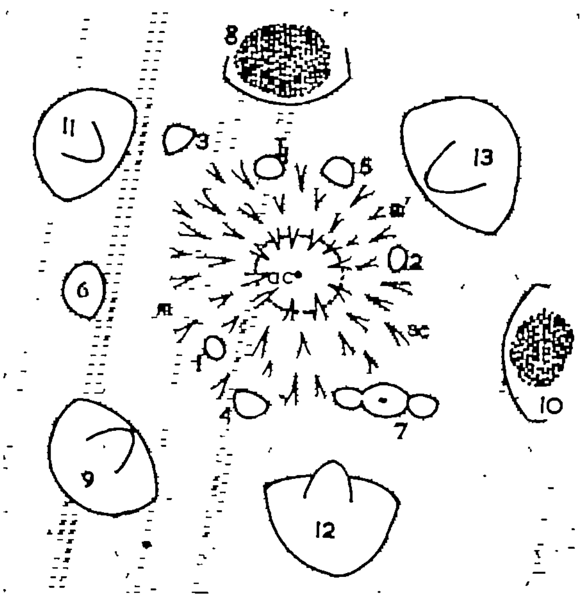

Fig. 1. *Dryopteris austriaca.* Apex as seen from above, after treatment with yeast extract. The original conical apical meristem, indicated approximately by ---$^1$, has become almost completely flat and scaly (*sc*) close to the apical cell (*ac*); primordia $P_1$–$P_7$ and the new primordium at $I_1$ have remained small and have become relatively widely separated; the apex of $P_7$ was slightly injured and two lateral primordia have formed; $P_8$ and $P_{10}$ were damaged at the outset; the broad subapical region is stippled. (× *c.* 17)

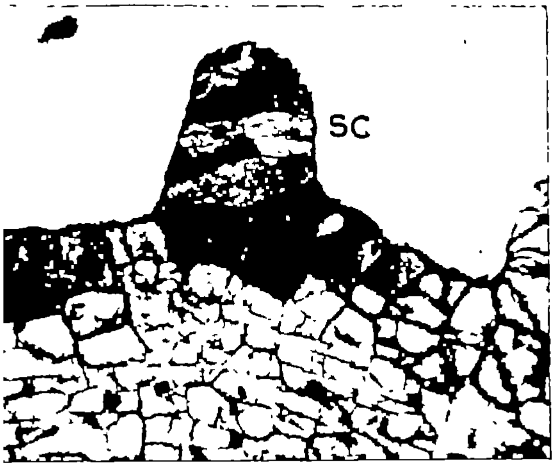
Thus far, it has only been possible to test a limite number of substances; but in most cases some re action was obtained, and already many developmen of morphogenetic interest have been observed. Thes include: an increase in the rate of growth in th subapical region; an arrest or slowing down growth in the apical meristem; the formation flattened and of sunken, cup-shaped apices; t formation of double, treble and quadruple primordia, of two primordia in a single leaf site, of centric (or radial) leaves; the occasional pression of primordia; the reversal of the phyllot spiral; the induction of buds on meristems wit uninjured apical cell; the promotion of root fo tion and growth; the formation of scales o apices of young leaf primordia and leaf sites, ar precocious formation of scales (which are not p



ʼig. 3. Longitudinal median section of an apex treated with ʼeast extract. The region of the apical cell has lost its distinctive ʼharacter: it is becoming parenchymatous and has given rise to a large spine-like scale (sc). (× c. 180)

ı the normal apical meristem but only on the ılarging subapical region) over the whole of the ›ical meristem, including the apical cell; and the ʼecocious parenchymatization of the meristem, ʼcluding the apical cell.

Although some treatments have resulted in extenʼve morphological changes, nevertheless it has ›come evident that certain aspects of apical organʼation and activity are not readily modified. Thus, hen apices were treated with yeast extract, or with ıiamine hydrochloride, the meristem became scaly l over and parenchymatous (Fig. 1), the apical cell so became much divided (Fig. 2) and sometimes ıve rise to a spine-like scale (Fig. 3). Buds, which ›ver occur on the normal intact apical meristem, ere sometimes formed on these apices. Neverthess, these and other apices, in which extensive .odifications were being induced, continued to give se to leaf primordia in normal positions for some me. In some, usually vigorously growing, apices, ıere was sometimes a return to the normal organoʼnic activity when the treatment had been dis›ntinued for some time.

The evidence thus far obtained indicates that the ʼocedure adopted may well yield information on the ʼganization and reactivity of the apical region that ıay not be forthcoming from organ- and tissueılture investigations. An example may be cited. ʼhen autoclaved yeast extract was an ingredient of ›lid culture media in which excised (or explant) fern pices were being grown, the overall growth of the ʼplant was greatly increased; but its morphological evelopment was quite normal[9]. But when the same oncentration of yeast extract (unautoclaved), or a ›lution of thiamine hydrochloride, was applied ʼirectly to the apex, the somewhat novel results ıdicated above were obtained (Figs. 1–3). It need ›arcely be said that much further work is necessary › explore adequately this interesting aspect.

In earlier work, it was shown that certain characʼristic morphological and histological developments ın be induced at will by appropriate surgical treatıents[10]. Comparable developments have now been ›btained by the direct chemical treatment of the ›ex. If, for example, the shoot apical cell is puncʼred, or if it remains intact and active but is isolated ʼm a young leaf primordium ($P_1$) or from a primordium site ($I_1$) by a deep and wide tangential incision, buds are usually induced in these and other positions[11]. In different chemical treatments (yeast extract, dinitrophenol, maleic hydrazide), in which the normal activity of the apical cell group was arrested or radically modified, buds were formed in $P_1$, $I_1$ and other positions (Fig. 4). On the evidence of the surgical experiments, the inhibition of buds in or near the apical meristem in the normal *Dryopteris* apex was attributed to the organization and growth of the apex as a whole and not to a *direct* inhibiting effect of an auxin, proceeding from the apical cell group, on a young primordium or primordium site[12]. The present experiments support this view: buds were not only formed around an isolated, intact apical meristem during continuous application of a range of physiological concentrations of 3-indoleacetonitrile and 3-indoleacetic acid, but also they grew vigorously and had a strong vascular development. Where the apex had been damaged, the vascular systems of these buds spread across the medulla of the parent shoot, Fig. 5.

In the normal development of *Dryopteris*, a steady relationship is maintained between the apical meristem and the subapical region, the embryonic cells near the base of the conical meristem being successively differentiated into the tissues of the subapical and maturing regions. Indeed, except for a gradual ontogenetic increase in size, the apex remains relatively unchanged in configuration and morphogenetic activity over many years. This steady relationship of the apical meristem and the subapical region, and the perennially embryonic condition of the former, have been more or less considerably modified by some of the direct chemical treatments given in these experiments. The effects observed can be referred, directly or indirectly: (1) to an increase in the relative rate of growth in the subapical region; (2) to an arrest of growth, or a greater relative

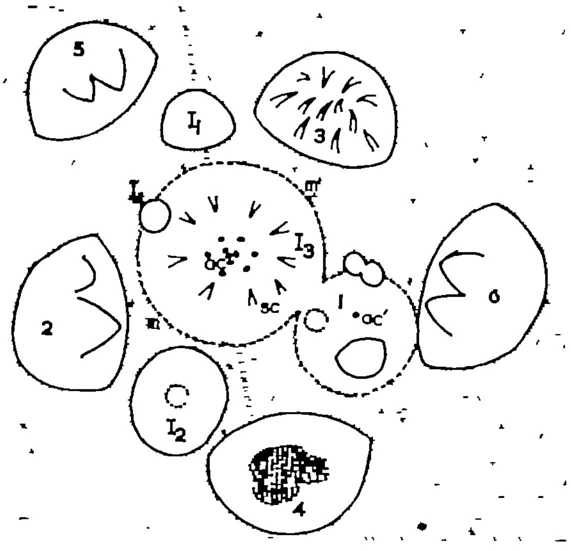


Fig. 4. Apex as seen from above, after treatment with dinitrophenol. Several of the primordia present at the beginning of the experiment have become double; the apex of primordium 3 ($P_3$) has become scaly; $P_1$ has become a bud, with three leaf primordia, the second of which is double; $P_4$ was damaged at the outset; the second new primordium ($I_2$) is centric and no primordium has been formed in the normal $I_1$ position; the apical meristem is becoming scaly (sc) and small scales can now be seen close to the apical cell (ac); the circular broken line ($mm^1$) indicates approximately the base of the apical cone; the broad subapical region is stippled. (× c. 7·5)

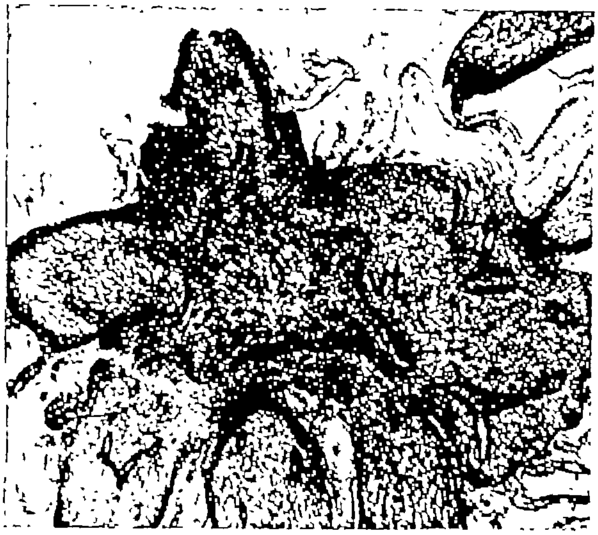

Fig. 5. Transverse section of a shoot in which the distal region of the apical meristem became damaged during treatment with 3-indoleacetic acid in lanoline. The several large buds which were formed close to the injured region have given rise to a large, stellate mass of vascular tissue (*vt*) in the medulla of the parent shoot. (× 12)

decrease in the rate of growth, in the apical meristem; (3) to a precocious parenchymatization of the meristem. In some instances processes (1) and (2) may both be involved. Where a rapid relative growth of the subapical region has been stimulated, as in treatments with indoleacetic acid and indoleacetonitrile, a depressed or cup-shaped distal region results, this being the normal conformation of the apex in some other large fern species. In (1) and (2) above, the young leaf primordia, which occupy positions in the transition zone between the slow-growing apical meristem and the more rapidly growing subapical region, may, in different instances, either participate in the enhanced development or be subjected to a tangential tensile stress. In both circumstances some abnormal tangential development of primordia is to be expected, and, in fact, tangentially extended primordia, double, treble and quadruple primordia, and two contiguous primordia occupying a single leaf site, have been observe These observations support my view on the causatic of the shape, symmetry and orientation of le primordia, based on direct observation and surgic experiments. According to this view, the characte istic phenomena of leaf formation and developme are referable : (*a*) to the inception of growth centr near the base of the conical apical meristem, ar (*b*) to the distribution of growth in that region, bot of these being functions of the organization of th apex as a whole.

In these experiments some of the substances ma have entered the superficial cells of the apical mer stem directly, they may have entered by way of th subjacent parenchymatous cells, or they may hav gained access by way of wounds. This aspect of th work, which carries its own interest, needs muc fuller investigation. Some preliminary investigatio have, in fact, been carried out. For the present, may be noted that many different substances ca enter the tissues of the apical meristem or the sul jacent region and induce changes in its norm functioning. Accordingly, an intensification an diversification of work along the lines adopted in th preliminary exploration may well yield substanti information on the reactivity of cells in differe regions of the apex and on the processes involved i the differentiation of embryonic cells. Contemporar investigations support the view that this is the kin of information that is now most needed if we ar to make progress in elucidating the problems morphogenesis.

A fuller account of these observations will be give elsewhere.

# NEWS and VIEWS

## Royal Society: Officers and Members of Council

At the anniversary meeting of the Royal Society on November 30, the following officers and members of Council were elected: *President:* Sir Cyril Hinshelwood, Dr. Lee's professor of chemistry in the University of Oxford; *Biological Secretary:* Prof. G. L. Brown, Jodrell professor of physiology at University College in the University of London; *Physical Secretary:* Sir David Brunt; *Foreign Secretary:* Dr. H. G. Thornton, head of the Department of Soil Microbiology at Rothamsted Experimental Station; *Treasurer:* Sir Thomas Merton. *Other Members of Council:* Prof. T. A. Bennet-Clark, professor of botany in the University of London, King's College; Dr. B. Bleaney, demonstrator and lecturer in physics, University of Oxford; Prof. F. W. R. Brambell, Lloyd Roberts professor of zoology in the University of Wales at the Universit College of North Wales; Dr. Mary L. Cartwrigh mistress of Girton College and University lecturer i mathematics in the University of Cambridge; S Alan Drury, member of staff of the Agricultur Research Council; Prof. J. H. Gaddum, professor pharmacology in the University of Edinburgh Sir Claude Gibb, chairman and managing director C. A. Parsons and Co., Ltd.; Prof. L. Howarth, profe sor of applied mathematics in the University Bristol; Prof. W. B. R. King, formerly Woodwardi professor of geology in the University of Cambrid Prof. K. Mather, professor of genetics in the Univ sity of Birmingham; Prof. J. S. Mitchell, profe of radiotherapeutics, University of Cambridge, director of the Radiotherapeutic Centre, Add brooke's Hospital, Cambridge; Prof. N. F. M Cavendish professor of experimental physics in

University of Cambridge; Sir Rudolph Peters, professor emeritus of biochemistry in the University f Oxford; Prof. J. M. Robertson, Gardiner professor f chemistry in the University of Glasgow; Dr. B. F. J. Schonland, deputy director, Atomic Energy Research Establishment; Prof. M. Stacey, professor f chemistry, in charge of organic and biological hemistry, in the University of Birmingham.

## ir Cyril Hinshelwood, F.R.S., President of the Royal Society

This election of Sir Cyril Hinshelwood as president f the Royal Society will be acclaimed not only by his scientific colleagues, but also by the host of his past students, now dispersed in the chemical industry and elsewhere. As a fellow and tutor of Trinity College, and afterwards Dr. Lee's professor of chemistry at Oxford, his influence and inspiration have been profound. The dominant theme of his esearch has been the elucidation of chemical processes by kinetic methods, and much of it is characterized by a design which enabled him to obtain answers to questions of great complexity using elatively simple experimental technique. He first clarified the processes of molecular activation in homogeneous gas reactions, and made vital contributions to our understanding of thermal chain reactions. Similar considerations were then applied to eactions in the liquid phase. More recently, he has used the same systematic analytical approach in exploring the problems of bacterial growth, a method at first received with some scepticism by more professional biologists, but which has now led to results of fundamental value in connexion with processes of bacterial adaptation. His several authoritative books on these subjects are recognized by their eloquent clarity, and reveal his vividly philosophical approach towards the underlying unity and pattern of natural phenomena.

Sir Cyril's previous distinctions include the Davy and Royal Medals of the Royal Society, of which he has been foreign secretary for five years past, and others of the Chemical Society, of which he is a former president, as well as many other honours bestowed by foreign scientific academies. He has served on many government advisory bodies, was recently chairman of the Fuel Research Board, and s a member of the Advisory Council on Scientific Policy. To all these scientific qualities, Sir Cyril also adds a remarkable command of foreign languages, much achievement as a connoisseur of art and as a painter in oils, and a conversance with classical and modern literature in many tongues. Through his pursuit of natural knowledge and through his distinctive qualities, Sir Cyril is eminently fitted to uphold the high traditions of his new office.

## Genetics at Glasgow: Prof. G. Pontecorvo, F.R.S.

The establishment of a chair and the appointment of Dr. G. Pontecorvo as its first occupant complete the administrative arrangements for genetics at the University of Glasgow. A lectureship established in 1945, to which Dr. Pontecorvo was appointed, developed into a Department of readership status with increasing teaching commitments and with an active research school supported by the three Research Councils, the Nuffield and the Rockefeller Foundations and industry. The readership is now raised to the status of chair.

After graduating at Pisa—his birthplace—in 1928, Dr. Pontecorvo was engaged for about nine years in Florence in research on the applications of genetics to animal breeding. In 1938 he had to leave Italy as a consequence of political conditions, and found hospitality at the Institute of Animal Genetics, University of Edinburgh, then directed by Prof. F. A. E. Crew. There the opportunity of working on the genetic effects of radiations under the inspired leadership of Dr. H. J. Muller shifted his interests from applied to fundamental genetics. Since then Dr. Pontecorvo has held successive research and staff positions in Glasgow, Edinburgh, and finally in Glasgow again. His contributions to genetics are in several directions. He was one of the early investigators of the lethal effects of radiations in the first generation of irradiated individuals. With Muller he designed an ingenious method to investigate genetic differences between species the hybrids between which are sterile. With Prof. E. Hindle, he investigated the cytology of the human louse and the genetic mechanisms underlying its sex-ratios. In 1943 the demand for penicillin led him to work on the genetics of *Penicillium*. This marked the beginning of his interest in the genetics of fungi, both *per se* and as a powerful tool in investigating the ultra-microscopic organization of the gene. These two lines of interest have been pursued side by side for the past ten years by the research team led by Dr. Pontecorvo and including, among others, Dr. J. A. Roper. The work on the genetics of fungi has led to the discovery of alternatives to sexual reproduction in fungi in which this does not occur. The work on the gene has led to the view that it is a compound structure with many sites of mutation which crossing-over can distinguish from one another.

## Colonial Section of the Road Research Laboratory: Dr. R. S. Millard

Dr. R. S. Millard has been appointed head of the newly formed Colonial Section of the Road Research Laboratory with the rank of deputy chief scientific officer. Dr. Millard was educated at Queen Elizabeth Grammar School, Ashbourne, and at University College, London, where he obtained first-class honours in civil engineering in 1941. After experience with a civil engineering contractor, he joined the Bituminous Materials Section of the Road Research Laboratory, Harmondsworth, in 1944. In 1949 he was appointed officer-in-charge of the newly formed Scottish Branch of the Laboratory. In March 1951 he returned to Harmondsworth as head of the Bituminous Materials Section, and he has served in this capacity up to the present time. The tasks of the Colonial Section will be to apply the basic knowledge already available at the Road Research Laboratory to problems of road design and construction in the Colonies, and to extend this knowledge by research. The Section is being established at the Road Research Laboratory, Harmondsworth, where most of the laboratory work will be done. Field-work and full-scale road experiments in collaboration with the Colonies themselves will form an important part of the work of the Section.

## Textile Institute: Supplemental Royal Charter

The authority of H.M. the Queen has been given for the granting to the Textile Institute of a supplemental royal charter, extending the powers granted to it by the original charter of 1925. The supplemental charter authorizes fellows and associates of the Institute to practise and describe themselves as chartered textile technologists, and new by-laws provide that the Institute may elect 'companions', an honour conferred on members who, while not being chartered textile technologists, have yet advanced the general interests of the textile industry. The Institute is also now authorized to grant the status of licentiate to members who have attained the age of twenty-three and have obtained such certificate or diploma as the Institute may consider to provide sufficient evidence of education in textile subjects.

## Commonwealth Fund Grants for Medical Education in the United States

The Commonwealth Fund, New York, has given 7,150,000 dollars to ten university medical schools in the United States, to be used as the recipients deem wise, for strengthening their medical education programmes during the next few years. These special grants, which have been drawn from capital, are in addition to the Fund's annual contributions from its income, totalling 2 million dollars during the past ten years, to specific medical education projects, community health services and other traditional interests normally supported from current income. The medical schools receiving the new grants are: Chicago, 500,000 dollars; Columbia (Physicians and Surgeons), 750,000 dollars; Cornell, 750,000 dollars; Emory, 600,000 dollars; Harvard, 1,000,000 dollars; New York University, 750,000 dollars; Southern California, 300,000 dollars; Tulane, 750,000 dollars; Western Reserve, 1,000,000 dollars; and Yale, 750,000 dollars. The Commonwealth Fund was established in 1918 by Mrs. Stephen V. Harkness with the motto, "To do something for the welfare of mankind". During recent years its primary interests have been in the field of health, particularly in medical education, medical research and community health.

## Vannevar Bush Fellowships in Earth Sciences

The Department of Geology and Geophysics of the Massachusetts Institute of Technology and the Geophysical Laboratory of the Carnegie Institution of Washington are co-operating in the award of pre-doctoral fellowships in theoretical and experimental geology. The award will be known as the Vannevar Bush Fellowships in Earth Sciences, in honour of Dr. Vannevar Bush, who has given long service as professor and, later, dean and vice-president of the Massachusetts Institute of Technology and more recently as president of the Carnegie Institution of Washington. In general, recipients will spend at least three or four terms in the Carnegie Institution doing laboratory work and one or two terms in the Massachusetts Institute analysing and writing up their results. Throughout their work they will be registered full-time candidates for a Ph.D. of the Massachusetts Institute and will be under the supervision of a senior member of the Department of Geology and Geophysics there. The value of the fellowships will be 200–225 dollars a month. Further information can be obtained from the Chairman, Department of Geology and Geophysics, 24–302 M.I.T., Cambridge 39, Mass.

## Instrumentation and Accessories for Radioactive Isotopes

The Scientific Instrument Manufacturers Association, in collaboration with the United Kingdom Atomic Energy Authority, has published a most useful brochure, "Radio Isotope Instrumentation and Accessories" (pp. 124; from the Association, London; 1955), which will be of great assistance to the potenti user of radioactive isotopes in selecting electroni equipment to suit his special needs. Compiled b Dr. D. Taylor and Mr. A. G. Peacock, the brochur contains an introductory section in which fundamental data with regard to radioactive measurement and instrumentation are discussed and show graphically or in tabular form, followed by a serie of manufacturers' illustrated announcements an specifications of nucleonic and electronic equipment Details are given of the various detector element and associated apparatus used for radioactive assa and radiation monitoring, and of the availability o special equipment for research in nuclear physics an radiochemistry. Inquiries regarding the equipmen described should be addressed directly to the manufacturers concerned; but special inquiries may b sent in the first place to the Head of the Electronic Division, Atomic Energy Research Establishment Harwell. Information and advice concerning th availability and uses of the isotopes themselves ar not given in the brochure, but can be obtained from the Isotope Information Office at Harwell.

## Scottish Field Studies Association

The Scottish Field Studies Association has now been in existence for six years, and during that time and in face of great difficulties, has done much t extend interest in natural history in Scotland Perhaps less well known than the field centres i England and Wales, the Scottish Centre at Garth ha continued to develop in spite of the fact that us has to be made of a working youth hostel for accommodation and that a warden could only be appointe on a part-time and often voluntary basis. Beside five open courses, seven schools or colleges made us of the centre, giving a total of 1,450 student-day spent at Garth in 1954, an increase of 150 over 1953 The Association now feels that the arrangement a Garth is unsuitable, and one of its most activ members, C. I. C. Murdoch, makes a powerful cas for the setting up of a permanent centre in uppe Speyside between the three great hill masses of th Monadhliaths, the Grampians and the Cairngorms other members of the Association are keen o developing a centre in North Argyll. All who ar interested in the setting up of a permanent fiel centre in Scotland or wish to develop field studie are invited to get in touch with the secretary of th Association, B. W. Gibbons, Department of Botany The University, Glasgow, W.2.

## Schools Service of the National Museum of Wale

The Schools Service of the National Museum o Wales covers the whole of Wales and Monmouthshir and is thus national in scope. It began in 1949, an it is appropriate that an attractive illustrated brochur about it should now be published under the title o "The First Five Years" (pp. 12; from the Museum Cardiff; 1955; 6*d*.). The position to-day is tha there are five officers, and every term more than tw thousand exhibits are distributed between th secondary schools of the area served. The number o eligible schools is 365, of which more than half tak part in the Service. The personnel and administration have been added to the already crowded Departments of the Museum, though during the period unde review it has been found possible to construct special room for the craftsmen and also provide new garage for the two vans. Recently some basement accommodation was adapted to form a stor with its own entrance and assembly point. The service is intra-mural as well as extra-mural, and large numbers of school classes are received in the Schools Service Reception Room. Naturally, this part of the Service is of greatest use to the Cardiff schools. The aim of the Service is "to teach, to interest, and to inspire through objects". It is pleasing to note that this aim has been faithfully followed throughout the five years, for it is the fundamental aim of all museum work. Although the Service was designed to help the schools, it is also interesting to recall that it has been of reciprocal service to the Museum, and many objects of value have been offered by discerning children.

## Self-Inhibition in Germinating Rust Uredospores

It has been observed that germinating uredospores of rust fungi produce a volatile substance which, under certain conditions, inhibits the elongation of the germ tube. This phenomenon has now been investigated in greater detail by F. R. Forsyth (*Canadian J. Bot.*, 33, 5, 363; 1955). He reports that the self-inhibition of germination of uredospores of *Puccinia graminis* Pers. var. *tritici* Erikss. and Henn. has been consistently demonstrated in Warburg flasks. Four ways of overcoming the effect of the inhibitory substance have been discovered: the use of a sufficiently large volume of water in relation to weight of spores; the placing of a silver nitrate solution in the centre well; and the introduction of acetone or ammonia vapour into the flask atmosphere. The vapour of trimethylethylene inhibits germination of the uredospores in the same way that the natural inhibitor does, and the same means can be used for counteracting its effects. The similarity of the absorption spectra of the inhibitor and of trimethylethylene in acetone solutions indicates that trimethylethylene is the natural inhibitor. Cyclohexene has formative and inhibitory effects on the germ tubes, and these effects can be overcome by vapour of acetone.

## Physiological Genetics of the Garden Pea

In grafting experiments using early and late varieties of *Pisum*, D. M. Paton and H. N. Barber (*Austral. J. Biol. Sci.*, 8, 2, 231; 1955) have found that when genetically early scions of *P. sativum* var. Massey are grafted on to genetically late stocks of var. Telephone, flowering on a higher node results. In reciprocal grafts, the scions of the late variety flower at an earlier (lower) node. Control grafting, that is, scions to stocks of the same variety, has no effect on Massey scions but leads to flowering at a lower node in the Telephone scions. Removal of cotyledons as soon as possible after germination (3–7 days) has no effect on Massey but leads to earlier flowering in Telephone. The authors consider that these results are best explained on the assumption that the genetically later variety produces a flower inhibitor (or delaying) substance which can pass a graft union and alter the flowering behaviour of genetically early scions.

## Meteorological Observations of Solar Radiation during an Eclipse

A paper by R. Dogniaux on "Observations of the Solar Radiation during the Eclipse of the Sun on June 30, 1954" (Pub. No. 13, Sér. *B*, Institut Royal Météorologique de Belgique, Bruxelles) describes the results of determining the radiations of the sun during the greatest phase (0·774), at Uccle, of the eclipse of June 30, 1954. Six figures show the results under various conditions, and from them the reductions in brightness during the course of the eclipse were calculated. The direct solar radiation was reduced to 14 per cent at the instant of greatest phase, diffused radiation to 35 per cent, and the total brightness to 25 per cent. With the aid of photoelectric cells, similar observations of the radiations to which the human eye is sensible were made, and it was found that these were reduced to 20, 28 and 12 per cent for the total, diffused and direct radiation on a horizontal surface, respectively. One of the figures shows the temperature reductions during the eclipse under a ventilated shelter on a platform, at a distance of 1 cm. under bare ground and also at a distance of 1 cm. under grass. Although it is certain that the effect of the eclipse is shown in the changes of temperature, and in particular under the bare earth, as revealed by the first graph of this figure, it is impossible to decide what percentage of this was actually due to the eclipse. The variation of cloudiness was such that its effect was very pronounced; nevertheless, the results show that the propagation of the heat differed for air, bare soil, and soil protected by grass.

## Thirtieth International Congress of Americanists: Proceedings

The thirtieth International Congress of Americanists met at Cambridge in August 1952, under the presidency of Mr. J. Eric S. Thompson, the distinguished Maya epigraphist, and the proceedings have now been published (pp. 250. London: Royal Anthropological Institute). Americanist Congresses, which in the words of their statutes have for their object "the historic and scientific study of the two Americas and their inhabitants", normally take place every two years and alternate between the Old and the New World. The thirtieth Congress was the first to meet in England since 1912, when the eighteenth Congress met in London. The terms of reference of these Congresses admit a wide range of subjects, and only a few of the thirty-seven published papers can be mentioned here. By far the most interesting communication is an account of the recent explorations at the great Maya site of Palenque by Señor Alberto Ruz, in which he describes the discovery of an important burial chamber beneath the Temple of the Inscriptions, an outstanding instance of the rare practice of burying notable people beneath an American temple-pyramid. There are several other papers in the Maya field, including one on the Maya character by Mr. Thompson. Other interesting archæological papers are on the excavation of a shell mound, or sambaquí, in Brazil, by Prof. L. de Castro Faría, and on transport in Peru, by Dr. Paul Kosok. In linguistics there are two papers on Alaskan languages by Prof. L. L. Hammerich; in ethnology a study of the peyote cult by Dr. Ruth Underhill; and on the historical side a note by Dr. M. Ballesteros-Gaibrois on a manuscript of Fray Martín de Murúa, "Historia General del Perú", in the possession of the Duke of Wellington. Mr. Thor Heyerdahl has three papers relating to his theories of the population of Polynesia by voyagers from South America, which aroused some popular interest at the time of the Congress, although he had as 'rough' a time in the discussions as ever he had on the Kon Tiki raft. A feature of the Congress was a notable loan exhibition of nearly all the ancient Mexican manuscripts in Great Britain, to which was added a series of fine unpublished drawings from the North American and Brazilian expeditions of Maximilian, Prince of Wied. The papers include a comment on these by Dr. J. Röder and a biographical note on his ancestor by Karl Victor, Prince of Wied. The publication of these proceedings was considerably delayed, and the thirty-first Congress was held at São Paulo before they appeared. The thirty-second Congress, to be held in Copenhagen, has been announced for August 1956.

### Geographical Association: Annual Conference

The annual conference of the Geographical Association will be held in the London School of Economics, Houghton Street, London, W.C.2, during January 3–6, 1956. The presidential address, by Mr. L. S. Suggate, will be on "Aspects of Geography Teaching in Schools". In addition to the usual lectures, sectional meetings, excursions, etc., a joint meeting with the Royal Geographical Society and the Institute of British Geographers will be held in the former's premises in Kensington Gore, London, S.W.7, at which "Some Medical Aspects of Geography" will be discussed. Further information can be obtained from the honorary conference organizer, R. C. Honeybone, University of London Institute of Education, Malet Street, London, W.C.2.

The spring conference of the Association will be held at Brighton during April 3–7, 1956, and the programme and reservation leaflet for this meeting will be issued with the January issue of the Association's journal, *Geography*.

### Cloud Physics: Conference in London

A conference on "Cloud Physics", arranged jointly by the Physical Society and the Royal Meteorological Society, will be held in the Department of Meteorology, Imperial College of Science and Technology, London, S.W.7, during January 4–5. After an introductory talk by B. J. Mason (Imperial College) on the scope of cloud physics, the first half-day will be devoted to the atmospheric aerosol, with papers by C. Junge and H. Weickmann (both of the United States) on, respectively, the nuclei of atmospheric condensation and the constitution of non-precipitating clouds. For the remaining day and a half the microphysics of clouds will be considered, with papers by the following: B. J. Mason, R. Braham (United States), F. E. Ludlam (Imperial College), J. S. Marshall (Canada) and J. T. Wormell (Cambridge). The meeting will be open to non-members. Application forms, to be returned by December 15, can be obtained from Miss E. Miles, Physical Society, 1 Lowther Gardens, London, S.W.7.

### The Queen's University of Belfast

The following have been appointed to lectureships in The Queen's University of Belfast: Dr. R. J. Magee (inorganic chemistry), Dr. M. F. Grundon (organic chemistry), J. M. Gilchrist and Dr. W. F. K. Kerr (mechanical engineering), J. M. W. McBride (light electrical engineering), and Dr. D. S. McIlhagger (electrical engineering). The University has received the following grants: to the Department of Applied Mathematics, £2,250 from H.M. Treasury for a rocket research project with which the Department of Physics will be associated, and £1,200 in connexion with the International Geophysical Year; to the Department of Organic Chemistry, £500 a year from the Medical Research Council for work on branched-chain carbohydrates, and £450 a year from th British Empire Cancer Campaign for work on th synthesis of colchicine.

### Announcements

Sir Harold Roxbee Cox will deliver the twentiet Parsons Memorial Lecture at the Institution of Civ Engineers on December 13; he will speak c "The Development of the Gas Turbine".

Dr. E. J. Bourne, reader in organic chemistry i the University of Birmingham, has been appointe to the University of London chair of chemistr tenable at the Royal Holloway College in successio to the late Prof. Gwyn Williams.

The Massachusetts Institute of Technology ha appointed Dr. R. R. Doell and Dr. J. W. Winchest to be assistant professors in the Department c Geology and Geophysics. Their subjects are sei mology and geomagnetism, and nuclear geochemistr respectively.

The Meldola Medal, which is the gift of the Societ of Maccabæans, is being offered for award early i 1956 to the chemist who, being a British subject an less than thirty years old on December 31, 195 shows the most promise, as indicated by publishe chemical work brought to the notice of the Counc of the Royal Institute of Chemistry before Decembe 31. Communications should be addressed to th President, Royal Institute of Chemistry, 30 Russe Square, London, W.C.1, the envelope being marke "Meldola Medal".

Sir George Beilby Memorial awards, which ar considered at intervals by administrators representin the Royal Institute of Chemistry, the Society c Chemical Industry and the Institute of Metals, ar made to British scientific research workers, preferenc being given to investigations relating to the speci interests of Sir George Beilby, including fuel econom chemical engineering and metallurgy. In genera the awards are given to younger workers for origin investigations over a number of years. For award early in 1956, the attention of the administrator should be directed, before December 31, to ou standing work of the nature indicated, all commun cations being addressed to the Convener of th Administrators, Sir George Beilby Memorial Fun Royal Institute of Chemistry, 30 Russell Squar London, W.C.1.

A summer school on the applications of spectr scopy to chemical problems and on intermolecula forces and the properties of fluids will be held in th Department of Physical Chemistry, University c Cambridge, during August 18–25, 1956. Among th lecturers will be Prof. R. G. W. Norrish, Mr. R. I Bell and Prof. H. C. Longuet-Higgins. Full oppo tunity will be provided for discussions. Furthe information can be obtained from the Secretary c the Summer School, Department of Physical Chem istry, Free School Lane, Cambridge.

The Manchester and District Section of the Roy Institute of Chemistry is organizing an exhibition c laboratory apparatus and techniques with particula reference to instrumentation, to be held in the Ma chester College of Technology on January 4 (2–8 p.m and January 5 (10 a.m.–8 p.m.). Some thirty-fiv exhibitors are taking part, and there will be vario demonstrations (for example, glass-blowing an vapour-phase chromatography).

# INTERNATIONAL COSMIC RAY CONFERENCE

## MEXICO MEETING

SINCE the War, a series of international conferences on cosmic rays has been organized by the Cosmic Ray Commission of the International Union f Pure and Applied Physics. These conferences have een arranged at two-yearly intervals, the first being eld in Cracow in 1947, the second in Como in 1949, he third in Bombay in 1951, and the fourth in Bagnères de Bigorre in 1953. This last conference was almost exclusively concerned with the fundamental particle aspect of cosmic ray physics, although here was a small parallel meeting on time-variations f the cosmic ray intensity.

In contrast to the Bagnères de Bigorre meeting he topics chosen for the 1955 conference were the omposition and energy spectrum of the primary adiation, geomagnetic effects, variations of the ntensity with time and, finally, the problem of the rigin of the radiation.

The conference was held in Guanajuato, a beautiful ld Colonial town some 300 miles north of Mexico City, during September 5–13, and was made possible by generous grants from the Mexican Government and from Unesco. The meetings were held at the University of Guanajuato, where facilities were kindly provided by the rector, Lic. Antonio Torres Gomez. The detailed arrangements for the conference were made by Prof. M. S. Vallarta and the resident of the Cosmic Ray Commission, Prof. P. M. S. Blackett. In addition to some sixty cosmic-ay physicists working on the topics covered by the onference, a number of astronomers (Brown, Chandrasekhar, Gold, Kiepenheuer, Oort, Schluter, Unsöld and Van de Hulst) also attended, and the meeting provided a valuable opportunity for joint discussion of problems of common interest.

The first day of the conference was devoted to papers and discussion on the composition and flux of he primary radiation and on the influence of the earth's magnetic field on the intensity of the radiaion. Some recent work by the Iowa group was described which confirms the presence of a soft adiation in the auroral zone at altitudes greater han 50 km. It is believed that this radiation consists of electrons of rather low energy, which may belong to the high-energy tail of the auroral particle spectrum. The question of the abundance of lithium, beryllium and boron in the primary flux was discussed at some length, but the proportion of hese elements present is still in doubt. The results of a recent latitude survey carried out by the Chicago and Ottawa groups using shipborne neutron monitors and meson telescopes were reported. The position of he geomagnetic equator deduced from these measurenents appears to differ from that corresponding to he dipole field deduced from magnetic measurements, eading to an apparent discrepancy of as much as 7° n the geomagnetic latitudes of some stations.

The energy spectrum of the primary radiation was discussed on the second day. Data were presented by a number of workers on the low-energy end of the spectrum. In particular, the position of the knee in the intensity versus latitude curve was discussed; and evidence was presented showing that the position of the knee changes with time, being virtually absent at sunspot minimum, so that the intensity of the low-energy cosmic radiation was greatly increased at this time. The spectrum at high energies is deduced from measurements on large air showers, and several arrangements which are at present being used for the study of these showers were described. The radial density distribution of particles in showers of energy in the region of $10^{17}$ eV. has been investigated at Harwell and also by Russian workers using large counter arrays; some evidence was presented by the Harwell group for the existence of showers of energy $10^{19}$ eV. Some preliminary results were reported by the group from the Massachusetts Institute of Technology, which has recently completed a shower detector consisting of twenty large scintillator units. There was some discussion on the estimation of the primary-particle energy responsible for a given shower size, and there seemed to be general agreement among the different workers that the primary energy is given by the total number of particles in the shower multiplied by a factor of about $10^{10}$ eV.

The third and fourth days of the conference were taken up with the reporting and discussion of time variations of the cosmic-ray intensity. This session began with a discussion of meteorological effects on the sea-level intensity, in particular the relation between the intensity and atmospheric temperature. Then followed a series of contributions on the relation between the intensity and solar and geomagnetic activity. There were papers on cosmic-ray production associated with solar flares, intensity changes at the time of magnetic disturbances and the world-wide variation in the cosmic-ray intensity over the past solar cycle as recorded by the Carnegie Institution of Washington at a series of stations which have been in operation since 1936. Data from these stations show a variation in intensity during the solar cycle of about 4 per cent, maximum intensity occurring at the time of sunspot minimum. Discussion of the causes of these variations of intensity was mainly in terms of the possible effects of ejected solar material carrying magnetic fields out into interplanetary space, although there was no general agreement as to the precise way in which these fields produced the observed variations.

The fourth day was devoted to papers and discussion on the solar daily variation and its behaviour in relation to solar and geomagnetic activity, the sidereal daily variation and measurements on the isotropy of the high-energy particles producing large air showers. The anisotropy of the primary radiation in relation to the Sun, as evidenced by the presence of a solar daily variation, is well established; but as yet there is no general agreement on the existence of a sidereal daily variation. A new approach to the problem of the isotropy of the primary radiation at high energies lies in the measurement of the directions of arrival of large air showers, using techniques permitting an angular resolution of 5° or so. Some preliminary results of measurements of this kind were reported by the groups from the Massachusetts Institute of Technology and from the Imperial College of Science and Technology, London; but no definite anisotropy has so far been established with certainty.

The remaining time at the conference was allotted to contributions on theories of the origin of the primary radiation. This session began with introductory papers on the properties of the galaxy, the interstellar gas and the solar atmosphere. Prof. J. H. Oort described some recent work at Leyden confirming earlier results by Russian workers on the polarization of the light from the Crab nebula. The mean polarization over the central region of the nebula is 17 per cent; but there are indications that where a limited volume of the nebula can be isolated the polarization may be complete. Oort pointed out that it is possible to account for both the polarization at optical wavelengths and the observed intensity of radio noise if it is assumed that the emission is due to radiation from electrons of energy $\sim 10^{11}$ eV. spiralling in a magnetic field of $10^{-3}$ gauss. If this interpretation is correct, it opens up the interesting possibility that the Crab nebula may be a source of part of the cosmic radiation. The papers and discussion on the origin of the radiation left little room for doubt, however, that this problem still remains largely unsolved and is likely to feature as a subject for discussion at perhaps more than one cosmic-ray conference in the future.

The conference lasted for six days, and it will be appreciated that in a report of this length it has only been possible to mention a few of the many important contributions, selected in order to illustrate present trends in these fields.

---

# SECOND INTERNATIONAL SEAWEED SYMPOSIUM

FOLLOWING the suggestion put forward at the first International Seaweed Symposium, held in Edinburgh in 1952 (see *Nature*, 170, 478; 1952), the Norwegian Institute of Seaweed Research (Norsk institutt for tang-og tareforskning) arranged the second such symposium in Trondheim during July 14–16, when about a hundred and twenty scientific workers and industrialists from all over the world attended. In his opening address, Prof. Trygfe Braarud, chairman of the Board of Management of the Norwegian Institute of Seaweed Research, welcomed the delegates to Norway.

At the first session, dealing with "Algal Chemistry", Dr. E. E. Percival (Scotland) opened the proceedings with a paper on the polysaccharide sulphuric acid ester of the green alga, *Cladophora rupestris*, hydrolysis of which revealed L-arabinose, D-galactose, D-xylose, L-rhamnose and D-glucose, this being the first reported occurrence of arabinose in a seaweed polysaccharide; attempts to elucidate the structure of this complex polysaccharide by standard procedures were described. Dr. E. T. Dewar (Scotland) discussed the preparation, estimation and use of sodium laminarin sulphate as a heparin-substitute for preventing blood from clotting. The production of antibiotic substances by seaweeds was the subject of a paper by Prof. C. G. C. Chesters (England), in which certain littoral and sublittoral seaweeds have been examined for bacteriostatic activity; *Polysiphonia fastigiata* and *Halidrys siliquosa* are particularly good sources, and there is evidence of seasonal variation of antibiotic substances. The distribution of microbiological growth factors related to vitamin $B_{12}$, folic acid, folinic acid, niacin and pantothenic acid in the Rhodophyceae, Phaeophycea Chlorophyceae and Heterokontae was discussed b Prof. H. Lundin (Sweden) in a paper with L.- Ericson. The red and green algae generally contai higher amounts of vitamins than the brown alga the maximum $B_{12}$ content being possessed b *Vaucheria dichotoma* (2·8 μgm./gm. dry weight). Th origin of vitamin $B_{12}$ factors is believed to be th bacteria living epiphytically on the plant, the alga merely concentrating and storing the vitamin bu not synthesizing it. The carotene and carotenoi content of seaweeds was dealt with in two pape (by A. Haug and B. Larsen, and S. Liaaen and N. A Sørensen). Mr. Haug (Norway) discussed the caroten content of *Pelvetia canaliculata*, *Fucus vesiculosu* *F. serratus* and *Rhodymenia palmata*, the quantity i the fresh algae being generally much higher than i the dried materials and commercial seaweed meals drying and storing conditions are important factor in carotene breakdown. Prof. Sørensen (Norway dealt with the carotenoids of fresh *F. vesiculosus* an conditions leading to the formation of zeaxanthin it is now believed that this pigment is formed fro violaxanthin, and not fucoxanthin as originally suggested. Low-molecular carbohydrates were reviewe by Dr. B. Lindberg (Sweden), who has shown tha the mono- and di-β-D-glucosides of mannitol ar characteristic of many Phaeophyceae, while *P* *canaliculata* also contains the corresponding glucoside of D-volemitol; brown algae possess 'laminitol', *O*-methyl inositol. The glyceric acid – mannos glycoside of red algae is proved to be 2-D-glyceric aci α-D-mannopyranoside, while two recently isolate glycosides are floridoside-α-mannoside and 'iso floridoside' (1-glycerol-α-D-galactopyranoside). Th taxonomical value of these compounds was discussed

Dr. F. T. Haxo (United States), in a paper wit C. O hEochdha, reviewed the constituents of *Porphyridium cruentum*, a unicellular red alga which grow well but not prolifically in mineral-enriched sea water. The culture medium becomes viscous due t the presence of extra-cellular mucilage, which consist in part of a sulphated polysaccharide containin glucose, galactose, xylose and a uronic acid. Pigments include chlorophyll *a*, β-carotene, zeaxanthi and possibly lutein, while chromoproteins consist of phycoerythrin and two phycocyanins. Three pape (by D. B. Smith, A. N. O'Neill and A. S. Perlin S. T. Bayley; and W. Yaphe), read by Dr. E. Gordo Young (Canada), were devoted to the structure an degradation of carragheenin. By fractionation wit potassium chloride, this polysaccharide has bee separated into a potassium-sensitive fraction (*K*-carragheenin) and a potassium-insensitive fractio (λ-carragheenin); the former contains 3 : 6-anhydro-D-galactose and sulphated D-galactose residues i nearly equal proportions, while the latter appears t be mainly a sulphated D-galactose polymer. It i interesting to note that this anhydro-sugar in carragheenin is the enantiomorph of that present in agar Useful information on the structure of the tw fractions has been obtained by X-ray and infra-re studies. Bacteria capable of hydrolysing carragheeni and agar have been isolated from sea-water an marine algae; the cell-free enzyme solutions ar specific for the respective polysaccharides, and hav been used to identify agar and carragheenin in re algal extracts. Examination of the breakdow products should yield fruitful results.

Dr. Young, in a paper with D. L. Vincent and D. A. I. Goring, described the comparison of sodium alginate samples from different species by examination of optical rotation, viscosity, ionic mobility and sedimentation-rate; viscosity is still the best criterion of degree of polymerization. Mr. A. Jensen (with I. Sunde, of Norway) gave details of the quantitative determination of alginic acid in seaweed samples by decarboxylating the mannuronic acid residues with 19 per cent hydrochloric acid and measuring the carbon dioxide potentiometrically. The method is convenient for routine analysis and is claimed to be more accurate than either the titrimetric or colorimetric procedure. The qualitative detection of small quantities of alginates in food, cosmetic and other products is often a matter of some difficulty, and consequently great interest was shown in a new method demonstrated by Mr. R. H. McDowell (England), in which the small quantity of alginate present is converted to calcium alginate, and the invisible precipitate is then rendered visible as characteristic blue flocs by the addition of the dye, 'night blue'; by this means, as little as one part of alginate in a hundred thousand of solution can be detected. The detection of alginic acid in tissues by means of polarization optics was demonstrated in a series of slides by Dr. G. Andersen (Germany), whereby alginic acid, by virtue of its unique birefringent properties, is proved to occur in the middle lamellæ and primary cell-walls of the Phaeophyceae and is not accompanied by insoluble admixed 'hemicelluloses'.

The reaction of stearyl chloride on alginic acid was discussed by Mr. L. F. de Keyser (Belgium), the resulting ester being fractionated with ether to give the distearate and lower ester fractions. The seasonal variation in chemical composition of brown algae was the subject of papers by Mr. A. Haug (Norway) and Dr. C. Primo (Spain, read by Dr. J.-M. Perelló), and the results were compared with those of previous workers. The decomposition of alginates and laminarin by micro-organisms occurring on decaying seaweed and in maritime muds was discussed by Prof. C. G. C. Chesters (England), the techniques used for assaying 'alginase' and 'laminarinase' activity being demonstrated. The results of chemical investigation of the decomposition products should yield valuable information on the structure of these two polysaccharides. The economics of the large-scale production of mannitol and laminarin from aqueous extracts of *L. cloustoni* frond were examined by Mr. K. C. Reid (Scotland), who concluded that these two chemicals could be made available to industry at a reasonable price provided the weed residue was also processed for alginate. The drying of freshly harvested *L. cloustoni* was discussed by Dr. R. G. Gardner (Scotland, with T. J. Mitchell).

At the session devoted to the use of seaweed meals in human and animal nutrition, Dr. H. C. Wood (United States) read a paper (with G. L. Seifert) on *Macrocystis pyrifera* as a source of trace elements in human nutrition, and Mr. A. A. McInnes (Scotland) stressed the importance of seaweeds as a source of trace elements for cattle, pigs, poultry and sheep. Sales of seaweed meal in the world to-day show that the claims of the seaweed producers are in fact real, although it may be difficult to prove these claims experimentally. The results of feeding *Ascophyllum*, *Laminaria* and *Alaria* meals to chicks and laying-hens were discussed by Prof. J. Høie (Norway); in general, the introduction of 3–8 per cent of seaweed meal into a basal ration which did not include any riboflavin-rich compounds led to increased growth and improved health in chicks and better-egg laying and hatching in pullets, although similar effects were obtained by the addition of yeast and grass meal. The iodine content of the eggs was considerably higher in seaweed-fed hens, and this was dealt with in greater detail in papers by I. Sunde (Norway, read by Mr. B. Larsen) and Prof. C. Romijn (Holland). The addition of 1 mgm. iodine as *Ascophyllum* meal per hen per day increased the iodine content of the egg about twenty times, while 20 mgm. per day as *Laminaria hyperborea* meal gave a 150-fold increase. The iodine is concentrated in the water-soluble fraction of the yolk and not in the protein and lipoid fractions.

The botanical session was opened by Prof. Y. Yamada (Japan) with a paper on the distribution of *Sargassum* on the coast of Japan and its neighbouring regions, in which he said that the seventy known species of *Sargassum* can be divided into two types from the distribution point of view, and most of these are utilized as fertilizer. Prof. A. A. Aleem (Egypt) described his underwater studies on the ecology of *Macrocystis pyrifera* on the coast of California by means of the Cousteau–Gagnan aqualung, by which maps and surveys of the kelp beds were made and correlated with surface observations by aerial photography; this would seem to be a very successful method of studying sublittoral ecology, and is by no means confined to seaweeds. Prof. W. E. Isaac (South Africa) reviewed the species occurring in the Saldanha–Langebaan Lagoon, off the south-west coast of South Africa, in which *Gracilaria confervoides* is cast up to the extent of about a thousand tons a year and forms the basis of a small agar industry. Miss B. T. Chiu (Hong Kong) discussed the seaweeds of economic importance in south China, where the abundant *Sargassum* species are harvested for use as fertilizer and animal feedstuff, and many brown and red algae are used in human foods, medicine and the textile industry. Variations in the standing crop of *Laminaria cloustoni* have been observed for three areas off the coast of Scotland, and the significance of these survey results was dealt with by Mr. W. D. Richardson (with F. T. Walker, Scotland); in general, there was a decrease in seaweed growth between 1949 and 1953, but 1954 showed a recovery in two out of the three areas.

Dr. A. D. de Virville (France) stressed the importance, both from a scientific and practical point of view, of having an accurate distribution map of marine plants of industrial value, and outlined a plan for the cartographical survey of the resources of the French coast; the Fucaceae, Laminariaceae, Gigartinaceae and Zostereae are represented by different colours on the map, which then shows the location of these plants with a fair degree of accuracy. The paper by Miss C. MacFarlane (Canada) on studies in the seaweed populations of economic importance in Digby Neck area, Nova Scotia, was read by Dr. E. Conway (Scotland) and illustrated with many beautiful slides; seventy-five miles of the shore of the Neck and islands support sixty thousand tons of harvestable rockweeds, chiefly *Ascophyllum nodosum*, and *Gigartina stellata* and *Laminaria* beds are also extensive although tidal and topographical conditions make for difficult harvesting on most Fundy shores. Growth control in the Fucaceae and growth rings in stipes of *Alaria esculenta* were discussed by Dr. E. M. Burrows (England) and Dr. E. Baardseth (Norway), respectively, the latter also reading two papers (by H. Printz) dealing with the phenology and recolonization of *Ascophyllum nodosum*. During recent years reports have been received from various parts of the world that *Ascophyllum* is on the point of being exterminated due to its exploitation for seaweed meal, and this question of recuperation and recolonization aroused much interest among delegates; the best methods of harvesting this species were discussed in detail. Dr. H. Blackler (Scotland) discussed the time of reproduction and the rate of growth in certain Fucaceae, while Miss M. Naylor (England) dealt with the cytology of three British species of *Laminaria*, for which chromosome counts have been made both on the sporelings and the gametophytes. The resistance of *Gracilaria confervoides* to hydrogen sulphide was the subject of a paper by Mr. K. Stokke (Norway), who described experiments confirming the high resistance of the alga to this poison; the species was first recorded in Norway in 1935 and is frequently found in waters contaminated with hydrogen sulphide.

Many delegates contributed to the discussions following each paper, and it is hoped that the proceedings of the symposium will contain a résumé of these discussions together with the complete text of the papers presented. The meetings were held in the Norges Tekniske Høgskole, and three excursions were arranged in the Trondheimsfjord, when ample opportunity was given for studying the marine flora of the three localities. An excursion was also made to Molde and the west coast, and the delegates were able to view the coast at Hustad and to examine the littoral flora at Bud, where a delightful boat-trip was made to the archipelago of Bjørnsund.

It was unanimously agreed that similar symposia should be arranged in the future. Canada, France, Ireland and Spain were suggested as possible venues, and it was tentatively proposed to hold the third International Seaweed Symposium in Ireland in 1959 and the fourth in Spain in 1962. It was decided to appoint a standing committee to arrange the next Symposium.

E. T. Dewar

## SCIENTIFIC MANAGEMENT

A NOTE in the programme of the National Conference on Science and Management arranged by the British Institute of Management and held at Harrogate during November 2–4 reads: "So fundamental are the changes with which the scientists are confronting us at the moment that many people are already talking in terms of a second industrial revolution. At the same time it is obvious that the face of Britain cannot be changed overnight. The responsibility for transferring new knowledge from the research laboratory to the production floor must rest with management. The British Institute of Management has therefore chosen as the theme of its National Conference for 1955 'The Impact of Science on Management in the Future'."

The conference embraced a wide range of subject-matter. The 'impact' of the scientist was naturally most noticeable in the field of technology, and on the purely technical side managers had the opportunity of learning about such topical matters as the new materials and processes made practicable within the past few years and the uses and limitations of radioactive isotopes in industry. Discussion, however, was by no means limited to material and practical problems of production. The economics and the 'human implications' of technical innovation each formed the subject of a separate panel debate, while a further panel discussed the function of the research association.

Papers presented by individual speakers indicated how scientific techniques could be applied to such operations as retailing and the analysis of market trends, while spokesmen for such specialities as accounting, sociology and economics each in their turn found time to wonder whether their own particular contribution could truly be described as 'scientific'. Looming behind each topic and linking together the whole conference was one important basic question: to what extent is the function of management itself based on scientific principles? For most of the managers attending, this question did not represent a new consideration. In the course of a very full programme they received added confirmation and demonstration of the means whereby the scientist can make a valuable contribution to the everyday task of management in industry, commerce and local government.

In a paper circulated to delegates but unfortunately, due to illness, not delivered in person, Prof. George C. Homans, of Harvard University, underlined the value of the general approach of the scientist. "The practical value of any science", he said, "is that by making experience subject to explicit intellectual control it speeds up the learning process and so sets intuition and judgment free to work on new ground rather than old. In something as important as management, anything that even begins to get us free of empiricism, or to set empiricism free for new advances, makes a contribution." Prof. Homans was referring in particular to the contribution of the sociologist. In a paper on "Operational Research", Sir Charles Goodeve, director of the British Iron and Steel Research Association, had some more general remarks to make about the application of the scientific method to management's task of planning for the future. "Getting rid of illusions about science and scientists", he said, "is one of the first essential steps in the whole field of the application of science, whether on the technical or the operational side of industry." Curves and diagrams of all types should be critically examined before acceptance by people other than those who produced them. "I have seen many examples", said Sir Charles, "of managers being overawed by curves. This is a more dangerous attitude than that of the opposite extreme. You should copy the approach of the scientists and disbelieve anything you are told until you can independently come to the same conclusions. A scientist always asks questions and will never believe the answers he is told. He will not accept an authoritative answer and is always demanding experimental proof of at least some reliable observations. The scientist believes that managers can make better decisions if they have the facts and an objective appreciation of the effects of the various sources of action open to them. It might pay the manager to wait for the scientist to do all this if he does not take too long over it."

That most unscientific word 'automation', receiving its due measure of attention within the theme of the conference, proved to be less alarming in its implications than might otherwise have been suspected. Under the treatment of Mr. John Diebold, who had travelled from the United States especially to speak at Harrogate, the subject appeared indeed to be concerned with the same fundamental and stematic approach to management—in this case e management of production—as had been out- ded by Sir Charles Goodeve. "Automation", said r. Diebold, "is a way of thinking, a way of 'looking ' as much as a way of doing. It is an attitude—a hilosophy of production' rather than a particular chnology of electronic devices. It is something as volutionary in its way as Henry Ford's concept the assembly line. It is a very simple fact that the ost efficient use of machines has little to do with e most efficient division of human skills. Until cently, this was simply one of the paradoxes herent in mechanization. With the introduction the new concept and technology of self-regulating stems, it is no longer necessary to design the pro- uction processes around the limitations of human ills. It is here that we begin to reach the heart of e true meaning of automation."

John Diebold, who at the age of twenty-eight is escribed in the United States as 'the elder statesman automation', proved to be highly conscious of his are of the responsibility for introducing this word to general currency. It is not, he said, a very eautiful one, but he has yet to find any satisfactory bstitute for it. "For a long time", he added, "I have arched for a definition of automation that would be use to me in an operational way. In the course this conference I am sure we will all gain some ew insights into the problem. In the meantime, offer the following for your consideration: 'Auto- ation is a means of analysing, organizing and con- olling our production processes to achieve optimum e of all of our productive resources, mechanical nd material as well as human'."

The need for a scientific use of the machines which e scientists have provided was emphasized by Dr. . V. Bowden in a paper devoted to the electronic rocessing of data for management. More important an a machine's ability to do arithmetic, said Dr. owden, is its ability to organize its data. "How any managerial decisions", he asked, "rest on umerical criteria which may have been applied nsciously or unconsciously by the executives? ow many of them could be made by a machine?" isting many successful applications of electronic mputers to industry, Dr. Bowden had one very lling point to make. "We were once asked", he id, "to mechanize certain commercial calculations hich had occupied five people for about three weeks ery month. We found that the calculations could done on the Manchester machine in a couple of urs; but further study showed that they could done by hand in three hours if they were properly ganized and simplified in a manner which the athematician's analysis suggested. It is a very lutary experience", continued Dr. Bowden, "for y company which imagines that its accounting stem is simple and well understood by the staff to y to programme the work so that it can be done an accounting machine."

Besides the formulation of principles for the future, e conference was also concerned with the communi- ation of those principles not only to present-day anagers but also to those undergoing training for anagement. Education for management was one the most urgent issues discussed at Harrogate, d the problems of training managers in science and ientists in management received special attention two sectional meetings. Among those attending ere was a strong appreciation of the vital need for ore trained men in the future. This need was expressed very forcefully by Mr. R. Craig Wood in a paper entitled "The Influence of the Increasing Rate of Scientific Development on Future Management Requirements". "To make progress and succeed in the technological revolution", he said, "we will need more and better *human* management. We must upgrade our basic human material. There is no more exacting need for human management than in the development of the individual to new skills, higher abilities, greater responsibilities. The upgraded working force will need a higher level of management. Sheer technical brilliance will be no substitute for human leadership. . . . Mankind can enjoy the fruits of technical progress", concluded Mr. Craig Wood, "only so fast as it can learn to *manage* their production and distribution."

# PSYCHOLOGY AND THE FILM

A ONE-DAY conference on the film in training and research in psychology and psychological medicine was held in University College, London, on October 22. This conference, which was attended by about a hundred and fifty people, was organized by the British Universities Film Council, a body founded in 1948 to promote the production, distribution and use of films in university teaching and research, and which has already organized conferences on the film in relation to language teaching, to the teaching of arts-faculty subjects, and to chemical engineering. Section A of the conference dealt with films in psychology and Section B with films in psychological medicine, the morning sessions being devoted to films in training and the afternoon sessions to films in research. Although papers were read, a feature of the conference was the showing of a great number of films. This led to critical discussion on the individual films, as well as providing the most practical form of demonstration of the various functions films can fulfil.

At the commencement of Section A, Mr. A. Watson spoke of the danger of biased or false presentation through films; but, as conference members remarked during discussion, this danger is not peculiar to the film medium. A film on the cerebral cortex of the monkey was shown. Dr. M. Gunther then read a paper on babies' first feeding responses, using a film made by her and part of a film by Dr. Tinbergen on the pecking responses of a newly hatched gull. A film on cats reared in darkness, a subject which is of interest in connexion with miner's nystagmus, showed the rotations and oscillations of the eyes of cats. Another film, entitled "Warning in the Dark", showed that the capacity of some blind persons to avoid obstacles is due to their sensitive reaction to reflected sounds.

The Department of Psychology of the University of Reading has given some attention to problems of film presentation. Mr. D. Bruce, of the Department, in a paper entitled "Immediate Recall of Film Material", said that the film is suitable for memory experiments, because for these experiments meaningful, and consequently 'life-like', material is desirable, and also material the presentation of which is capable of exact repetition. He showed a film, "Fidelity of Report". Mr. S. Laner, of the same Department, is engaged in comparing the effectiveness of films with other visual media, as aids to learning. In his experiments he uses two versions of a film, and these were projected at the conference. One version portrayed the making of a paper barge with movement—in the normal film manner—and the other a series of static views at essential points in the operation. His experiments so far show the advantage of movement, and also of repeated film showings and of commentary. A coloured sound film, introduced by Dr. D. Fry, revealed movements of the tongue during speech of a surgical case whose cheek had been removed. It has been used in the teaching of students of physiology and of psychology, as well as phonetics.

Dr. D. Hill, presiding at the opening of Section B, said that little use has been made of films so far in psychological medicine teaching, and stressed again the need for specific objectives in teaching films. He asked conference members to consider whether films showing common or rare cases are the more valuable, and whether it might not be equally important to show the home as the clinical situation.

Dr. R. Mackeith introduced and provided commentary to the film "Hemispherectomy for Sturge–Weber Syndrome". This film, which was silent and coloured and the tempo of which (intentionally for teaching effectiveness) was slow, showed a child patient before and after hemispherectomy. The two films next projected were sound films, speech in them being an essential part of the portrayal; they were straightforward records of interviews of patients with a doctor: "Depressive states—1", and "Folie à deux". There was little change of point of view, and a minimum amount of expression through editing. In contrast, Dr. R. Spitz's film, "Grief", showing the condition of infants consequent on separation from their mothers, was the product of a high degree of selective editing.

In the afternoon Prof. P. Russell summarized the advantages of using films when studying behaviour. Films are permanent records; they facilitate measurement (including opportunity for deciding on appropriate measurements), the forming of hypotheses, and a complete analysis. A film "Function of Parietal Lobes" showed the behaviour of monkeys after lesions had been made; there was no loss of motor power of the monkeys, or of tactile discrimination, but impairment in learning from visual cues. Another interesting film—"Animal Studies in the Social Modification of Organically Motivated Behaviour"—showed the social behaviour of rats, in various circumstances of feeding. Dr. P. Sainsbury illustrated a paper on a method of measuring spontaneous movements by time-sampling motion pictures, by a film made in the course of research. A concluding paper on the use of the film as a thematic apperception test, by M. G. Cohen-Séat, of the Institut de Filmologie, Paris, was illustrated by some films made at that Institute.

The films shown at the conference illustrated the great variety of forms of record and of communication possible through cinematography. If the conference has led to an increased awareness of this, and therefrom perhaps of the value of research on the film itself, one useful purpose will have been served. Some of the films—in photography and matters of technical film detail—did not come up to the standards of the professional film-maker; but this can only emphasize the benefit which would result from better film-making facilities at universities and institutions where psychological films are made. The conference was well planned to show a number of ways in which the film can contribute to psychology training and research. Credit is due to the Britis Universities Film Council and to its representative Miss G. Keir and Mr. D. Bruce, who were responsib for the detailed arrangements. C. DENIS PEGG

# INTERNATIONAL RESEARCH IN RADIO ASTRONOMY

IN an account of a General Assembly of the International Scientific Radio Union held in Sydney i 1952 (see *Nature*, 171, 628; 1953), reference was mad to the fact that the Union had commenced th publication of some special reports on radio topic of international interest. During the past year, No 3, 4 and 5 in this series have been published wit the financial help of Unesco, and are obtainable fro the General Secretary of the Union, at 42 rue de Minimes, Brussels*.

These three reports, which deal with differen portions of the field of radio astronomy, have bee prepared by small sub-committees of expert researc scientists working in Australia, France, Great Britain the Netherlands and the United States, assisted b various members of the Union under the gener auspices of Commission V (Radio Astronomy), which Dr. M. Laffineur is the chairman.

Report No. 3 is entitled "Discrete Sources of Extra-Terrestrial Radio Noise", and comprises a clear summary of the considerable volume of research whic has been carried out, principally in Great Britain an Australia, since the inception of this field of work le than about ten years ago. The report deals in deta with the results of surveys of the distribution sources of radiation, the effects of the ionosphere i producing scintillation and refraction, the detectio of sources against background radiation and receive noise, and the determination of their positions an angular band-widths.

The fourth and fifth reports in the series are boun in one cover. No. 4 is entitled "The Distribution Brightness on the Solar Disk", and summarizes th progress made in this portion of radio astronomy sin the publication of Report No. 1 in 1950 under th more general title of "Solar and Galactic Radio Noise' The present report (No. 4) deals with the problem measuring the relative intensity of radio emissio from different parts of the solar disk, and the resul of observations carried out with receiving system operating at centimetre, decimetre and metre wave-lengths. These results are discussed in relation to study of the physics of the Sun, which has confirme in broad outline the conclusions drawn from optic observations concerning the solar atmosphere. Th radio work has, however, arrived at the stage providing more accurate estimates of electron tempe ature and density in the solar chromosphere an corona than have been available previously.

The exciting story of the prediction, and detectio seven years later, of radiation from hydrogen in inte stellar clouds on a wave-length of 21·1 cm. is discusse in cold scientific language in Report No. 5, entitle "Interstellar Hydrogen". A description is given of th mechanism of excitation of the hydrogen molecule, th measuring apparatus used, and the method of detern ing the distribution of hydrogen in the galaxy. he significance of the observations and the deduc-ions which may be drawn from them are briefly iscussed; and the report concludes with a list of the cientific institutions engaged in research on the 1-cm. line.

---

* International Scientific Radio Union. Special Report No. Discrete Sources of Extra-Terrestrial Radio Noise. Pp. 56; Belg. fr., 11s. 0d., or 1·5 dollars. Special Reports Nos. 4 and 5: T Distribution of Radio Brightness on the Solar Disk; Interstell Hydrogen. Pp. 72; 100 Belg. fr., 14s. 6d., or 2 dollars. (Brussel International Scientific Radio Union, 1954.)

All three reports contain a comprehensive, but elected, list of references to the specific portions of he field of radio astronomy to which they refer. he fact that they were prepared by small groups of nternational workers makes them invaluable to all ho are studying or pursuing research in this subject.

R. L. SMITH-ROSE

# BIOLOGY AND HUMAN AFFAIRS

CHANGES in educational thought and practice are usually so slight that they are scarcely disernible from one year to another; as time goes n they may build up into something formidable. wenty years ago, for example, the teaching of iology in British schools was on a small scale. In any girls' schools botany was thought to be the nly suitable biological subject, while in boys' schools otany was thought to be a subject suitable for girls, nd little, except a smattering of 'nature study', was aught.

In 1935 the British Social Hygiene Council (now he British Social Biology Council), a voluntary rganization formed originally to combat the venereal iseases, took the long view and turned to the ducational service as a means of giving children ational information about the workings of their own odies. It was expecting that actions based on this nowledge would lead to higher standards of health, nd was hoping that a deeper insight into biology ould endow men and women with a clearer appreiation of themselves as human beings; when ssociated with the understanding provided by the ther life sciences, this would form the basis for etter moral behaviour, particularly in relation to ex. The Council decided that its long-term objectives ould best be achieved by promoting and supporting he development of biology teaching in schools. ublic meetings were organized, as well as conerences, courses for teachers and summer schools. journal, then called *Biology*, was launched, and ow, under the name of *Biology and Human Affairs*, celebrating twenty years of uninterrupted pubcation.

During those twenty years changes in three ifferent directions have been accompanied by orresponding changes in the nature of the journal self. First, there has been a remarkable increase in he amount of biology teaching in schools. To-day he subject is taught in many grammar schools, and is becoming firmly established in secondary modern nd primary schools, although in some of these there a tendency to offer it only to boys, while girls are usy with domestic science. Secondly, there has been marked improvement in the content of the subjectatter. It is developing into a genuine natural ience, having depth as well as breadth; botany as been largely displaced by biology, a unified bject drawing its material and principles from oth plants and animals.

The third direction in which progress has been arked is in the field of sex education. From its ception in 1914 until it ceased to be a semi-official body in 1942, the British Social Hygiene Council's main function was to act as a central organization for public enlightenment in relation to venereal disease. It was with this object in mind that the Council embarked on a vigorous campaign in favour of sex-education. At first it met with bitter opposition, particularly from religious bodies and official organizations, and sometimes from the schools, while those most favourably disposed towards this new development but who were least able to make their views effective were the children themselves. Bit by bit, however, the opposition was won over, and when in 1943 the Ministry of Education issued its pamphlet on "Sex-Education in Schools and Youth Organizations" the campaign might be said to have achieved its object. It would, of course, be presumptuous for the founders of *Biology* to claim credit for all these advances; they deserve their proportionate share.

To-day, *Biology and Human Affairs* appears as the journal of an organization, the British Social Biology Council, which is committed to promote and encourage the teaching of human biology as a cultural and practical subject; to preserve and strengthen the family as the basic social unit; and to encourage the dissemination of biological knowledge as a means of emphasizing the social responsibilities of individuals, the implications of population problems, the removal of conditions conducing to promiscuity, the elimination of commercialized vice, and a reduction in the incidence of social diseases, particularly the venereal diseases. The contents of its anniversary number indicate the broad catholic way in which those responsible for the production of the journal are seeking to implement the aims of its parent body. Articles include one on the adaptation of farm animals to their environment, by Dr. John Hammond; the fauna of built-up areas, by Dr. E. J. Popham; the natural history of the 'spiv', by Dr. P. D. Scott; the breeding behaviour of toads; a progress report on poliomyelitis; and the adventures and vicissitudes of a laboratory technician, by F. C. Taylor, senior laboratory steward at Eton College.

# HOSPITAL IN-PATIENT STATISTICS IN ENGLAND AND WALES

AS part of the Registrar General's statistical review of England and Wales for the two years 1950–51, a "Supplement on Hospital In-Patient Statistics" has been published* which makes available a fresh selection of material from a hospital in-patient inquiry started in 1949. The chief purposes of the inquiry were to assist hospital administrators by a more detailed analysis of the diseases treated and the types of patients involved; and also to increase the information available about the general pattern of ill-health in the community obtainable from mortality and morbidity data. Since the inquiry has, up to the present, been largely experimental, it has covered only a proportion of hospitals; and, moreover, different selections of tables are presented for the several years analysed. Sufficient experience has now been gained to put the project on a more permanent and comprehensive basis.

---

* The Registrar General's Statistical Review of England and Wales for the two years 1950–51: Supplement on Hospital In-Patient Statistics. Pp. iv+151. (London: H.M.S.O., 1955.) 7s. 6d. net.

Attention is focused in this supplement on the patients' length of stay in hospital, and a variety of different types of analysis have been made involving various cross-classifications by hospital group, diagnosis, sex, age and social class. Admissions for childbirth and diseases of pregnancy have been excluded from the main tables; but a separate analysis of length of stay according to birth-weight is provided. There is also one appendix listing the participating hospitals with an age-and-sex distribution of discharges; and another giving the same type of distribution for patients actually in National Health Service hospitals on the night of the 1951 Census.

It is particularly gratifying to a statistician to see emphasis being laid on statistical frequency distributions as opposed to mere averages. Theoretical studies of fluctuations in waiting-lists, for example, are dependent on knowing the actual form of the distribution of length of stay. Again, variations in the latter with district, social class, the elapse of time, etc., are also of clinical importance. One curious point in connexion with the grouping of the frequency distributions is perhaps worth directing attention to. In Table 2, for example, the grouping is by single days up to 20, and then in tens up to 100, with coarser grouping in the tail. This seems quite reasonable and enables one to see the general shape of the curve at a glance. Tables 5 and 6, on the other hand, employ two different arrangements, each involving a mixture of intervals grouped in 1, 2, 3, 4, 7, 21, etc., days. Although one cannot say that this is wrong, a more uniform presentation would certainly make the tables easier to use and interpret.

It is, of course, most valuable to have this material on the distribution of length of stay, especially as it may be more comprehensive in future. At the same time, it must be pointed out that much more than this is required by administrators using hospital statistics to gauge the efficiency with which the demand for in-patient care is being met. Valid conclusions have to be based on considering several inter-related items, including bed allocation, bed occupancy, turnover interval, discharges and deaths (or admissions), and waiting lists as well as length of stay.

# ROCKEFELLER FOUNDATION AWARDS

Among the grants recently made by the Rockefeller Foundation, New York, are the following:

## Royal Institution, London, and Cavendish Laboratory, Cambridge

An award of 30,300 dollars has been made to the Davy Faraday Laboratory of the Royal Institution and one of 40,000 dollars to the University of Cambridge for the Medical Research Council's Unit in the Cavendish Laboratory, to aid the researches on proteins at these centres.

It is now more than twenty years since Prof. J. D. Bernal and Dr. D. Crowfoot announced in *Nature* that they had obtained X-ray diffraction photographs of a protein crystal. To interpret these photographs and get information about the structure of molecules which contain thousands of atoms has for long seemed a task of such complexity that one could scarcely hope for success. Quite recently, however, the most formidable obstacle has bee overcome. M. F. Perutz has shown that heavy atom or groups can be attached at definite places in th hæmoglobin molecule without disturbing the crysta line structure, and that by measuring the consequen changes in the intensity of diffraction, the phases c the reflexions can be determined and the structur computed. This opens up a vast new field for cryst analysis which is now being explored at a number c laboratories. New ways of attaching heavy group to various parts in the molecule are being discovered and these groups can be located. A beginning can b made in the task of mapping out the positions in th molecule of certain amino-acid residues or othe groups, and eventually of linking them up by th intervening structure.

The Unit at Cambridge, under Dr. M. Perutz an Dr. J. C. Kendrew, and the group at the Dav Faraday Laboratory under my direction are workin in complete collaboration on these problems, studyin in particular the structures of hæmoglobin and myc globin. Quite apart from the new insight which wi certainly be gained into the part which these mole cules play in living matter, the solution of th technical problem of applying X-ray analysis to suc vast molecules is very thrilling indeed.

Lawrence Bragg

## Chemical Crystallography Laboratory, Oxford

Over the past twenty years I have been intereste in the possibility of using X-ray crystallographi methods to find the arrangement of the atoms i protein molecules and particularly in insulin. One c many possible approaches to solving this proble seems to be the crystallographic study of naturall occurring peptides such as the gramicidins an tyrocidine or oxytocin and vasopressin. These al have molecules much smaller in size than even th smallest protein molecules; some indeed are smalle than vitamin $B_{12}$, of which we have already found i possible to obtain the kind of information we require

Dr. R. L. M. Synge has accordingly prepared fo us a series of heavy-atom derivatives of gramicidin and we are now making some progress with th detailed X-ray analysis of one group of these. W already have evidence that there may be a connexio between the way the peptide chain is folded i gramicidin *S* and the way it is folded in part of th molecule of insulin. But even if later we find tha the connexion in chain configuration is less close tha we at present suppose, we think that the atomi arrangement in these peptide molecules is itsel of great interest and some importance. Paralle with the work on peptides, we are beginning agai to examine the crystal structure of insulin in th light of Dr. Sanger's evidence of its chemical structure

The present grant from the Rockefeller Foundatio (£3,000, during a three-year period) is the renewal c a grant made to me over a number of years fo research assistance in connexion with these problems

Dorothy Crowfoot Hodgkin

## Department of Chemical Pathology, St. Mary's Hospital Medical School, London

A grant of £4,600 has been made to the Universit of London for the purchase of special equipment suc as a 'Spinco' preparative ultracentrifuge and a electrophoresis apparatus by the Department c Chemical Pathology at St. Mary's Hospital Medic school. This Department has only been created this year, and I am the first holder of the chair. My ecent interests have centred on the chemistry and metabolism of proteins and the biogenesis of porphyrins, and it is expected that the work of the new Department will largely proceed along the lines mentioned. In the protein field, studies on the whole animal with the aid of isotopically labelled aminocids will be supplemented by investigations on *in vitro* systems, particularly relevant enzymes. Of pecial concern to the Department will be the proteins f connective tissue, and in this connexion the ynthesis of collagen will receive close attention.

In the porphyrin field the main pathway of synthesis seems reasonably well established; but the enzymes responsible for the various steps are still largely unknown, and further research in this field is likely to yield interesting results.

A. NEUBERGER

### Department of Zoology, University College, London

The grant of £2,700 made to me is for the purchase of a single piece of apparatus, namely, a 'Spinco' preparative vacuum ultracentrifuge, and it will be used for the preparation and analysis of various tissue fractions in connexion with the work of R. E. Billingham, L. Brent and myself on the mechanism of transplantation immunity.

P. B. MEDAWAR

# RADIOLYSIS OF LIQUID *n*-HEXANE AND SOLUTIONS OF ANTHRACENE IN *n*-HEXANE

By Dr. F. H. KRENZ

Department of Natural Philosophy, The University, Edinburgh

A STUDY has been made in this laboratory of the radiolysis in vacuum of pure, liquid *n*-hexane and of solutions of anthracene in hexane by γ-rays from a cobalt-60 source. The principal products of the radiolysis of the hexane were hydrogen, methane, ethane and an unsaturated hydrocarbon with approximately the same volatility as *n*-hexane. $C_3$- and $C_4$-hydrocarbons were also detected, but in amounts which were negligible compared with hose of the principal products. A $C_5$ fraction was never satisfactorily separated from hexane, but did not appear to contain any important product.

Hydrogen, methane, ethane and the unsaturated iquid hydrocarbon were formed in amounts which were directly proportional to the energy absorbed rom the γ-rays up to the highest concentrations of products measured (*c.* $10^{-4}$ *M*). The yields, *G*, in erms of the molecules of products per 100 eV. of γ-ray energy absorbed by the hexane (determined by errous sulphate actinometry, using $G_{\mathrm{Fe}^{3+}} = 15\cdot5$) were:

$$G_{\mathrm{H}_2} = 4\cdot89 \pm 0\cdot2 \qquad G_{\mathrm{C=C}} = 4 \pm 2$$
$$G_{\mathrm{CH}_4} = 0\cdot41 \pm 0\cdot1 \qquad G_{\mathrm{C}_2\mathrm{H}_6} = 0\cdot69 \pm 0\cdot1$$

The radiolysis in vacuum of solutions of anthracene n hexane showed that anthracene in concentrations p to $10^{-3}$ *M* had no measurable effect upon the yields of hydrogen, methane or ethane, but caused a iminution in the yield of unsaturated products. $G_{\mathrm{C=C}}$ decreased with increasing anthracene concentration toward a minimum value of approximately 2. The radiolysis of the solutions was accompanied by fading' of the anthracene absorption spectrum. The bands between 300 and 380 mμ gradually disappeared, nd were replaced by a new spectrum between 200 nd 280 mμ, superimposed upon the very intense nthracene band at 256 mμ. The new spectrum losely resembled that of dianthracene (Weiss, J., rivate communication; I am indebted to Dr. Weiss or the absorption spectrum of dianthracene in thanol). $G_{-\mathrm{A}}$, the number of anthracene molecules isappearing per 100 eV. of γ-ray energy absorbed y the hexane, was described within the experimental rror by the function:

$$G_{-\mathrm{A}} = 3\cdot6 \left\{ \frac{3 \times 10^3 M}{1 + 3 \times 10^3 M} \right\}$$

where *M* is the concentration of anthracene in moles per litre.

The results above are explained by a simple mechanism resembling that which has been established for the mercury-photosensitized photolysis of paraffin hydrocarbons in the gas phase[1]. The principal primary step in the radiolysis of hexane is considered to be

$$R\mathrm{H}^* \rightarrow R\cdot + \mathrm{H}\cdot \qquad (1)$$

$R\mathrm{H}^*$ represents an electronically excited molecule of hexane resulting from primary absorption processes[2], $R\cdot$ a hexyl radical and H· a hydrogen atom formed by the rupture of a C—H bond in hexane. The rupture may impart considerable kinetic energy to the fragments, particularly to H·, which probably reacts immediately with the surrounding hexane:

$$\mathrm{H}\cdot + R\mathrm{H} \rightarrow \mathrm{H}_2 + R\cdot \qquad (2)$$

The hexyl radical must disappear, in the absence of competing reactions, by

$$R\cdot + R\cdot \rightarrow R_2 \qquad (3a)$$

or

$$R\cdot + R\cdot \rightarrow R\mathrm{H} + R_= \qquad (3b)$$

$R_2$ is the dimer, dodecane, and $R_=$ is an unsaturated compound formed by the disproportionation of two hexyl radicals, that is, it is one of several possible isomeric hexenes.

The relatively small amounts of methane and ethane found among the products may result from (*a*) the primary rupture of a C—C bond in $R$H, (*b*) H· atom 'cracking' of hexane[3] as an alternative to reaction (2), or (*c*) dissociation of an excited radical produced in the primary step (1). The methyl or ethyl radicals so formed probably undergo reactions analogous to (2), forming methane and ethane respectively[4]. The reason for the relative unimportance of processes of this type is not apparent.

In solutions of anthracene, reactions (3*a*) and (3*b*) must compete with the following reaction:

$$R\cdot + A \rightarrow RA\cdot \qquad (4)$$

Here $A$ represents a molecule of anthracene, and $RA\cdot$ is a new free radical resulting from the addition of $R\cdot$ to $A$, probably at the 9- or 10-position. $RA\cdot$ may react with a second $R\cdot$ to form $RAR$, or may form a dimer analogous to $R_2$, namely, $RAAR$. In either case a stable product is formed having an electronic structure similar to that of dianthracene.

The results summarized above are in substantial agreement with the results of earlier studies of the radiolysis of paraffin hydrocarbons[5], and the theory successfully describes the earlier results. The yield, $G_R$, of free hexyl radicals given by the theory is

$$G_R = 2\,G_{H_2} + G_{CH_4} + G_{C_2H_6}$$
$$= 10\cdot 9$$

On the same basis, the yield of radicals of all kinds (excluding H· atoms) is at least 12. These values are in agreement with values of $G_R$ ranging from 9·9 to 14·3 recently found by Magat and co-workers[6] for *n*-heptane, *n*-octane and *cyclo*hexane, using an independent method of measurement.

More recently, Schuler and Allen[7] have noted th the yield, $G_{H_2}$, of hydrogen from liquid *cyclo*hexa decomposed by energetic radiation was independen of the linear ion density of the radiation. Such a effect is explained in terms of reactions (1) and ( above, since the separation between successive io izations (or excitations) would have to be of molecul dimensions before recombination of atoms coul compete effectively with reaction (2).

A complete account of the present work has bee submitted for publication in the *Canadian Journal* *Chemistry*. I am grateful to Prof. N. Feather f support and encouragement and to Drs. N. Mill and R. A. Back for much help and advice in th course of the work.

# NUCLEUS AND CYTOPLASM IN CELLULAR INHERITANCE

By PROF. J. F. DANIELLI, DR. I. J. LORCH, DR. M. J. ORD and MISS E. G. WILSON

Department of Zoology, King's College, London, W.C.2

THE relative importance of nucleus and cytoplasm in cellular inheritance is uncertain. We have studied this problem by transferring nuclei of one species of *Amoeba* into the cytoplasm of another species. In such heterotransfers the resultant animal usually lives for up to a month, may undergo a number of divisions, and very occasionally will give rise to a clone of animals of viability and vigour comparable with the parent animals. We have previously reported on the characters of heterotransfers for the first month after the transfer operation. In this period the characters follow the cytoplasmic type closely, although some influence of the nuclear species can be detected[1]. The present report is concerned with a study, over a period of six years, of a heterotransfer clone which originated from the transfer of an *Amoeba proteus* nucleus into the cytoplasm of an *Amoeba discoides*. This clone is known as $\overrightarrow{P_nD_c}(1)$. Similar studies are in progress with other heterotransfer clones, but are not sufficiently advanced to warrant present reporting.

The characters studied fall into three groups: (1) observations made on individuals taken from mass cultures of $\overrightarrow{P_nD_c}(1)$; (2) observations made by transferring nuclei from $\overrightarrow{P_nD_c}(1)$ to cytoplasms of clones similar to the parent clones, and by replacing the nucleus in $\overrightarrow{P_nD_c}(1)$ amoebae with a *proteus* or *discoides* nucleus from clones similar to the parent clones; (3) observations on antigens.

Quantitative measurements of the following characters were made on individuals taken at random from mass cultures: shape when moving; average nuclear diameter; frequency distribution of nuclear diameters; division rate. As shown in Table 1, th shape of the animals when moving is intermediat between the shapes of the two parent species. O the other hand, the nuclear diameter, the frequenc distribution of nuclear diameters and the rate c division are very much more like those of the cyto plasmic parent than like the nuclear parent. Th shape when moving and the two nuclear character were measured about three months after this clon was first obtained, in 1949, and have been re-measure at intervals of a year or less. Over this period of si years there has been no change in these character outside the limits of experimental error.

When the nuclei from individuals of $\overrightarrow{P_nD}$ (1) ar back-transferred to *proteus* cytoplasm ($P_c$) or *discoide* cytoplasm ($D_c$), it is possible to make quantitativ observations of the frequency of reactivation as we as of the other characters. When an *Amoeba* i enucleated it tends to round up and become covere with small short blunt pseudopodia. When renucleate successfully the *Amoeba* resumes amoeboid movemen with a concomitant change of shape: it is this retur to normality which is termed reactivation. Nucle from $\overrightarrow{P_nD_c}(1)$ reactivated $P_c$ and $D_c$ equally well. O the other hand, when the frequency of divisions an the probability of clone formations were observed the behaviour of these individuals after reactivatio was more like that which would have been foun after renucleation with $D_n$ than with $P_n$. Thus, afte a long sojourn in *discoides* cytoplasm, *proteus* nucle are modified so as to resemble *discoides* nuclei i some respects. When the cytoplasm of individual from the clone $\overrightarrow{P_nD_c}(1)$ was renucleated with $P_n$ o $D_n$, the cytoplasm behaved more like *discoides* tha

Table 1

this table the various characters of the culture $\overrightarrow{P_nD_c}(1)$ are com-
red with the same characters in the parent species $P_nP_c$ and $D_nD_c$

| Division | | + | |

ke *proteus* cytoplasm. Although this was so, there as a considerable difference between cytoplasm om $\overrightarrow{P_nD_c}(1)$ and cytoplasm from the original *iscoides* clone, especially so far as frequency of lone formation was concerned.

The general conclusions which may be drawn from he ten morphological and physiological characters eported in Table 1 are: (*a*) that after six years the ytoplasmic influence on all these characters is always s strong as the nuclear influence, and for most haracters the cytoplasmic influence is very much ore pronounced, and (*b*) both nucleus and cytolasm have changed to a significant degree. The egree to which these changes in nucleus and in ytoplasm are reversible has yet to be investigated.

Over the past eighteen months we have studied he reactions of $\overrightarrow{P_nD_c}(1)$ to cytolytic antisera prepared rabbits. It is usually supposed that cytolytic ntisera cause specific cytolysis by combination of ntibody with antigen in the plasma membrane. ntisera prepared to *discoides* and *proteus*, respectely, are specific for the species to which they are repared. When an *Amoeba* is placed in a dilute olution of a toxic antiserum it takes up a shape haracteristic of the amoeba species, becomes imobilized and in sufficiently concentrated antibody ill ultimately die. In lower concentrations of antiody the animal may recover, feed and divide. In able 1 is recorded the behaviour of $\overrightarrow{P_nD_c}(1)$ in ntisera prepared from *A. proteus* and from *A. iscoides*. We have measured the toxicity (determined y the proportion of animals killed after twenty-four ours exposure to dilute antiserum), the shape of nimals in antiserum and rate of division after covery in antiserum. In five out of six characters udied with antisera, the influence of the nuclear pecies is far greater than that of the cytoplasmic pecies. Thus the surface antigens, that is, some of e macromolecules making up the surface of an moeba, have characters at the macromolecular level hich are mainly determined by the nuclei.

The general outcome of this study of sixteen characters is that, whereas there is a strong predominance of cytoplasmic influence determining morphological and physiological characters, there is an equally strong predominance of nuclear influence determining antigenic, that is, macromolecular, characters. From the time of the original heterotransfer to the most recent measurements summarized in Table 1, the clone $\overrightarrow{P_nD_c}(1)$ had undergone not less than five hundred consecutive cell divisions, so that the molecules present in the original heterotransfer have been diluted by a factor of the order of $2^{500}$. On the average the amoebae which now constitute this clone cannot contain even one molecule of the proteins, nucleic acids or polysaccharides which were present in the original nucleus and cytoplasm at the time of heterotransfer. Consequently, it is impossible to explain even a modest degree of persistence, at the present time, of either nuclear or cytoplasmic traits by the passive carry-over of macromolecules from the original nucleus and cytoplasm. All persistent characteristics which are now present in this clone must be present as a result of often repeated duplication.

We cannot here set out the numerous alternative hypotheses with which the facts reported above are compatible. The hypothesis which appears to us to be the most interesting to investigate is that the nucleus determines the specific characters of the macromolecules which are present in a differentiated cell, whereas the organization of these macromolecules into functional units depends to a very marked degree upon cytoplasmic inheritance. The nucleus may exert its influence in a variety of ways: for example, the actual synthesis of antigenic macromolecules may be nuclear, or the nucleus may supply to the cytoplasm complex enzymic units which carry out syntheses of macromolecules in the cytoplasm, or the nucleus may provide some other active unit, possibly pentose nucleic acid, which can leave a nuclear imprint upon the products of cytoplasmic synthesis, etc. This hypothesis, like most other hypotheses which might be advanced to account for the distribution of nuclear and cytoplasmic inheritance, does not account directly for the fact that nucleus and cytoplasm interact and change one another.

The amoebae used in these studies have been kept, so far as possible, in constant environmental conditions. We have evidence that discontinuous changes may take place in some of the characters we have studied as a result of variation in environmental conditions.

We must add that undue importance should not be attached to observations on one heterotransfer clone. Most heterotransfers do not become stabilized and give rise to clones, and despite much painstaking study we cannot yet define the circumstances which decide whether a heterotransfer will become stable. A variety of other heterotransfer clones must be studied before we can tell whether the results summarized in Table 1 are typical. Additional heterotransfer clones are now being investigated; but it will be a number of years before the complete picture is established.

*Note added in proof*. Serological studies of a second interspecific clone have now been obtained which agree closely with those reported on $\overrightarrow{P_nD_c}(1)$.

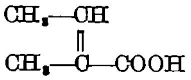
## Configurations of Tiglic and Angelic Acids: an X-Ray Determination

PROF. S. STENHAGEN recently directed our attention to the need for a direct determination of the configurations of tiglic and angelic acids, because in recent synthetic work on certain 2-methyl-alkenoic acids the assignment of geometrical configuration has been based primarily on the correlation of their spectral data with those of the simplest acids of the series, tiglic and angelic.

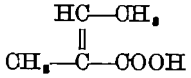
Tiglic acid has generally been assigned the *trans*-configuration (*cis*-methyl) mainly from a study of the rates of esterification of tiglic and angelic acids under similar conditions[1], and from a comparison of the physical properties of these acids with the *cis*- and *trans*-crotonic acids[2]. This evidence is certainly indirect; but more conclusive chemical evidence has recently been obtained by Dreiding and Pratt[3] from a study of the carboxylation of *cis*- and *trans*-2-butenyl lithium, a reaction which is considered to afford a stereospecific synthesis of tiglic and of angelic acid.

Although the combination of all the above evidence may be regarded as conclusive, we still felt that it was desirable to attempt a completely direct determination of the structures of these acids by the method of X-ray crystal analysis. This has now been carried out. In the case of tiglic acid, all the atomic positions have been ascertained with considerable accuracy (see Fig. 1) and the results establish the *trans*-configuration, with the doub bond in the α–β position of the butenic acid chain



$$\begin{array}{l} CH_3\!-\!CH \\ \phantom{CH_3-}\| \\ CH_3\!-\!C\!-\!COOH \end{array}$$

Our work on angelic acid is not yet complete; bu the results so far obtained are sufficient to show quit conclusively that this acid has the expected ci configuration:



$$\begin{array}{l} \phantom{CH_3-}HC\!-\!CH_3 \\ \phantom{CH_3-}\| \\ CH_3\!-\!C\!-\!COOH \end{array}$$

Crystals of tiglic acid are triclinic, with $a = 7{\cdot}7$ $b = 5{\cdot}23$, $c = 7{\cdot}42$ A. (all ± 0·02 A.), $\alpha = 96$ $\beta = 87{\cdot}7°$, $\gamma = 74{\cdot}5°$ (all ± 1°). The volume of th unit cell is 286 A.$^3$ and it contains two molecul (density observed, 1·163, calculated 1·162). Th space group $P\bar{1}$ has been assumed, with the cent of inversion between the carboxyl groups of tw molecules hydrogen bonded to form a symmetrica dimer. On the basis of these assumptions, the prob lem was attacked by the molecular Fourier tran form method, with projections along the short $b$-axi The transform evaluated for the *cis*-molecular stru ture could not be fitted to the weighted recipro lattice net; but with the *trans*-structure an excellen fit was soon obtained. The phase constants of th ($h0l$) structure factors obtained by this process enable an electron-density projection to be evaluated. Aft several refinement processes, the map shown in Fig. was obtained, with all the carbon and oxygen atom clearly resolved.

This projection is consistent with a coplana structure and with bond-lengths and valency-angle

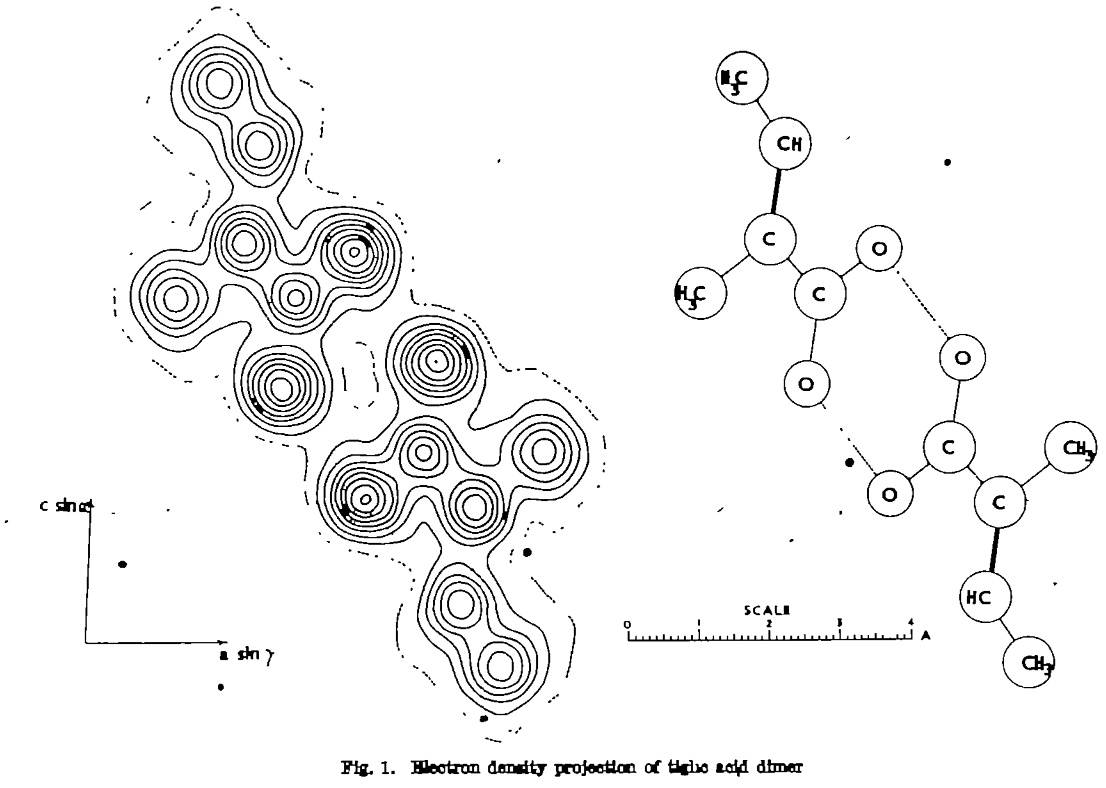


Fig. 1. Electron density projection of tiglic acid dimer

the expected magnitudes, except that there is some idence of repulsion between the methyl groups tached to the α- and β-positions. The β-methyl oups at the extreme ends of the picture appear o be somewhat displaced in position. Whether the hole structure is accurately coplanar or not must wait a more accurate evaluation of the third co-dinates of the atoms, which are perpendicular to is projection plane. In the meantime, it may be oted that difference syntheses based on this pro-ection indicate clearly the number of hydrogen toms attached to each carbon and thus show that e double bond is in the α–β position and not in the de-chain.

## The Free Amino-Groups of Soluble Feather Keratin

FEATHER keratin can be made soluble by extraction ith urea and reducing agents or by oxidation with erformic acid, and it has been shown that the esulting solutions contain particles with a small istribution of weight and charge and a molecular eight of 10,000[1,2]. Rougvie[3] oxidized feather eratin directly with peracetic acid and similarly ound the soluble particles to have a molecular weight f 10,000. He also made the important observation hat fibres reconstituted from the oxidized material ave X-ray diffraction patterns with much of the etail of those of the original feather.

This communication is concerned with the results f an end-group analysis of oxidized feather keratin ysteic acid – keratin) prepared according to the ethod already described[2]. The interpretation of the nd-group analysis of other keratins has been difficult ecause the molecular weight of the reacting material as not been known. We do not have this complication in the case of feather keratin.

After reaction of cysteic acid – keratin with fluoro-initrobenzene (24 hr. in 50 per cent ethanol and per cent sodium bicarbonate) and subsequent ydrolysis in 5·8 $N$ or 12 $N$ hydrochloric acid, the initrophenyl derivatives of aspartic acid, serine, reonine, glutamic acid, glycine, alanine and valine an be detected; ε-dinitrophenyl lysine is also resent. However, the total amount of α-dinitro-henyl amino-acids corresponds to only 0·1 equiva-nts/mole of protein, and similarly the concentration f dinitrophenyl lysine is 0·1–0·15 mole/mole protein. oupling of cysteic acid – keratin with fluorodinitro-enzene, in 2 $M$ guanidine in 50 per cent ethanol, r in aqueous solutions at pH 11·5, gives a similar roduct to this. Traces of dinitrophenyl amino-acids n also be found in the ether extract of the acidified initrophenyl-keratin before hydrolysis, and it is ossible that the few end-groups result from degrada-on during coupling.

Cysteic acid – keratin, treated with cation and nion exchange resins to remove small ions, combines with less than 0·2 equivalent hydroxyl ion/mole protein between pH 6 and 8·5. Between pH 8·5 and 10·5, 0·2 equivalents of $OH^-$ ion are bound by each mole of protein. Hence few ε-amino-groups of lysine, α-amino-groups or imino-groups in each protein molecule are available to the hydroxyl ion.

The molecular weight of cysteic acid – keratin is known unambiguously and the gross composition is consistent with the absence of a non-protein prosthetic group, so the failure of the α-amino-groups to react with hydroxyl ion or with fluorodinitrobenzene is evidence that the protein has a cyclic structure.

## Electron Microscopic Observation of Monolayers of Synthetic Linear Polymers

WHEN monolayers of some synthetic linear polymers at air/water interfaces are compressed to less than a certain area, bright streaks can be observed under dark-field illumination[1]. Subsequent compression gives rise to tiny visible striations running across the width of the trough and finally produces fibrous threads which can be picked up from the water surface. Since little is known about the structure of these heterogeneities, we have carried out an electron microscopic examination of spread films of synthetic polymers, and obtained, especially in the case of nylon, interesting pictures exhibiting the structure of the spread films.

A sample of 6-nylon (poly-ε-capramide, *D.P.*153) was spread from its mixed solution in benzene–phenol (3/1 v/v) on the surface of distilled water in a Langmuir trough. The uncompressed and compressed films were transferred to a collodion support by using a lifted film technique[2] for building up films on a slide. They were then shadow-cast with chromium at an angle of 12° to the surface and examined in a Hitachi *HS*-II type electron microscope. Micrographs are shown in Figs. 1 and 2. A blank water sample, which was transferred from the trough to a collodion support, is shown in Fig. 1,*a*.

When 6-nylon films were initially spread at an area of 80 A.$^2$/monomeric unit, unspread material was seen in the form of winding microfibrils (Fig. 1,*b*). The mean microfibrillar thickness was estimated to be 30 A. from the width of the shadow. The bare portions may contain film molecules that are less densely packed. When compressed to 30 A.$^2$/monomeric unit, the film produced a large number of microfibrils oriented approximately at right angles to the direction of compression and linked together to form a network (Fig. 1,*c*). This network may account for the elasticity which had been found with these films[3]. Further compression to 2 A.$^2$/monomeric unit brought about visible striations on the films. The film structure in this region exhibited an

(a) Blank, no film, magnification 13,500; (b) uncompressed films at 80 A.$^2$, magnification 13,500; (c) compressed films at 30 A.$^2$, magnification 13,500; (d) compressed films at 2 A.$^2$ (after collapse), magnification 8,100; (e) uncompressed films at 18 A.$^2$, magnification 10,700; (f) uncompressed films of low molecular fraction at 18 A.$^2$, magnification 10,700.

Arrows indicate the direction of compression

array of parallel microfibrils oriented at right angles to the direction of compression (Fig. 1,*d*).

Uncompressed films initially spread at a small area, for example, 18 A.$^2$/monomeric unit, gave winding microfibrils which had no sign of orientation (Fig. 1,*e*).

From the above results, it is evident that compression of the film gives rise to the formation of a large number of microfibrils which adopt an orientation at right angles to the direction of compression. It is to be noted that the mean size of the microfibrils remained almost unchanged during compression.

The effect of the degree c polymerization on the structur of surface films is also reveale by the electron microscope. I Fig. 1,*f* is shown the structur of uncompressed films of 6-nylo (*D.P.*8) spread at an area c 18 A.$^2$/monomeric unit. Compai ison of Figs. 1,*e* and 1,*f* show that the fraction of low mole cular weight produced thicke microfibrils than the fraction c high molecular weight.

Similar investigations have als been made with other crystallin polymers, for example, cellulos acetate and polyvinyl alcoho Secondary products of cellulos acetate (Celanese No. 3, wood-pul source) were dissolved in aceton and the hazy solution thus obtaine was spread on distilled water. Th uncompressed films, initially sprea at an area of 70 A.$^2$/monomeri unit, contained a large numbe of granules, the mean size of whic was estimated to be about 100 A but no fibrils (Fig. 2,*a*). Thes granules decreased in number cor siderably when the acetone sol tion was spread after centrifugatior so it is possible that they might b partly responsible for the haze i the solution[4]. Another sample c cellulose acetate, produced fror cotton linters (Celanese No. 1 also gave similar granules. Whe these films were compressed to les than 10 A.$^2$/monomeric unit, thi microfibrils appeared with a orientation at right angles to th direction of compression (Fig. 2,*b* Compressed films of polyviny alcohol also gave a similar fibrilla picture.

On the other hand, amorphou polymers, for example, polyviny acetate and polymethylmethacry ate, even when their films were con pressed to a very small area, ex hibited folds only, without an regular fibrillar substructure.

## egative Thixotropy of Aqueous Solutions of Polymethacrylic Acid

SUFFICIENTLY concentrated aqueous solutions of lymethacrylic acid (about 8–15 per cent, depending the degree of polymerization) form clear stiff gels room temperature. At somewhat lower concentra- on, such systems are sols. On heating, these sols n be converted into gels ; on cooling, the gelation completely reversible, the gels reverting to sols hich reach their original consistency after about hour.

A remarkable characteristic of these sols is their action to shear. A several hundred-fold increase consistency is easily induced by stirring or shaking. or example, a 5 per cent solution of polymethacrylic id of degree of polymerization 10,000 shows a 0-fold increase in apparent viscosity (from 5 poise 1,750 poise) after subjection, for about one minute, a rate of shear of 10 sec.$^{-1}$. More concentrated sols –10 per cent) will actually set to firm gels while ing stirred with a glass rod or simply when the ttle in which they are contained is shaken[1]. The ansformations are completely reversible, and the stems reach the original state about an hour after irring has ceased. Increase in the degree of poly- erization and higher temperature enhance the effect. his behaviour represents, to our knowledge, by far e most pronounced instance of 'negative' thixo- opy yet described in the literature[2].

Negative thixotropy is here understood to denote reversible isothermal increase in consistency during echanical treatment. In negatively thixotropic stems, the field of flow displaces the equilibrium the system from its state as a sol, at rest, to a gel ate of higher free-energy content which, on standing, ontaneously reverts to the sol state. Negatively ixotropic behaviour, therefore, is the exact opposite normal thixotropic behaviour, in which the state lower free energy, to which the system reverts ontaneously upon cessation of mechanical agita- on, is the gel state. Negative thixotropy should also distinguished from the well-known phenomenon work hardening, in which shearing only enhances e rate of the spontaneous process of crystallization, d from the phenomenon of dilatancy, described Osborne Reynolds, which is due to a special arrangement of rigid particles in a suspension.

The phenomenon of negative thixotropy is rarely countered. Even among those water-soluble lymers such as polyacrylic acid and polyacrylic d polymethacrylic amide, the structure of which is osely related to that of polymethacrylic acid, we iled to find signs of such behaviour. In fact, ost aqueous polymeric systems, for example, latine[3] and methylcellulose solutions[4], show normal ixotropy.

In our opinion, negative thixotropy in polymethacrylic acid systems is probably due to the fact that, *a priori*, more intermolecular bonds are likely to be formed in a field of flow than in a system at rest. During flow, the collision frequency between groups of different polymer molecules increases, permitting, other things being equal, the formation of a network, and the consequent appearance of gel behaviour. Since in a concentrated polymer solution we expect an equilibrium between intra- and inter-molecular bonding, the effect of the field of flow will be to shift this equilibrium towards a greater amount of cross-linking by intermolecular bonds.

The field of flow, however, acts in two ways. It not only builds up structure, as described above, but it also breaks intermolecular bonds that are insufficiently strong. Indeed, in the usual thixotropic systems, this second effect predominates. Apparently it is only in solutions of polymethacrylic acid, at the rates of shear investigated, that the first effect so largely predominates.

The intermolecular cross-links in polymethacrylic acid solutions seem to be hydrogen bonds between carboxyl groups on neighbouring chains. These bonds are indeed relatively strong, but their strength cannot be the only factor accounting for the negative thixotropy. As noted above, other substances strongly hydrogen-bonded, such as the polyamides and polyacrylic acid, do not form sols with negative thixotropy. Additional factors such as, for example, the relative stiffness of the polymethacrylic acid molecule, which may permit local, crystallite-like accumulations of hydrogen bonds, probably play a decisive part.

Despite their relative strength, the hydrogen bonds are breaking and re-forming at a considerable rate ; when mechanical agitation ceases, the initial state, with a higher degree of intramolecular bonding, is gradually approached. The gel structure thus breaks up and the original sol is re-formed.

## Photo-elastic Dispersion in Cubic Crystals

CRYSTALS of classes $T_d$, O and $O_h$ are characterized by the strain-optical coefficients $p_{11}$, $p_{12}$ and $p_{44}$, whereas those of the classes $T$ and $T_h$ have an additional coefficient[1] $p_{13}$. Using standard methods described elsewhere[2,3], the $p$ values at three wave-lengths of light for a few cubic crystals have been determined and are given in Table 1. In Table 2 the values obtained by me for some optical glasses are entered.

It is interesting to note that : (1) cubic crystals, in general, show photo-elastic dispersion ; (2) the values of $p_{11}$ and $p_{12}$ in potassium chloride and bromide increase with increasing wave-length, whereas in all other crystals their behaviour is opposite. The dis-

persion for these two coefficients in lithium fluoride is negligible[3]. The direction of variation in $p_{44}$ is the same in all crystals. The magnitude of dispersion of this coefficient is usually of the order found in glasses, except in lithium fluoride and lead nitrate, where it is large, being 60 to 80 per cent.

## Site of Inhibition of Trypsin by Diethyl *p*-Nitrophenylphosphonate

THE inhibition of proteolytic enzymes by organophosphorus esters has been the subject of intensive study in recent years[1]. Thus, the reaction of trypsin with di*iso*propyl fluorophosphonate[2] or diethyl *p*-nitrophenylphosphonate[3] has been shown to be accompanied by a loss in its esterase and proteolytic activity. Still unanswered, however, is the question whether these inhibitors combine with trypsin at the site responsible for enzymatic activity, or at another site, which, because of its strategic location, may interfere sterically with the enzymatic centre.

We recently reported[4] that trypsin remains enzymatically active in high concentrations of urea. At the same time an increase in the solubility of the enzyme in trichloroacetic acid was noted which suggested that perhaps some profound change in the structural configuration of the molecule may have occurred. In this event, some alteration in the normal spatial relationship of active centres that may be present might likewise be expected. The results reported here indicate that diethyl *p*-nitrophenylphosphonate does in fact react with trypsin treated with urea at a site which can be distinguished from the site responsible for proteolytic activity.

The trypsin used in this study was a twice-crystallized product (Worthington Biochemical Corp., Freehold, N.J.) which was freed of salt by dialysis against 0·001 *N* hydrochloric acid, followed by lyophilization. Diethyl *p*-nitrophenylphosphona was kindly provided by Dr. William Summerson, the Army Medical Center, Md.

The experimental procedure was as follow 1 mgm of trypsin was dissolved in 4 ml. of 0·05 borate buffer, *p*H 7·6, containing 8·3 *M* urea, a immediately treated with 1 ml. of $6 \times 10^{-3}$ *M* dieth *p*-nitrophenylphosphonate in *iso*propanol (one hu dred-fold excess on a molar basis). The mixture w allowed to stand at 25° C. A similar system fro which urea had been omitted contained 0·02 calcium chloride to minimize self-digestion of t enzyme. 1 ml. of *iso*propanol replaced the dieth *p*-nitrophenylphosphonate solution in controls set u to measure losses in activity not attributable diethyl *p*-nitrophenylphosphonate. Enzyme-fr controls were likewise necessary to correct for t spontaneous hydrolysis of the diethyl *p*-nitropheny phosphonate during the course of the reaction. A various intervals of time, the liberation of *p*-nitr phenol, the product of the reaction between tryps and diethyl *p*-nitrophenylphosphonate, was measure by the method of Hartley and Kilby[5]. Proteolyt activity was measured concurrently by the case digestion technique of Kunitz[6]. The results of th experiment are shown in Fig. 1.

In the absence of urea, the rate at which *p*-nitr phenol was liberated closely paralleled the loss proteolytic activity, a finding which is in comple accord with that of Kilby and Youatt[7]. In the pre ence of urea, a similar rate of release of *p*-nitrophen was observed. The maximum amount of *p*-nitr phenol liberated per given amount of trypsin w very nearly the same in the presence or absence urea. Of particular interest, however, is the fact th in the presence of urea the proteolytic activity of t

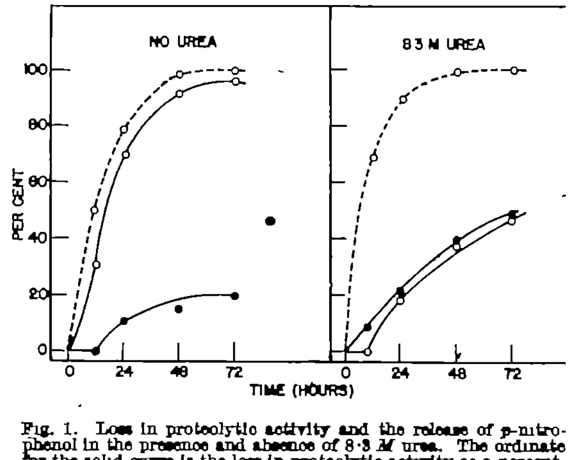

FIG. 1. Loss in proteolytic activity and the release of *p*-nitrophenol in the presence and absence of 8·3 *M* urea. The ordinate for the solid curve is the loss in proteolytic activity as a percentage of its initial value, and the ordinate for the broken curve is *p*-nitrophenol liberated as a percentage of its maximum value. ○, with diethyl *p*-nitrophenylphosphonate; ●, in the absence of diethyl *p*-nitrophenylphosphonate

zyme was essentially unaffected by diethyl p-nitro- enylphosphonate. The loss in activity that did sue may be attributed to the instability of the zyme which was apparent even in the absence of ethyl p-nitrophenylphosphonate (see curves drawn rough the solid circles).

In line with these results, it may be mentioned at inactive diethyl phosphoryl trypsin was prepared allowing trypsin to react with an excess of diethyl nitrophenylphosphonate followed by dialysis and ophilization. The proteolytic activity of this pre- ration could be partially restored (15–20 per cent) treatment with 8·3 *M* urea under certain con- tions.

These observations are in accord with a hypothesis at the site at which diethyl p-nitrophenylphosphon- e reacts with trypsin is not identical with the site hich is involved in the combination of trypsin with e protein substrate. Normally, the configuration the enzyme molecule is such that the site of action with diethyl p-nitrophenylphosphonate is in ose proximity to the enzymatic site, so that chemical odification of the former interferes sterically with e accessibility of the second site for substrate com- nation. The effect of urea, however, may be so to ter the configuration of the trypsin molecule that ese two sites are separated and free to exert their aracteristic activities. Whether the structural odification effected by urea involves an unfolding the molecule or fragmentation into smaller units a problem now under consideration.
